USING PAIR PROGRAMMING TECHNIQUES IN CLASSROOM ENVIRONMENT

Carlos Alberto Ynoguti[1], Afonso Celso Soares [2]

Abstract *— For several years, software development companies have been using pair programming with great success. Pair programming is a technique that consists of two programmers working together on the same computer to develop a computer program: one of them, the driver, operates the computer, and the other, the observer, examines the work of the driver, looking for errors and thinking of possible alternatives that can improve the solution. This procedure is closely related to Collaborative Learning philosophy, extensively used in elementary and high school teaching, with very good results. Unfortunately, its use in undergraduate courses, especially in the engineering area, is almost absent. Therefore, we decided to adopt pair programming in a first semester computer-programming course, both in theoretical classes and in laboratory practical classes. This paper reports the results of a one-semester course using pair programming.*

Index Terms — pair programming, collaborative learning, computer science learning, extreme programming.

INTRODUCTION

Traditionally, students find introductory computer science courses very frustrating (in our institution, about 30% of them fail the subjects at each semester).

With pair programming learning, two students work simultaneously to solve a task (an algorithm or a computer program). In this technique, one of the students is the "driver" and has control on the pencil/mouse/keyboard and writes the algorithm or the program. The other, called the "observer", continuously and actively examines the work of the driver, watching for defects, thinking of alternatives, looking up resources, and considering strategic implications of the work at hand. Examples of things noted by the observer are erroneous syntax, misspelling, and smaller logic mistakes, among others.

The student pairs apply a positive form of "pair-pressure" on each other, which has proven beneficial to the quality of their work products. At the end of the semester, the students were given a questionnaire about the pair-programming experience and most of them reported good impressions about this technique.

Also, this technique has proven to be beneficial for the teachers too. Some minor questions are answered inside the pairs. The number of exercises to correct is divided by a factor of two, enabling the teacher to give more exercises, and consequently, making a better evaluation of what issue is or is not being absorbed by the students. One important thing to note is that the number of cheating cases is reduced because collaboration is legitimized.

Cognitive theory can help explain why pair programming might be more effective than solo programming. In 1991 Nick Flor, a master's student of Cognitive Science at U.C. San Diego, reported on distributed cognition in a collaborative programming pair he studied. Flor recorded via video and audiotape the exchanges of two experienced programmers working together on a software maintenance task. In [3], he correlated specific verbal and non-verbal behaviors of the two programmers to known distributed cognition theories. One of these theories is "Searching Through Larger Spaces of Alternatives":

"A system with multiple actors possesses greater potential for the generation of more diverse plans for at least three reasons: (1) the actors bring different prior experiences to the task; (2) they may have different access to task relevant information; (3) they stand in different relationships to the problem by virtue of their functional roles. . . An important consequence of the attempt to share goals and plans is that when they are in conflict, the programmers must overtly negotiate a shared course of action. In doing so, they explore a larger number of alternatives than a single programmer alone might do. This reduces the chances of selecting a bad plan."

In this article, an experience involving pair programming learning technique in a first semester undergraduate computation course is presented. Advantages and disadvantages of this method are also presented and discussed.

Pair programming learning strategy is based on collaborative learning theory, which has been widely researched and advocated throughout the professional literature, mainly at the primary and secondary levels. For higher level courses, it's been adopted recently in some institutions with good results. This theory is further discussed in the next section.

COLLABORATIVE LEARNING

The term "collaborative learning" refers to an instruction method in which students at various performance levels work together in small groups toward a common goal. The students are responsible for one another's learning as well as for their own. Thus, the success of one student helps other students to be successful [5].

The collaborative learning points out the active participation and interaction, either between the students and the teacher or among the students.

Basic elements of collaborative learning

The basic elements of the collaborative learning method can be summarized into the following items[6]:

1. Group interdependency: the students, as a group, have a common goal and should work as an efficient team to reach it. The students are responsible for their own apprenticeship. This procedure helps in the apprenticeship of every member of the group.
2. Interaction: one of the goals of the collaborative learning is to develop the student's competence in working in groups. Each member of the group should accomplish his part of the task and spare some time to share his knowledge with his partner(s) and, on the other hand, receive the contributions of his partner(s).
3. Diverging thoughts: there shouldn't be a member that claims himself as the leader or the smart guy, but instead, a conscience that both of the members of the group can explain their own points of view, competence and perspectives. The activities should be created in order to demand collaboration instead of competition (complex tasks that require creativity and has several possible solutions).

Vygotsky's socio-cultural theory

The socio-cultural theory by Vigotsky about the learning process emphasizes that the human intelligence comes from our society and culture, and happens at first time because of the interaction with the social environment.

Another aspect of Vygotsky's theory is the idea that the potential for cognitive development is limited to a determined zone that he called "proximal development zone" (PDZ). He defines this concept as "the distance between the real development level, determined by the independent problem resolution, and the potential development level, determined by the problem resolution under a supervisor advising or in collaboration with more capable partners" [1].

It's important to consider that the PDZ varies with the culture, the society and the experience of each individual.

For a PDZ to be created, there should exist a joint activity that enables the interaction between teacher and students. The group work allows the confront and integration of different points of view, making the learning process richer and more interesting.

Of course, people learn by themselves naturally provided that there exist adequate and minimally stimulant contexts. However, if a teacher helps a student to analyze and reflect about his/her actions, the learning process is accelerated.

EXPERIMENTS

Class characterization

Before describing the pair programming tests results, it's instructive to characterize the classes they were performed. The studies were carried out in an undergraduate, first semester computing class. In our institution, classes have typically 70-100 students. The course is divided into two parts: a theoretical part (60 hours) and a practical one (30 hours).

In the theoretical part, the students learn how to construct algorithms to solve simple problems, and use a pseudo-code language to construct these algorithms. All the algorithms are written with pencil and paper and the students are continuously invited to debug their algorithms simulating the behavior of the compilers.

Now, in the practical part, the students are divided into smaller groups (20 to 25 students) and use the Delphi® compiler to create their programs.

Grades are distributed in the following manner: 2 theoretical tests and 3 practical tests, taken individually. Also, during the semester, 10 to 15 exercises are assigned and corrected, and add a bonus up to 10 points in the final grade (grades range from 0 to 100 points). Part of these exercises was done individually, and part with a partner, using the pair-programming technique.

In other words, the pair-programming technique was used as a learning method, not as an evaluating one, although part of the grading had been obtained using this technique.

Solo and pair programming tests

As reported earlier in this article, the pair programming technique was used in the classroom and laboratory exercises. In the first part of the semester, the students developed their activities working alone. Because of the class size (74 students) and the class dynamics (teacher was always solving students' doubts during the exercises), cheating was difficult to control, and it was common to see 4, 5 or even 6 exercises with identical (and wrong) solutions. It was clear from these results that only a few students did the exercises. The others just cheated. It was a frustrating result, because it's clear from these facts that students were more interested in the bonus points than in learning how to program.

To try to change this behavior, the students were told that if the teacher found more than two exercises with identical solutions, the grade would be divided by the number of identical exercises. After this, the number of cheating cases dropped, and so did the grades.

Of course, as a result of this scenario, the students' grades in the first tests were not good.

In the second part of the semester, they were given an article about pair-programming [2] to read and had a brief explanation about the new working method. After this, they were invited to test on the new working methodology. None of them was obligated to work in pairs, but the teacher encouraged them to try the method before deciding how they would like to work. These activities were done both in classroom, with algorithm design problems, and in the laboratory environment, with code design problems.

Pairs were formed in a free way. No constraints were made in this sense and, in general, the students chose their friends or the students that was seated nearby, and later, it was noticed that this procedure was an error, as shown in the next section.

At the end of the semester, the students were invited to answer some questions concerning the pair programming experience. The questions were extracted from a work by Williams & Kessler [2] with some minor modifications. The answers the students gave will be commented later in this article.

Results

Cheating cases dropped dramatically, and the number of different solutions raised enormously. Also, the solutions varied from very sophisticated ones to very complicated and inefficient ones, but the great majority of the designs met the specifications of the problems, a result quite different from the first part of the semester.

The classes became very noisy, but this was because the students were really discussing solutions and alternatives to solve the problems and actively participating in the class. Also, when students asked the teacher to clear doubts, they came with more elaborated questions, not trivial ones, so the easy answering doubts were cleared independently by the students.

Specifically in the algorithms made in class, syntax errors are very common because of the lack of a compiler that reports them to the programmer. With pair programming this kind of error dropped dramatically.

Now in the laboratory environment, it was noted that the students waste less time doing other activities (such as talking, surfing on the internet, etc.) because of the partner's pressure. Also, they learn not only the theoretical aspects of programming, but also get some tips from their classmates: hot keys, typing tricks, help usage and other things were learned just by observing the partner working.

A final feature of this method is that, as students work in pairs the task of correcting the exercises is approximately divided by a factor of two, and then it can be possible to give more exercises during the semester and keep a closer look on how the students are assimilating each part of the subject and reinforce the weak areas.

Questionnaire analysis

The questions taken from [2], and the most common answers, were:

1) *It has been said among teachers, "You do not know it unless you can teach it." Do you find any value to yourself in explaining your work to your partner?*

Many students reported that when explaining some subject to his/her partner, they had to elaborate it in a more detailed fashion, so they learned a little bit more and noticed several aspects of the subject during this process.

2) *Do you feel you have learned anything just by reading your partner's code?*

The great majority of the students answered "no" to this question. They reported that they learned almost nothing by observing their partners working.

3) *What was the biggest hurdle you have had to overcome as a collaborative programmer?*

Accepting another strategy, different from what they had traced in the principle, was the most common problem reported.

4) *What kinds of things does the non-driver do as he/she observes?*

Some syntax errors, erroneous indentation, and minor logic mistakes were the most frequently answers found.

5) *What do you think is the biggest advantage of collaborative programming?*

Most of the students reported that the big advantage of pair-programming is that they could perform better algorithms, with fewer errors and in less time.

One of the students reported an interesting fact: during one development section, he didn't know how to solve the first part of the problem, and his partner helped him. In the second part, the opposite happened, he found the answer that his partner couldn't. So, working separately, both of them would fail the exercise, but working together, they could accomplish their goal.

6) *What do you think is the biggest problem with collaborative programming?*

The main problem the students found in pair-programming practice was when their partners didn't accept different ideas or suggestions. Some of the students also reported that their partner simply did nothing, not cooperating for the solution of the problem.

Drawbacks

As any other learning methodology, pair-programming has its drawbacks too. Analyzing the questionnaire answers and based on our own observations, we can list the following drawbacks in using pair-programming methodology in a classroom environment:

Some students really dislike working in pairs, and prefer to work alone. Some of them not even tried to work in pairs, preferring to work alone, even scoring only poor grades.

Pair choosing is another aspect that must be addressed carefully. They must be formed with one student that has a higher knowledge/skill level than the other, so he/she can help his/her partner. Pairs with two low knowledge/skill level students didn't worked also, because none of them could help each other. A student with very low knowledge/skill level together with a very high knowledge/skill level is another kind of pair that doesn't work, because the "expert" student quickly becomes bored with his partner and resolves the problem alone, without explaining the solution to his/her partner.

Another thing that must be taken into account for the pair programming to work properly is the personality of the partners. In our classes, we observed that students with a dominant profile tend to not accept suggestions and critics and try to resolve things by themselves. On the other hand, passive students tend to accept their partners solutions and avoid giving opinions, even when they notice something that is clearly wrong.

The last thing we observed in our classes is that there are some students that became addicted to pair programming and could not develop solo programming anymore. Probably this is the case of a passive student that agrees with everything even not understanding what the partner is doing.

Conclusions and Future Work

In this article we described the pair-programming method when used as a learning tool and showed the relationship between this method and the collaborative learning theory and the Vygotsky's socio-cultural theory.

In general good results were achieved, and most of the students were satisfied with their own performance in the course. We noticed problems in some pairs due to great difference in knowledge, when one of the partners was too dominant or too passive, and when partners had personal differences.

Also, some students could not maintain the performance of pair programming when working alone. This fact may indicate that not all the problems would be solved in pairs; students have to have some problems to solve alone to identify their strong and weak points, and have a more realistic view of themselves.

In our institution, a psychological profile evaluation is made for all the students by a specialist, and for the next semester, this information will be used to try to avoid problems with dominant/passive partners in the working pairs. Also, the knowledge/skill levels should be used to form the pairs, and the first test of the semester can be used for this purpose.

DIRECTRICES PARA LA ACTUALIZACIÓN DE PROGRAMAS DE INFORMÁTICA EN ESPAÑA

Edmundo Tovar[i], Jesús Cardeñosa[ii]

Abstract *— Los Planes de Estudio de Ingeniería Informática se diferencian de los planes de otras disciplinas en que requieren una actualización frecuente debido al dinamismo de los conocimientos que incorpora y a distintas directrices propuestas por diversas instituciones u organismos. La efectividad de estos cambios puede controlarse a través de la valoración de indicadores de calidad de la titulación que normalmente son aplicados con fines de acreditación.*
En este artículo se analizan y organizan diferentes clases de directrices aplicables en la evolución que sufren los Planes de Estudio de titulaciones de Informática. Este problema se ilustra con un caso real de aplicación del uso de indicadores de calidad como una de los factores que deciden la necesidad de cambios en un Plan, y la aplicación de algunas de las directrices identificadas para la realización de una propuesta de actualización de un nuevo currículo de la titulación de Ingeniero en Informática de la Facultad de Informática de la Universidad Politécnica de Madrid.

Index Terms — Computer Science Education, Evaluation of Engineering Programs´ Quality, Models for Higher Education in various countries.

INTRODUCCIÓN

La Informática ha sufrido cambios drásticos durante la década pasada. Hay nuevas tecnologías que se introducen continuamente, y otras se quedan obsoletas. Los avances técnicos, como el de las aplicaciones para World Wide Web y las tecnologías de redes han incrementado la importancia de muchos temas curriculares.

Pero también ha habido cambios culturales. La informática se ha expandido enormemente gracias al desarrollo y las facilidades para el acceso a aplicaciones de software a través de Internet. Las TI tienen una creciente importancia en la economía han surgido las empresas tecnológicas, y la alta demanda de la industria para a atraer personal cualificado. Ello ha conducido a una mayor aceptación de la Informática como una disciplina académica.

[1] Jesús Cardeñosa, Facultad de Informática, Universidad Politécnica de Madrid, Campus de Montegancedo s/n, Boadilla del Monte 28660, Madrid, Spain, carde@fi.upm.es

La entrada de la tecnología de la información en los ámbitos culturales y económicos han consolidado el reconocimiento de la disciplina.

En definitiva, la Informática es una disciplina especialmente viva. En los últimos 10 años los cambios habidos técnicos y culturales han cambiado el diseño de un

Plan de Estudios en Informática, así como la forma de enseñarlo. En la actualidad el alcance es tan amplio que es difícil establecer los límites y considerarlo como una única disciplina.

Esta es la razón por la que en la última revisión del "Computing Curricula", el CC2001 [1] se ha desarrollado en diferentes volúmenes. Sólo uno de ellos ha sido publicado, el de Computer Science, mientras que aún no lo han hecho los de Computer Engineering, Software Engineering e Information Systems. La conjunción de todas estas especialidades, según el criterio de ACM y de IEEE, se complementan perfectamente y la educación de la Informática debe cubrir por lo tanto, el nuevo alcance de la Disciplina.

En este artículo se tratan dos de los aspectos fundamentales que pueden ayudar en la elaboración de nuevos planes de estudio en informática: los indicadores de control referidos a planes de estudio, y las directrices que pueden ser tenidas en cuenta. Finalmente se analizará el uso de esta información en la propuesta de un nuevo plan de estudios en informática.

LOS INDICADORES DE CONTROL

Las Universidades españolas usan un sistema de indicadores que hace posible que éstas cuenten con una información de calidad y con potencial estratégico en la que se fundamentan sus decisiones y con la que los implicados pueden tener un certero conocimiento y un diagnóstico preciso de su realidad.

Cuando una universidad quiere informar a sus miembros, a los responsables políticos o a la sociedad en general sobre su calidad se pueden utilizar diversos tipos de indicadores, con significado diferente desde distintas perspectivas, pues la calidad es un concepto multidimensional. Se puede informar de la calidad a través de distintos tipos de indicadores [2]:

- **Indicadores directos**: son los resultados que obtiene la institución cumpliendo sus funciones.
- **Indicadores de impacto**: medidas de valoración o satisfacción de la institución por

parte de las distintas audiencias con los colectivos implicados.

- **Indicadores indirectos**: medidas con información de sus entradas, de sus características organizativas, de sus recursos y de sus procesos de funcionamiento.

Bajo esta clasificación los indicadores que aquí nos interesan son un conjunto de indicadores indirectos que afectan al proceso de enseñanza aprendizaje y que viene representado por el Plan de Estudios. Así, los indicadores utilizados por las universidades españolas que guardan una relación directa con el Plan de Estudios están recogidos en la tabla I, todos ellos indicadores indirectos:

TABLA I

INDICADORES REFERIDOS AL PLAN DE ESTUDIOS DEL SISTEMA UNIVERSITARIO PÚBLICO ESPAÑOL

Denominación	Explicación
Dedicación lectiva del alumnado	Media de créditos en los que los alumnos de una titulación se han matriculado. Este indicador se puede usar para analizar si la carga docente está por encima o por debajo de otros posibles valores de referencia.
Prácticas requeridas	Es la relación entre el número total de créditos prácticos requeridos y el total de créditos aprobados en el plan de estudios, dando así la importancia que tiene la oferta de docencia práctica.
Optatividad requerida de la titulación	Es la relación entre el número total de créditos optativos y de libre configuración que ha de cursar el alumno a lo largo de la carrera y el total de créditos a cursar para obtener el título. Es una manera de indicar el peso específico de la optatividad.
Oferta de optatividad	Relación entre el número de créditos optativos diferentes ofertados y el número total de créditos que ha de cursar el alumnado. Valores altos reflejan una gran oferta de optatividad.
Prácticas en empresa	Relación de créditos que el alumno debe cursar en empresas u organismos públicos, y el número de créditos prácticos que debe cursar.

Estos indicadores forman parte de un catálogo de indicadores que son aplicables al conjunto de las universidades españolas, independientemente de la naturaleza de sus disciplinas, humanas sociales o técnicas. Pero no basta con ofrecer información, sino que hay que contar con referentes para su contraste que permita decidir si el Pan de Estudios es mejor o peor. Por eso aquí se comenta también un sistema de indicadores específicos para titulaciones técnicas que forman parte del método de evaluación SECAI [3].

Los indicadores correspondientes al Plan de Estudios, según este método, se encuentran organizados en tres apartados:

- aquellos referidos al **proceso de elaboración**: indican en qué medida los elementos representados por el indicador, aparentemente, a elaborar un plan de estudios de calidad.
- Respecto del **contenido** del Plan de Estudios: señalan en qué medida los elementos representados por el indicador se manifiestan de la manera esperada en un plan de estudios de calidad.
- Sobre la **puesta en marcha**: representan en qué medida los elementos representados por el indicador se manifiestan de la esperada si el proceso y seguimiento del Plan de estudios es o fue de calidad.

TABLA II

INDICADORES REFERIDOS AL PLAN DE ESTUDIOS DEL SISTEMA DE EVALUACIÓN SECAI

Categoría	Indicadores
Proceso de elaboración	- Participación de agentes externos en la carrera - Participación de los miembros de la comunidad académica - Definición de ámbitos y perfiles profesionales de los titulados en función de la demanda social. - Análisis y valoración de los conocimientos, capacidad e intereses de los estudiantes que acceden a la carrera. - Análisis de la congruencia entre contenidos, métodos y recursos en función de los objetivos. - Posibilidades de logro en función del tiempo disponible para cursar el Plan.
Contenido	- Definición expresa del modelo de formación y de los objetivos educativos de la carrera - Estructura del Plan de estudios - Orientaciones metodológicas y su adecuación a los objetivos - Orientaciones relativas a la evaluación de conocimientos y su adecuación a los objetivos - Plan académico de cada asignatura - Contenidos de las enseñanzas. Actualización y adecuación a los objetivos - Previsión de actividades de nivelación y refuerzo
Puesta en marcha	- Previsión de las necesidades de acuerdo a los contenidos del plan - Nivel de conocimientos y aceptación del Plan por parte de los miembros de la comunidad educativa - Programa de seguimiento, evaluación y actualización del Plan

SECAI, por tanto, es más exhaustivo en la relación de indicadores que utiliza con respecto del Plan de Estudios, pues no sólo trata aspectos relacionados con sus contenidos sino con el proceso de elaboración, y su seguimiento. Su orientación a la evaluación de estudios técnicos se manifiesta al dar especial relevancia a la participación de agentes sociales en su elaboración y en la definición de perfiles profesionales, así como en el seguimiento en la actualización de contenidos. Además la descripción de cada indicador es más formal respondiendo mejor a un espíritu ingenieril, incluyendo información como criterios orientativos que deben utilizarse para evaluar el indicador, o la lista de informaciones (institucionales o resultados de encuestas) que son necesarias y están disponibles. Esto hace posible prácticamente la aplicación y evaluación sistemática de los indicadores.

Con el apoyo de la Comisión Europea, el consorcio Career Space [4], que está constituido por once importantes empresas de Tecnologías de Información y Comunicación (TIC) y por la Asociación Tecnológica Europea de Industrias de la Electrónica, la Información y las Comunicaciones, ha estado abordando la escasez de profesionales en este sector. Aparte de las iniciativas que tomaron, y que serán referidas más adelante, recomiendan que las universidades deben introducir un proceso de control de la calidad con resultados documentados. Y que la información obtenida debe aplicarse para seguir perfeccionando el programa. Según este consorcio, el proceso de control de calidad debe obtener retroalimentación del sector empresarial respecto a la evaluación de competencias de los antiguos estudiantes en áreas técnicas y de comportamiento después de su contratación. También requiere, partir de los comentarios de los estudiantes, conocer en qué medida el curso consigue los resultados esperados, y si el estudiante piensa que durante el curso ha adquirido los conocimientos y capacidades adecuados de cara al mercado laboral.

ORGANIZACIÓN DE DIRECTRICES

Hay distintas formas de clasificar y organizar las directrices que pueden considerarse en la renovación de planes de estudio de titulaciones de Informática. Dependiendo de quienes son las entidades que las elaboran pueden distinguirse directrices propias de las Asociaciones profesionales de reconocido prestigio, instituciones gubernamentales que tienen a su cargo la política educativa de un país o de una región que intenta armonizar las correspondientes a distintos países, las promovidas por las propias universidades, o las propuestas por el tejido empresarial a través de estudios de demanda de empleo.

En adelante se ilustrarán estas diferentes directrices con ejemplos en el contexto europeo y español, a los que pertenece el centro universitario que se tomará como caso real de actualización de plan de estudio.

Directrices de Asociaciones profesionales

Los estudios universitarios de la titulación de Ingeniería Informática en España se han basado tradicionalmente en los curriculums elaborados conjuntamente por los esfuerzos conjuntos de las asociaciones IEEE y ACM. En 1998 estas organizaciones formaron un grupo de trabajo para diseñar el Comuting Curricula 2001 [1], con el fin de llevar a cabo una importante revisión y mejora del anterior, fechado en 1991 [5]. Los principales cambios residieron en considerar los cambios tecnológicos, y cambios culturales en los últimos diez años. Por otra parte, el término computación se ha ampliado en estos últimos años hasta tal punto que es difícil definirlo como una única disciplina. Por ello decidieron desglosar el currículo en cuatro bloques: Computer Science, Computer Engineering, Software Engineering e Information Systems.

Directrices Gubernamentales

La universidad española inició un camino hacia un marco de autonomía e independencia con la Ley de Reforma Universitaria, en 1983. Los aspectos más novedosos fueron el régimen estatutario de las universidades, la organización departamental y la reforma universitaria mediante la ordenación académica de las enseñanzas. Al Consejo de Universidades, creado en 1985 con tal fin, le fue atribuido la competencia de proponer al Gobierno los títulos con carácter oficial y validez en todo el territorio nacional, como las directrices generales comunes y de homologación.

En 1987 se publican las Directrices Generales comunes de todos los planes de estudio de ámbito nacional y de carácter oficial [6], que establece que éstos deben ser elaborados por las universidades y posteriormente homologados por el Consejo de Universidades. Este marco legislativo presenta como aspectos fundamentales:

- **Flexibilización**: se distinguen tres bloques de materias. Troncales (contenidos mínimos comunes que deben incluir los planes conducentes al mismo título), Obligatorios (representan el carácter distintivo de la universidad), Optativas (representan una orientación elegida por el alumno para su formación), Libre configuración (con contenidos formativos que el alumno desea adquirir no directamente relacionadas con el título al que opta).
- **Estructura cíclica**: el primer ciclo comprende enseñanzas básicas y de formación general, y el segundo ciclo se dedica a la profundización y especialización en las enseñanzas. Los estudios de primer ciclo tienen duración de dos o tres años, y el segundo ciclo de dos años. La carga lectiva oscila entre 60 y 90 créditos por año académico, teniendo un crédito un equivalente de 10 horas de enseñanza.

Las directrices propias de cada titulación establecieron posteriormente el marco general que hizo compatible un mínimo de homogeneidad entre las distintas titulaciones oficiales, pues incluían la estructura y duración de las correspondientes enseñanzas, los objetivos formativos y el perfil profesional, indicando su número de créditos, su adscripción a áreas de conocimiento y una breve descripción de sus contenidos temáticos. De licenciatura y diplomatura en Informática se pasa a titulaciones de Ingeniero en Informática [7]. Según estas directrices, la carga lectiva no podía ser inferior a 300 créditos ni superior a 450. La carga lectiva semanal debía oscilar entre 20 y 30 horas, incluidas las prácticas (la carga teórica lectiva no podía superar las 15 horas semanales). Las enseñanzas prácticas consumen entre el 40 y el 50% del total de los créditos. Las materias troncales debían consumir un mínimo de 69 créditos y las de libre configuración el 10% del total.

Por otro lado, en loso últimos años se está creando el espacio europeo de la enseñanza superior, nacida en la Declaración de Sorbonne el 25 de Mayo de 1998 [8], donde se enfatiza el papel central que tienen las universidades para el desarrollo de las dimensiones culturales europeas. Posteriormente en la Declaración de Bolonia [9] los ministros europeos a cargo de la educación superior de 32 países firmaron una declaración conjunta en donde aceptan el desafío de construir el área europea de educación superior, frente a la tradicional independencia y autonomía de las universidades. Los objetivos propuestos se reagrupan en torno al pilar esencial de la valoración de la calidad para dotar al espacio europeo de confianza, pertenencia, movilidad y compatibilidad.

Directrices de Universidades

Los estudios universitarios de la titulación de Ingeniería Informática en España están organizados de distinta múltiples maneras, con universidades que sólo tienen un título o con otras que tienen una oferta en Informática con titulaciones de primer y segundo ciclo. En este último caso, incluso se dan casos en que el primer ciclo de la carrera superior es realizado por la Ingeniería técnica, y en otros o bien coexisten en el mismo o distintos centros de la titulación técnica y superior con variantes que van desde un determinado cupo de alumnos para acceder al segundo ciclo hasta planes de estudio que no facilitan el acceso de los ingenieros al segundo ciclo. Además, ha aparecido una enseñanza superior no universitaria tanto pública como privada que obliga a reconsiderara los estudios universitarios de informática. Ante esta heterogeneidad comienzan a existir unas directrices comunes, aunque no de obligado cumplimiento, que son discutidas y acordadas a través de la "Conferencia de Decanos y Directores de Informática" (CODDI), Conferencia que reúne a los responsables de la titulación de todas las universidades públicas y privadas españolas. En la actualidad el tema que ha centrado los debates se ha referido a determinar unas directrices comunes que permitan la adaptación de los estudios de las Ingenierías en Informática a la Declaración de Bolonia.

Los objetivos propuestos por la CODDI [10] han partido de la base en que la evolución de los planes de estudio basados en Bolonia debe cambiar la estructura emanada de la Ley de Reforma Universitaria en algunos aspectos importantes. En cualquier caso, se deben considerar tres elementos importantes:

- La informática forma una unidad que no permite diferenciar desde el principio de los estudios de informática de primer y segundo ciclo.
- Hay que incorporar otros conocimientos no estrictamente técnicos, como capacidades de negocio, sociales e individuales.
- Se deben mantener de la LRU dos conceptos básicos: las materias troncales y el catálogo de titulaciones.

Una vez constatados los inconvenientes de la especialización en el primer ciclo y la generalización en el segundo, para implantar las recomendaciones de Bolonia la opinión de la CODDI es que hay que adoptar una estructura en forma de un único primer ciclo, de 4 años, con una fuerte troncalidad que permitiera el acceso un segundo ciclo cuyo énfasis sería la especialización y la profesionalización, con muy poca o ninguna troncalidad, o bien el acceso al doctorado.

Las directrices proporcionadas se refieren a:

- Tamaño del Plan , utilizando como unidad de medida el Crédito europeo (ECTS). En concreto, entre 224 y 260 ECTS, siendo un crédito ETCS equivalente a 25 horas de trabajo para los estudiantes, incluyendo asistencia a clase, desarrollo de actividades y prácticas, estudio personal, asistencia a exámenes. Si se tiene en cuenta que un curso académico tiene una duración de 40 semanas, se puede aconsejar que la carga por semana para el alumno esté entre 35 y 40 horas.
- Distribución de materias de corte genérico, de arquitectura y tecnología de computadoras, de software y de proyectos para el primer ciclo.
- Para el segundo ciclo se dan sugerencias sobre materias de Arquitectura y Diseño Software, Desarrollo de Aplicaciones Software, Especialista de Sistemas de Información, Diseño de Sistemas Multimedia y Interacción Persona-Máquina, Telemática, Integración y Prueba o de Implementación y Prueba, Soporte Técnico, Diseño de Productos Digitales, Gestión de la Tecnología y de Proyectos, Informática Industrial y Sistemas Empotrados.

Directrices de empresas

En España la profesión informática no está bien definida, pues se convive con una gran variedad de títulos, tanto públicos como privados, a los que hay que añadir los diplomas públicos de enseñanza no reglada. Ante este problema de diferenciación profesional esta titulación está en permanente competencia con las Ingenierías de Telecomunicaciones, la Ingeniería Industrial y las licenciaturas en Físicas y Matemáticas, así como con titulaciones revestidas generalmente como "certificaciones" procedentes del sector empresarial, como Microsoft, Sun, Oracle o Cisco.

Frente a este problema de diferenciación el consorcio Career Space [4] cree que no existe una forma única de diseñar el currículo ideal en esta materia. Primero ha definido una serie de perfiles de capacidades genéricas básicas que se ofrecen como punto de referencia para las universidades. Pero aunque cada universidad tiene que encontrar por su cuenta la mejor solución, este consorcio ha elaborado un conjunto de directrices útiles cuya aplicación puede ayudar a las universidades a encontrar su propio camino hacia el éxito. Después de hacer un análisis de las tareas específicas de un trabajo en particular se llegó a la conclusión de que aunque las demandas de las empresas pueden ser distintas según la tarea que tienen que realizar, la estructura básica de los conocimientos necesarios es la misma. Esta es la razón por la que se pueden dar directrices comunes. Éstas fueron:

- Las calificaciones técnicas necesarias tienen un amplio espectro de conocimientos en matemáticas, ciencia y tecnología. Esa base es un requisito importante para que los graduados se puedan comunicar con colegas de otras áreas por medio de un lenguaje técnico común. Esa base se puede distribuir en un 30% de base científica, para comprender los métodos científicos para el análisis y el diseño, otro 30% de base tecnológica, que proporciona una visión general de las distintas tecnologías disponibles, y un 25% de conocimiento básico de sus campos de aplicación, de sus aplicaciones particulares según las demandas del lugar de trabajo para el perfil de un puesto de trabajo particular.

- El profesional de las TIC requiere la aplicación y el desarrollo continuos de las capacidades personales y empresariales por medio de proyectos en equipo, negociaciones, o presentaciones. Por eso se debe prestar una atención especial a la integración de la enseñanza de estas capacidades personales y empresariales esenciales en áreas temáticas más técnicas, que deben ocupar al menos el 15% del currículo.
- No basta con aprender cuestiones técnicas, sino que además hay que utilizarlos en situaciones reales, y conocer los problemas relacionados con los derechos de propiedad intelectual y el secreto comercial. Para conocer estas cuestiones, el consorcio recomienda realizar prácticas empresariales durante un período mínimo de tres meses. De esta manera se ayudará al alumno a elegir el tipo de trabajo que le gustaría encontrar después de graduarse.
- Para adquirir las capacidades profesionales es importante dedicar al menos tres meses a un trabajo en proyecto, aunque sea difícil evaluar el trabajo de un alumno individual.

El informe PACET [11] (Propuesta de acciones para la formación de profesionales de electrónica, informática y telecomunicación), promovido por ANIEL (Asociación Nacional de Industrial electrónicas y de telecomunicaciones), y el Colegio Oficial de Ingenieros de Telecomunicación, ofrece un análisis sobre el déficit de profesionales TIC en España, pero adaptando aquellos perfiles propuestos por Career Space a las demandas profesionales, identificando un total de 20 perfiles. Entre las recomendaciones recogidas en este informe destacan las siguientes:

- Recoger información sobre los perfiles profesionales, las habilidades requeridas, su oferta y la evolución en el mercado.
- Participación en los diseños curriculares de las empresas y las administraciones.
- Dar más peso a la formación de las tareas de gestión.

Este informe no ha recibido una aprobación unánime entre los colectivos implicados. Las principales críticas han sido realizadas por los Colegios de Ingenieros en Informática existentes en España. No se han tratado las acciones formativas que se precisan para el reciclaje profesional, ni se ha contemplado la formación precisa de perfiles de máxima responsabilidad de las áreas de Dirección de las TIC. Además se llega a recomendar un perfil de ingeniero superior para perfiles de programado de aplicaciones lo que demostraría un desconocimiento de los autores del informe de las titulaciones universitarias de Ingeniería en Informática y Telecomunicación.

En cualquier caso parece que existe un desfase entre la definición de perfiles obtenidos con respecto de las competencias y habilidades definidos en los planes de estudio de informática, por lo que la aplicación de estas últimas recomendaciones suponen asumir un riesgo.

UN CASO REAL: LA FACULTAD DE INFORMÁTICA DE LA UPM

En la Facultad de Informática de la Universidad Politécnica de Madrid, se llevó a cabo por primera vez un proceso de evaluación de la calidad en el año 2000.

Una de las tareas previas consistió en definir con precisión los indicadores a evaluar. Se tomaron como referencia los siguientes métodos, además de la Guía de Evaluación del Consejo de Universidades: el método SECAI (Sistema de Evaluación de la Calidad de Ingenierías), y el modelo europeo para la Gestión de la Calidad Total (EFQM). Se incorporaron nuevos indicadores que no fueron contemplados por la Guía del Consejo de Universidades. Como resultado se seleccionaron y describieron 66 indicadores relacionados con el área de enseñanza, 37 del área de Investigación y 34 correspondientes al área de tercer ciclo.

En la tabla III se resumen los resultados obtenidos referidos al Plan de Estudios:

TABLA III
RESUMEN DE CARENCIAS DETECTADAS EN EL PROCESO DE EVALUACIÓN REFERIDOS AL PLAN DE ESTUDIOS EN LA FI DE LA UPM

Categorías de indicadores	Puntos débiles
Estructura del Plan de Estudios	- Falta de definición de perfiles en el Plan de Estudios - No existe documentación registrada en la elaboración del Plan de Estudios - No hay especializaciones - Desequilibrio teoría-práctica en algunos casos. La carga real práctica es excesiva
Programas de Asignaturas	- Falta de datos para poder valorar la adecuación y coherencia de los programas de asignaturas - Falta de coordinación en la planificación de las prácticas
Organización de la Enseñanza	- Escasa participación del profesorado en la dirección de TFC - Tamaño excesivo en número de alumnos de los grupos

En paralelo, pero una vez elaborado el Informe final de evaluación de la titulación [12], un grupo de trabajo en el centro recibió el encargo de realizar una propuesta de un nuevo Plan de Estudios para que fuera debatido por los colectivos de la FI [13]. En concreto se tomaron en cuenta las siguientes directrices:

- Planes de Estudio en informática de otras universidades españolas (por ser de nuestro entorno más cercano), europeas (por la necesidad de converger con sus enseñanzas de referencia), y universidades de EEUU (por ser un país de referencia en temas informáticos). La información ha sido de utilidad para confirmar el rango de posibilidades y alternativas en la enseñanza de la informática.
- Computing currículum de ACM y de IEEE de 2001. En la actualidad es el único marco genérico internacional existente sobre curricula. Pero se ha encontrado con dificultades en aplicarlo pues la unidad de crédito no es equivalente, y el alumnado entre en la universidad con diferentes conocimientos.
- Boletín Oficial del Estado 20-11-1990, donde se establece la troncalidad mínima. Es de obligado cumplimiento para su homologación.
- Encuesta a profesionales informáticos, para conocer más de cerca la demanda profesional en nuestro entorno más cercano.
- Encuesta sobre los coordinadores de asignaturas con respecto de los contenidos de asignaturas, para asegurar el escalonamiento de las asignaturas relacionadas con el plan actual.

CONCLUSIONES

La actualización de Planes de Estudio en Informática es una tarea habitual para las universidades dada la actualización continua que requieren los contenidos técnicos que hay que transmitir, como la indefinición, quizás debida a su juventud, de la profesión informática. En este artículo se han recogido, descrito y organizado las directrices propias para este fin aplicables en el contexto español y europeo.

En la experiencia de una propuesta de un nuevo Plan de Estudios que se ha seguido se han utilizado la mayor parte de las directrices mencionadas. Algunas de ellas porque forman parte del marco jurídico español. Otras porque son directrices de reconocido prestigio. Pero las ha habido que no han sido utilizadas porque los proponentes han considerado que esas recomendaciones sólo cubren parte del problema o porque han aparecido tan recientemente que no ha sido posible aplicarlas. Este es el caso del efecto de la Declaración de Bolonia, y de los esfuerzos de armonización conjunta entre todos los directores de titulaciones en Informática. En cualquier caso es necesario tener en cuenta los nuevos perfiles profesionales, y tener en cuenta las habilidades básicas que requieren los nuevos profesionales en el sector.

Es decir, afortunadamente cada vez hay más directrices adecuadas para la elaboración de un plan de estudios en informática, aunque no todas las necesarias. Pero simultáneamente hay un esfuerzo cada vez mayor en la definición precisa de indicadores que controlen la calidad de los planes implantados. El conocimiento de estos indicadores ayudan a su vez como guías para recopilar las directrices necesarias.

A LARGE SPEECH CORPUS DEVELOPMENT

Carlos Alberto Ynoguti[1], Thiago Pereira Raposo [2] and Fabrício Vital [3]

Abstract *— Speech recognition systems use statistical methods based algorithms, and therefore need several training samples to perform properly. Consequently such systems require huge databases for training and testing. Large speech corpora development are hard to construct, and in Europe and in the USA, their development was possible only with the cooperation among research centers, universities, private companies and the government. In these countries, the availability of such databases provided the resources for the great improvement in speech technologies observed in the last years. Here in Brazil, such consortiums are not even mentioned, and the researchers have to work with small, locally developed databases. In this article we report an effort to develop a large speech corpus for the Brazilian Portuguese to fulfill this important lack for research in this area.*

Index Terms — speech processing, speech recognition, speech corpus.

INTRODUCTION

Spoken language is the natural way human beings use to communicate each other. Its structure is based on phonological, syntactic and prosodic structures of the language, on the acoustical environment, on the context in which the speech is being produced (e.g. people speak differently in noisy and silent environments), and on the channel through which it is transmitted (telephone channel, microphone, etc.)

Each person produces the speech in a different way, and the differences are due to differences in accent, shape and size of vocal tract, rhythm, among other factors. Furthermore, speech patterns are modified by the physical environment, social context, and speaker physical and emotional conditions.

The most promising technologies in speech recognition (Artificial Neural Networks and Hidden Markov Models [6][9][12][13]) use statistical modeling techniques that learn by examples. To provide this training samples, the training database must be large enough to cover all the phonetic, linguistic and acoustic phenomena encountered in spoken language. In fact, bad modeled variables (such as channel or microphone differences, out of vocabulary words, bad trained subunits) cause a devastating effect in the system's overall performance. So, in order to provide sufficient training samples for the statistical methods to work properly, the training database should be large enough.

Speech synthesis and coding do not require such large databases but need some material for evaluation and testing.

Unfortunately, such databases are very expensive to construct. These high costs can only be accomplished by a joint effort of private institutions, research centers and public funding agencies, in order to distribute tasks and avoid doubling efforts. Also, to involve more people in this process, this material should not be specific to one area or task, but instead, serve to as many groups and research areas as possible, in several knowledge areas (speech coding, synthesis and recognition, phonetic and linguistic studies, etc.)

In Brazil, due to the disinterest of the private sector and the lack of government incentives, there is no such speech corpus available in public domain. Some private companies, such as IBM, had speech corpus in Brazilian Portuguese, but unfortunately they are for private use only.

In Brazil, such consortiums were not even contemplated, and the researchers here have to develop their research using small, locally developed databases, which try to cover the most significant aspects of the spoken language, unsuccessfully in the great majority of the cases.

For this reason, a large speech corpus is of great importance for this area to achieve the great development verified in Europe and in the USA. A 500 speakers database seems to be a reasonable goal, comparing to European databases [2][3].

The final point is that this work has a purely scientific approach, that is, it's not intended to earn money

SPEECH DATABASES AROUND THE WORLD

In Europe, France, Portugal, Italy, Germany, Greece, England, Denmark, Spain, Norway, Sweden and the Netherlands, joined in the EUROM_1 project [2], there is a multinational effort to create a speech corpus in the languages spoken in that countries. For each country, a database consisting of 60 speakers (30 males and 30 females), selected in the same way and recorded in the same conditions with common file formats was created.

In Portugal, it was also created a database called BD-PUBLICO (Base de Dados em Português eUropeu, vocaBulário Largo, Independente do orador e fala

[1] Carlos Alberto Ynoguti, INATEL National Institute of Telecommunications, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, ynoguti@inatel.br

[3] Fabrício Vital, INATEL National Institute of Telecommunications, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, fvital@inatel.br

COntínua), with about 10 million words in approximately 156 thousands sentences, pronounced by 120 speakers (60 males and 60 females). This speech corpus was developed by a joint effort of research centers, the government and some private institutions [3].

In the USA a great effort was made in this sense and there are available in the public domain several speech databases for development and evaluation of speech processing systems.

The Linguistic Data Consortium [8] is an open consortium of universities, companies and government research laboratories. It creates, collects and distributes speech and text databases, lexicons and other resources for research and development purposes. The University of Pennsylvania is the LDC's host institution. The LDC was founded in 1992 with a grant from the Advanced Research Projects Agency (ARPA), and is partly supported by the Information and Intelligent Systems division of the National Science Foundation. Most of the well known speech corpora (TIMIT, TI-DIGITS, SWITCHBOARD, Wall Street Journal, etc.) are available at LDC.

Also, research centers as the Center for Spoken Language Understanding from Oregon Graduate Institute are making solo efforts to construct particular databases [4][5].

In the United States there are also many speech corpora available in public domain for speech systems development and evaluation.

The availability of large databases allowed an expressive improvement in the speech technologies, not only by alleviating the task of corpus development, a hard and expensive task, but also by providing a way to compare the results achieved by different researchers in a statistically significant way.

METHODOLOGY

The goal of this work is to be an initial step to the construction of a large speech database. The idea is to distribute an acquisition software among the researchers interested in this kind of material and ask them to contribute with some speakers. With contributors in all regions of the country, it would be possible to quickly construct a large corpus at a very low cost. In this sense, researchers of many universities are being contacted to help in this effort.

It is intended to collect recordings that contemplate the majority of the applications in speech technology, such as machine commands, continuous speech, connected digits and others.

Eventually, this database could became a reference in the speech area, allowing researchers to implement and test their ideas, and to compare their results in a statistically consistent way. Also, the methodology used to generate the database allows it to be in continuous expansion.

To achieve this goal, the whole project was divided in the following stages:

- Study of dialects and geographic distribution of the speakers.
- Determination of the types of locution
- Acquisition software development
- Recordings
- Phonetic transcription
- Organization of the database

Next, each topic will be described in more details.

Study of dialects and geographic distribution of the speakers.

For a database to be representative, it’s necessary that it has utterances from people representing all the accents found in the country. It’s not an easy problem and, in fact, neither the number of different accents nor the accents themselves are determined for Brazilian Portuguese.

Another problem one has to face is how many people to record from each region/accent? Which criterion should be used? The first idea that comes to mind is: the percentage of speakers of one determined region must be proportional to the number of inhabitants of that region. However, other factors have to be taken into account:

- Percentage of the people who will really use the speech technology;
- Economic importance of each region;

Clearly, these issues are not easy to handle and further study must be done in order to have a truly representative speech corpus. Despite of these issues, it’s necessary to define the number of speakers to be collected from each region, and for the first approach, the intention is to collect as many speakers as possible. Afterwards, when (and if) these linguistic studies become available, it’s always possible to collect more utterances in order to balance the database.

Determination of utterance types

The goal here is to cover all the possible applications of speech technology. After long research and exhaustive discussion, one decided to contemplate the following topics:

- **Continuous speech.** (“My son is sick and I’ll bring him to the doctor.”) – 20 utterances per speaker. In order to model all the phonetic and grammatical variations, it is interesting that this database should be as assorted as possible. Good sources of such kind of sentences are the newspapers, the internet, magazines, books and others. Up until the moment, about 10000 sentences were collected, and it’s expected to collect material enough for 1000 speakers (20000 sentences). Of course, it’s a hard and tedious work, and an acquisition software was developed for this purpose. Also, sentences were limited to have 8 to 12 words each, so that there are not too short or too long ones.It is desirable that the set of sentences sent to each speaker has at least one sample of each phoneme. Being thus, the verification of the phonetic content of the sentences assigned to each speaker becomes necessary. In the case of absence of some phoneme, one of the sentences is substituted for one that contains the absent phoneme. The counting and verification of phonemes is executed through an automatic transcription software, developed by the researchers of the Institute of Studies of the Language of the University of Campinas.

- **Connected digits.** ("five seven eight oh six zero two one") – 5 utterances per speaker. For this part, a software was developed to generate sequences of 4 to 8 digits in a random fashion.
- **Numbers in full.** ("two hundred thousands, three hundreds and forty") – 5 utterances per speaker. As in the previous case, a software was developed to generate random numbers and to transcribe them for the speaker to read.
- **Isolated words.** ("open", "print", "left", etc.) – 5 sets of 5 utterances per speaker. These words were chosen to meet applications such as computer operation, machine operation, banking services, etc. For each speaker, a set of 25 words is chosen in a random manner. For balance, it was not allowed for the same speaker to utter the same word twice, and the number of occurrences of each word in the whole database is set to be equally distributed.
- **Spelled words.** ("S-H-A-K-E-S-P-E-A-R-E") 5 utterances per speaker. Usually, the application of this kind of utterance is to give a name for a given service (e.g. banking service, air travel reservation), specially for foreign names. So, the speakers are asked to spell their first name, their last name, the first name of their father and mother, and the last name of the city they live.
- **Semantically unpredictable sentences.** ("Blue lions fall from Java's basements.") - 5 utterances per speaker. Semantically unpredictable sentences like the one from the example above are used for speech synthesis systems evaluation: when the listener cannot predict which word will be pronounced next, it's necessary to really understand what was spoken.
- **Sentences for prosodic study**. 4 to 8 utterances per speaker.
  1. "I **see** the **sea**"
  2. "I **see** the blue **sea**"
  3. "The blue **sea** is what I **see**."
  4. "I **see** that you want to go to the **sea**."

  The sentences listed above (and similar sets) are intended to evaluate the prosodic aspects of words uttered in different positions inside the utterance. Further, each sentence should be uttered in three different ways (slow, normal and fast) so that one can construct rhythm models of speech.
- **Spontaneous speech.** 1 utterance per speaker. The application for this topic is human-machine interface, and word spotting methods. For example, for utterances like "I'd like to know my credit card number", "Please tell me my credit card number", the system must understand that the information required is the credit card number. The idea here is to create situations in which the speaker is asked to formulate a question or make a comment about some topic. Examples of motivating questions are:
  "Ask for information about the movies for tonight."
  "Make a comment about the weather"
  "Ask for a pizza on a delivery service"

Construction of the acquisition software

The acquisition software is one of the most important part of this project because it will make it possible the acquisition of the utterances in a fast and low cost way. This software performs the following tasks:

- Before starting the recording session, speakers fill a register with their name, surname, age, sex, education level, profession, city where he was born, name of the father and the mother and cities where he lived. This last item has great importance because accent is defined until the fourteen years of age. The father and mother's names are asked for the spelled words section.
- After the registration part, the speaker goes to the recording session. The acquisition system shows the sentence to be uttered in the computer screen, together with recording controls, so that the recording can be made in an easy way. Also, the system check for recording saturation and, if this occurs, the speaker is asked to repeat that sentence.
- Recordings concluded, the software sends the information via ftp protocol to Inatel, so that the data can be stored and organized.

Recordings

The recording task will be distributed among the people who are interested in collaborate with this effort. An instruction manual was elaborated and will be distributed together with the software, with directions about the microphone type, recording environment, sound card type, registration and sending procedures.

For this first version of the database, it's intended to collect utterances in a office environment, with a good quality microphone.

Phonetic transcription

The ideal would be that the utterances could be manually transcribed by linguistic specialists team. But this involves costs and, at the moment, due to lack of financial resources, this task will be carried out automatically, using a software developed at the Institute of Language Studies (IEL) of the State University of Campinas (UNICAMP).

Database organization

As the recording stage ends, it is necessary to organize them in order to facilitate their manipulation. It is intended to divide the speakers into training and test sets. Also, the speakers can be clustered in terms of age, gender and accent. For this purpose a SQL based software is being developed.

CONCLUSION AND FUTURE WORK

In this article, a large speech corpus development effort is described. Researchers frequently report the difficulty to work in speech processing area without large enough databases. Also, with this database available, results can be compared in a statistically significant way.

Most of the applications of speech technology were contemplated, and further ones can be added along the time. Furthermore, the recording process can continue throughout, and the database can be in continuous expansion.

For the future, it is intended to build a telephone quality speech corpora by passing this database through a telephone line.

A SOFTWARE FOR VQ TEACHING

Amarildo Martins de Mattos[1] *and Carlos Alberto Ynoguti*[2]

Abstract *— This article reports a Matlab® script developed to help students to understand the basic concepts of vector quantization (VQ). It shows in a very intuitive way to design and build a simple two-dimensional vector quantizer. Its graphic interface allows a quick understanding of all the phenomena involved in the quantization process. In addiction, the software makes a comparison between the exhaustive search and a tree-based search to show that the last one has a much better performance.*

Index Terms — Vector quantization, block quantization, source coding.

INTRODUCTION

Quantization and sampling are the basic steps to use the digital technology with analog signals. For unidimensional signals like voice or audio there is the class of scalar quantizers which are exhaustively studied [2] and there are several softwares for their simulation.

Vector quantization can be viewed as a generalization of scalar quantization to the quantization of a vector, an ordered set of real numbers. The jump from one dimension to multiple dimensions is a major step and allows a wealth of new ideas, concepts, techniques and applications to arise that often have no counterpart in the simple case of scalar quantization. While scalar quantization is used primarily for analog-to-digital conversion, VQ is used with sophisticated digital signal processing, where in most cases the input signal already has some form of digital representation and the desired output is a compressed version of the original signal.

VQ is usually, but not exclusively, used for the purpose of data compression. Nevertheless, there are interesting parallels with scalar quantization and many of the structural models and analytical and design techniques used in VQ are natural generalizations of the scalar case.

A vector can be used to describe almost any type of pattern such as a segment of a speech waveform or of an image, simply by forming a vector of samples from the waveform or image. Another example, of importance in speech processing, arises when a set of parameters (forming a vector) is used to represent the spectral envelope of a speech sound. Vector quantization can be viewed as a form of pattern recognition where an input pattern is approximated by one of a predetermined set of standard patterns, or in other words, the input pattern is matched with one of a stored set of templates or codewords.

Vector quantization can also be viewed as a front end to a variety of complicated signal processing tasks, including classification and linear transforming. In such applications, VQ can be viewed as a complexity reducing technique because the reduction in bits can simplify the subsequent computations, sometimes permitting complicated digital signal processing to be replaced by simple table lookups.

Thus VQ is far more than a formal generalization of scalar quantization. In the last years it has become an important technique in speech recognition as well as in speech and image compression, and its importance and application are growing.

In this article, a brief explanation of the basic principles and design methods are provided. In the sequel, a Matlab implementation of a vector quantizer is described.

VECTOR QUANTIZATION

An *N*-level *k*-dimensional quantizer is a mapping q that assigns to each input vector $\mathbf{x} = (x_0, \ldots, x_{k-1})$, a reproduction vector $\hat{\mathbf{x}} = q(\mathbf{x})$ drawn from a finite reproduction alphabet, $\hat{A} = \{\mathbf{y}_i; i = 1,\ldots,N\}$. The quantizer is completely described by the reproduction alphabet (or codebook) $\hat{A}$, together with the partition $S = \{S_i, i = 1,\ldots,N\}$, of the input vector space into the sets $S_i = \{\mathbf{x} : q(\mathbf{x}) = \mathbf{y}_i\}$ of input vectors mapping into de i^{th} reproduction vector (or codeword). Such quantizers are also called block quantizers, vector quantizers, and block source codes.

Distortion measures

We assume the distortion caused by reproducing an input vector $\mathbf{x}$ by a reproduction vector $\hat{\mathbf{x}}$ is given by a nonnegative distortion measure $d(\mathbf{x}, \hat{\mathbf{x}})$. Many such distortion measures have been proposed in the literature, and for the sake of simplicity, we'll use the squared error distortion or Euclidean distance in this work. This distortion is given by

$$d(\mathbf{x}, \hat{\mathbf{x}}) = \sum_{i=0}^{k-1} |x_i - \hat{x}_i|^2 \quad (1)$$

[1] Amarildo Martins de Mattos, INATEL National Institute of Telecommunications, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, amartins@inatel.br
[2] Carlos Alberto Ynoguti, INATEL National Institute of Telecommunications, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, ynoguti@inatel.br

Performance

Let $\mathbf{X} = (X_0, \ldots, X_{k-1})$ be a real random vector described by a cumulative distribution function $F_X(x)$. A performance measure of a quantizer q applied to the random vector **X** is given by the expected distortion

$$D(q) = E\left[d\left(\mathbf{X}, q(\mathbf{X})\right)\right] \tag{2}$$

where E denotes the expectation with respect to the distribution of **X**.

Of course, the lower $D(q)$ is, the better is the quantizer. So, an N-level quantizer is said to be optimal (or globally optimal) if it minimizes the expected distortion, that is, q^* is optimal if for all other quantizers having N reproduction vectors, $D(q^*) \leq D(q)$. A quantizer is said to be locally optimum if $D(q)$ is only a local minimum, that is, slight changes in q cause an increase in distortion.

The goal of block quantizer design is to obtain an optimal quantizer if possible and, if not so, to obtain a locally optimal and hopefully good quantizer. Several such algorithms have been proposed in the literature, and in this article we will discuss the most popular of them, due to Linde, Buzo and Gray [3], commonly referred as the LBG algorithm. The LBG algorithm is based on the Lloyd's Method I [4], which will described next.

VQ DESIGN

The Loyd's method

The Loyd's Method I is based on the solution of the two following problems:

- Given a quantizer q, described by a reproduction alphabet $\hat{\mathbf{A}} = \{\mathbf{y}_i, i = 1, \ldots, N\}$, what is the optimum partition $S = \{S_i, i = 1, \ldots, N\}$?
- Given a partition $S = \{S_i, i = 1, \ldots, N\}$, where the code words must be placed so that $D(q)$ is minimized?

The solutions for the two problems are:

- A partition that is optimum for $\hat{\mathbf{A}}$ is easily constructed by mapping each input vector **x** into the codevector $\mathbf{y_i}$ that minimizes the distortion $d(\mathbf{x}, \mathbf{y_i})$, that is, by choosing the minimum distortion or nearest-neighbor codeword for each input.
- For a given partition S, the best location for each codeword is the centroid or center of gravity of each set S_i.

The LBG algorithm

The LBG algorithm builds up the vector quantizer by solving these two problems in a recursive way. The LBG algorithm can be state as follows:

The LBG algorithm

- **Initialization:** Choose an arbitrary set of K code vectors, say $\bar{\mathbf{x}}_k, k = 1, 2, \ldots, K$.
- **Recursion:**
  1. For each feature vector **x** in the training set, "quantize" **x** into code vector $\bar{\mathbf{x}}_{k^*}$, where

$$k^* = \arg\min_k d\left(\mathbf{x}, \bar{\mathbf{x}}_{k^*}\right) \tag{3}$$

  Here $d(\cdot,\cdot)$ represents some distortion measure in the feature space. In this work, the Euclidean distance, (1) was used.

  2. Compute the total distortion that has occurred as a result of this quantization,

$$D = \sum d\left(\mathbf{x}, q(\mathbf{x})\right) \tag{4}$$

  where the sum is taken over all vectors **x** in the training set, and $q(\mathbf{x})$ indicates the codeword to which **x** is assigned in the current iteration. If D is sufficiently small, STOP.

  3. For each k, compute the centroid of all vectors **x** such that $\bar{\mathbf{x}}_k = q(\mathbf{x})$ during the present iteration. Let this new set of centroids comprise the new codebook, and return to Step 1.

There also exists a slight variation on the LBG method, which differs in the way the algorithm is initialized: the number of clusters is iteratively built up o a desired number (power of two) by "splitting" the existing codewords at each step and using these split codes to seed the next iteration. This modified algorithm is shown below:

Initial guess by splitting

- **Initialization:** find the centroid of the entire population of vectors. Let this be the (only) initial codevector.
- **Recursion:** There are a total of I iterations, where 2^I codevectors are desired. Let the iterations be i = 1, 2, …, I. For iteration i,
  1. "Split" any existing code vector, say $\bar{\mathbf{x}}$, into two code vectors, say $\bar{\mathbf{x}}(1+\varepsilon)$ and $\bar{\mathbf{x}}(1-\varepsilon)$, where ε is a small number, typically 0.01. This results in 2^i new code vectors, say $\bar{\mathbf{x}}_k^i, k = 1, 2, \ldots, 2^i$
  2. For each feature vector **x** in the training set, "quantize" **x** into code vector $\bar{\mathbf{x}}_{k^*}$, where

$$k^* = \arg\min_k d\left(\mathbf{x}, \bar{\mathbf{x}}_{k^*}\right) \tag{5}$$

  Here $d(\cdot,\cdot)$ represents some distortion measure in the feature space. In this work, the Euclidean distance, (1) was used.

3. For each k, compute the centroid of all vectors $\mathbf{x}$ such that $\overline{\mathbf{x}}_k^i = q(\mathbf{x})$ during the present iteration. Let this new set of centroids comprise the new codebook and, if $i < I$, return to Step 1.

VECTOR QUANTIZATION

Once the vector quantizer is constructed, it's ready for use. There are several ways to perform vector quantization of a input vector, and here two of them will be discussed in details: the exhaustive search and the tree search.

Exhaustive search

The exhaustive search is the most direct and simple encoding algorithm. For this encoding scheme, a codevector is selected by calculating the distortion between the input vector x and all the codevectors in the codebook. The codevector having the minimum distortion is then selected.

Tree search

The exhaustive search outline above requires, for a codebook of size N, N distortion evaluations to be performed. For the squared error distortion measure, it means that k multiplications and (k-1) additions must be performed for each of the N codevectors. Other distortion measures may have much higher computational demands. Frequently the codebook size needed in applications is very large. Furthermore, the vector rate $\boldsymbol{f}_v$ is rather high in typical communications systems and the number of distortion calculations that must be performed per unit time, given by $N\boldsymbol{f}_v$, implies a very demanding computational complexity, typically involving many millions of arithmetic operations per second.

These considerations motivated serious study of more efficient algorithms that yield the nearest codevector without requiring an exhaustive search through the codebook. Several approaches have been proposed, and here, the tree search algorithm will be presented.

Consider the two-dimensional quantizer shown in Figure 1. In this Figure, the six code vectors are indicated with dots and the labeled "hyperplane" decision boundaries (line segments) are indicated with thick lines, which separate neighbor regions. Thin lines indicate extensions of the hyperplane segments to help visualize the efficient coding operation. Each decision boundary is a segment of a hyperplane and is labeled with the letters A, B, C, … and the two half spaces separated by each hyperplane are labeled '+' and '-'. Next, a tree structure for an efficient successive approximation procedure to locate an input vector will be described.

Suppose the initial step of a search algorithm is to compute the binary decision function for the hyperplane A. If the input $\mathbf{x}$ is on the right side of A (labeled '+'), then code vectors 1 and 5 are immediately eliminated as candidates for the nearest neighbor, since they are contained entirely on the left side of A. Similarly, code vectors 2 and 3 are eliminated as candidates if the input is on the left side of A ('-'). Depending on the result of the first test, we choose one of two new tests to perform. Thus if the input lies on the '+' side of A, we then test to see on which side of the hyperplane C it lies. If the input is on the '-' side of A, we then determine of which side of hyperplane B it lies. Each test eliminates one or more candidate codewords from consideration. This kind of procedure corresponds to a tree structure for the search algorithm as shown in Figure 2.

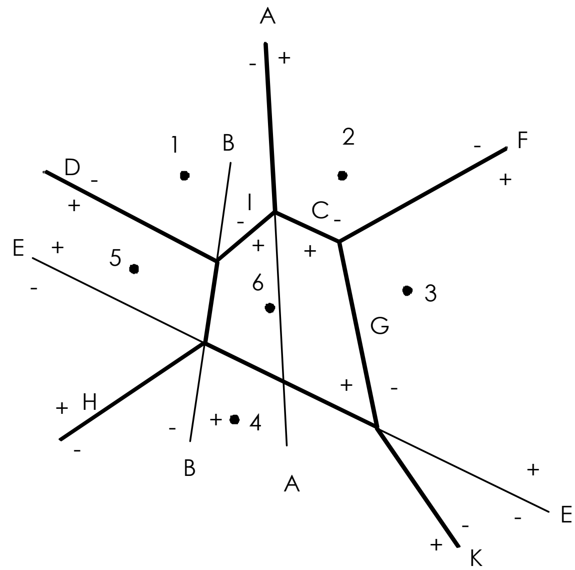

FIGURE 1
A TWO-DIMENSIONAL VECTOR QUANTIZER. (AFTER GERSHO & GRAY [1]).

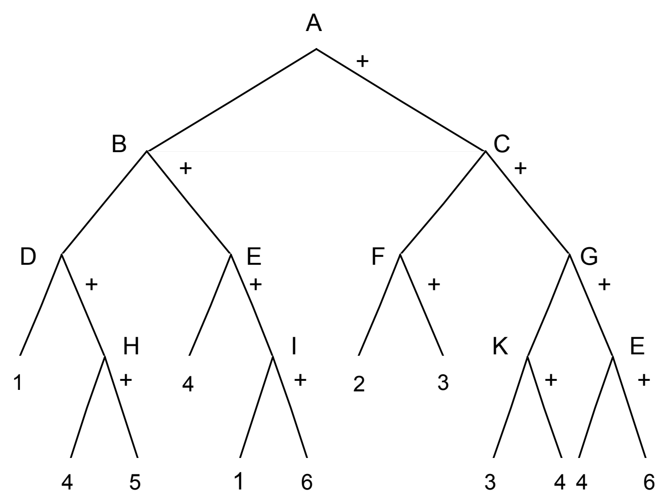

FIGURE 2
TREE STRUCTURE FOR EFFICIENT NEAREST NEIGHBOR SEARCH (AFTER GERSHO & GRAY [1]).

Note that this particular tree always leads to a final determination of the nearest neighbor code vector after at most 4 binary decisions. Hence, the search complexity has been reduced from 6 distance computations to 4 scalar product operations.

MATLAB SCRIPTS

To illustrate these concepts, three Matlab scripts were developed, one for codebooks design, and the others for search time evaluation. The first script implemented the modified LBG algorithm, the second the exhaustive search method, and the third, the tree search procedure. Next, the script outputs are shown.

VQ design

As an illustration of the VQ design using the LBG algorithm, let the training points be as shown in Figure 3.

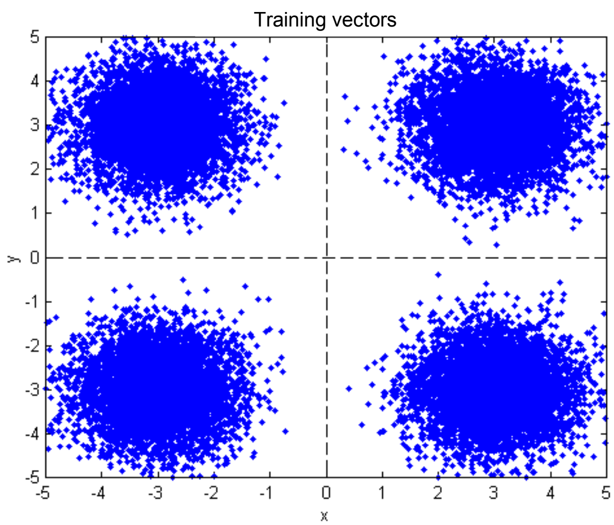

FIGURE 3
TRAINING VECTORS FOR THE VQ DESIGN.

If a codebook with 4 codevectors is desired, it's clear that these codevectors should be located at positions (-3,-3), (3,-3), (-3,3) and (3,3), as shown in Figure 4.

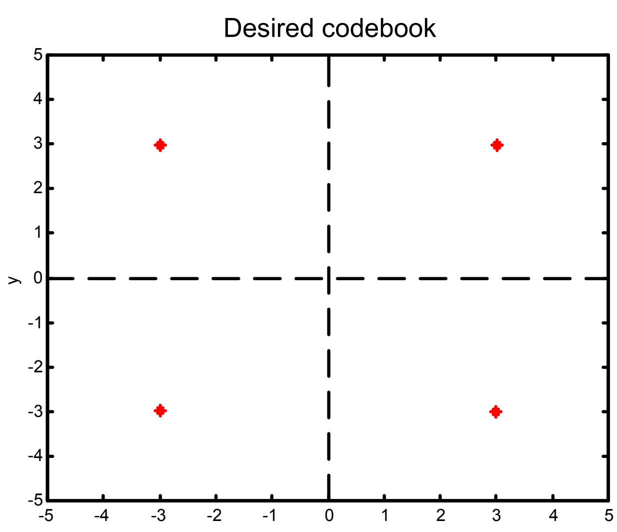

FIGURE 4
DESIRED 4 CODEVECTORS CODEBOOK.

In the first step, only one centroid is to be calculated, as the center of gravity of the entire set of training points. For the points given in Figure 3, these codevector sholud be located somewhere nearby the origin, and the output of the program is shown in Figure 5.

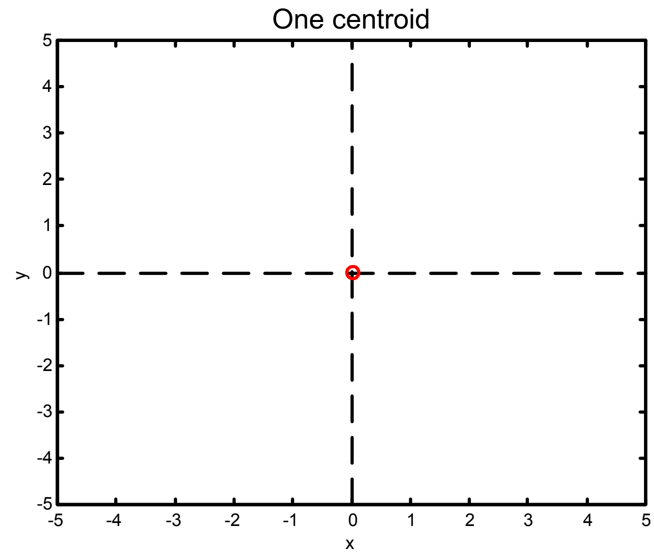

FIGURE 5
A ONE VECTOR CODEBOOK GENERATED BY THE PROGRAM.

Next, this unique codevector should be 'splitted', giving rise to two other ones. The result of the splitting procedure is shown in Figure 6.

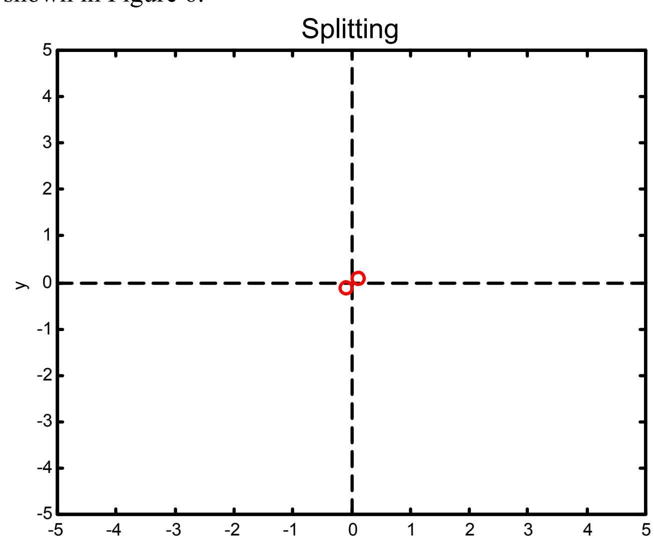

FIGURE 6
CODEBOOK AFTER SPLITTING.

The next step is to reallocate the codevectors so that a minimum distortion codebook is achieved. After a few iterations, the final codebook of order 2 is shown in Figure 7.

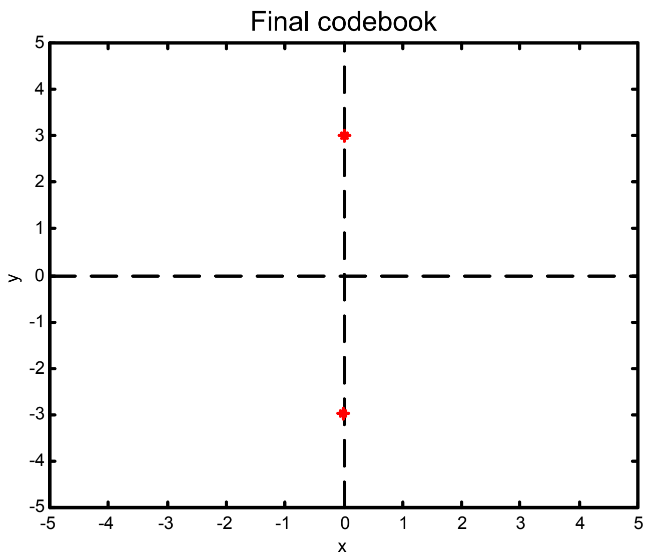

FIGURE 7
FINAL CODEBOOK OF ORDER 2.

Again, the splitting procedure is applied to both the codevectors of this codebook, yielding the configuration of Figure 8

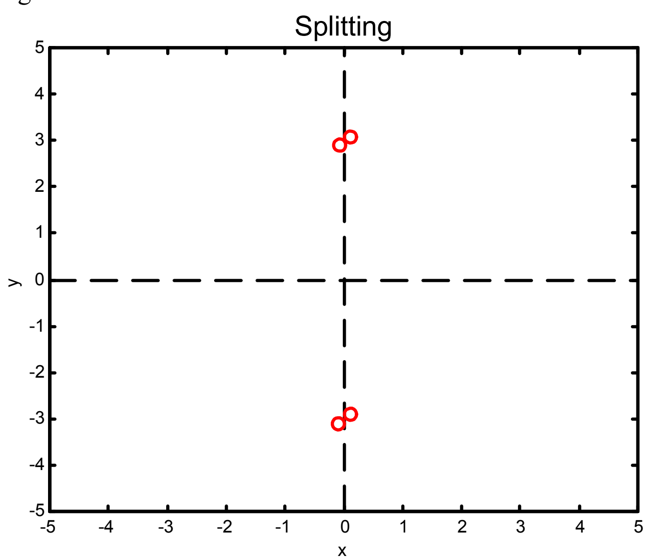

FIGURE 8
CODEBOOK OF ORDER 4 AFTER SPLITTING THE CODEVECTORS OF CODEBOOK OF ORDER 2.

After some iterations, the algorithm leads to the final codebook of Figure 4.

Quantization

After the design of the quantizer, it's time to analyze the quantization performance in terms of quantization time. For this purpose, 10000 points were generated according to a bidimensional uniform distribution, as shown in

The exhaustive search and tree search were then performed, and the quantization times were 1.047 s for the exhaustive search and 0.625 s for the tree search, showing the effectiveness of the later method.

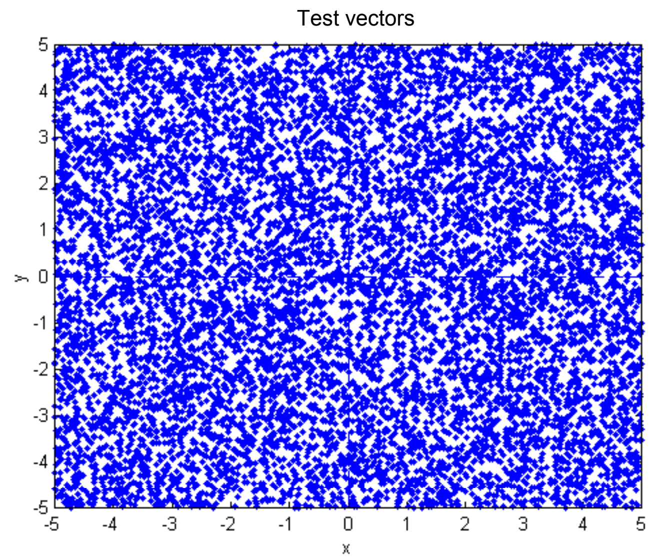

FIGURE 9
POINTS GENERATED FOR SEARCH PROCEDURES TESTS.

CONCLUSIONS

In this article a brief outline of vector quantization theory was presented, together with a Matlab® implementation of the LBG algorithm, the exhaustive search and the tree search, leading to a better comprehension of all phenomena involved.

Computational simulations are a very good way to teach because there are no 'tricks': the students can see the algorithm working and easily understand the concepts involved. As one said: 'A picture say more than a thousand of words'.

For the future, a better user interface is being planned, maybe using the Graphic User Interface provided with Matlab®.

CONTINUOUS ON-LINE EVALUATION OF STUDENT SEMESTRAL ACTIVITY

Vladimir G. Zakharov[1]

Abstract *— An attempt is made to assess activities of a student during his academic semester in a Technical University. Lectures, seminars, laboratory works, home-work are typical activities of any student. The mark received for a semestral exam serves as the criterion to judge about student's knowledge. However, this mark very often does not reflect the real state of things. In order to make the evaluation trustworthy a quantitative approach is necessary to estimate the student activity during the whole semester. The evaluation proposed is based on a continuous assessment of results achieved by each student of a group. A feature of this method is using computers to provide each student with his individual tasks for home-work and giving him a chance to check up himself. Physics is taken as a test subject but the whole approach can be generalized for any fundamental or applied engineering discipline in a Technical University.*

Index Terms — Assessment of knowledge, Computer based examination, Home-work, Individual tasks,

INTRODUCTION

The paper appeals to one of most important problems throughout Russia and elsewhere. This is the problem of students knowledge evaluation in the context of teaching fundamental and engineering disciplines in Technical Universities [1]-[4].

In Russian higher school the four grade system of evaluation is generally accepted: "unsatisfactory", "satisfactory", "good" and "excellent" (corresponding to marks in Russian secondary school system from "2" to "5" respectively). If a discipline is taught in a University, say, during three semesters the mark for the final examination is then transferred to the "diploma annex" which is the supplement to the diploma containing the list of major subjects dominated by a graduate with corresponding marks.

Unfortunately, there is no guarantee that this mark adequately reflects the level of knowledge in a given field of science. Taking into account that the number of students in an academic group (class) of a typical Russian University is about 25 and that the number of groups attending lectures of Professor *X* is 4-6 one can imagine that the mark given by Professor *X* to Student *Y* depends upon many aspects other than academic ones:

- Psychical state of Student *Y* and the state of his health;
- Professor's individual peculiarities and habits;
- Professor's personal attitude to Student's appearance (in case of oral exams which are very common in Russia);
- General reputation of a given academic group undergoing the exam;
- Number of days between two consequent exams (Normally there are two examination sessions in Russia - in January and in June. Each consists of 5-6 strictly scheduled exams with short intervals between them).

It is also clear that Professor *X* who has 100 -150 students attending his lectures is physically unable to know personally each of them.

The situation is better with Assistant Professors who conduct seminars and laboratory works in a particular group. They have a direct constant contact with students and know their potential and their attitude to studies. However, at exams they play but auxiliary role and are not responsible for the final mark given by the lecturer – Professor *X*.

The purpose of the present paper is to highlight a student's advance during the semester by setting the quantitative assessment of his overall activity. This assessment could be expressed as a mark in any conventional mark system accepted in Russia or elsewhere and taken into account by the lecturer when he gives his final mark for the exam.

SETTING THE QUANTITATIVE SYSTEM OF ASSESSMENT

The following kinds of student academic activity undergo the quantitative assessment:

- Lectures,
- Home-work,
- Seminars (Practicals),
- Laboratory works.

These four activities are four principal components which serve as a basis for the future consequent assessment of activity for each student of any group.

At the end of semester a mark will be set for each of these activities and finally the resultant average is to be derived. This average mark should embrace the whole semestral activity of a student and strongly influence the examination mark at his final exam.

[1] Vladimir Gennadievich Zakharov, Ph.D., ING PAED IGIP, Moscow State Automobile and Roads Institute (MADI Technical University), Leningradski prospekt, 64, Moscow 125829, Russia, zakharov@crdf.ru

Let us consider separately all above mentioned kinds of student activity and ways to set the semestral mark.

Lectures

The topics of the syllabus within a semester represent separate units (or modules) of the subject lectured. They should be duly controlled by the lecturer as soon as any of these units is over.

Conservation of Momentum and Energy

1). Two little balls with masses m_1 and m_2 moving uniformly in the same direction with velocities $\boldsymbol{V_1}$ and $\boldsymbol{V_2}$ so that $V_2 > V_1$. Consider their absolutely elastic collision. The resultant heat irradiated due to collision will be equal to

A. Zero.

B. $\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2}$.

C. $\sqrt{(m_1 v_1)^2 + (m_2 v_2)^2}$.

D. $m_1 v_1 + m_2 v_2$.

2). The magnitude of their resultant momentum is equal to

A. Zero

B. $m_1 v_1 + m_2 v_2$.

C. $m_1 v_1 - m_2 v_2$.

D. $\sqrt{(m_1 v_1)^2 + (m_2 v_2)^2}$.

3). Consider now their inelastic collision. The resultant heat irradiated is equal to:

A. $\frac{m_1}{m_1 + m_2} \left(\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2} \right)$

B. Zero.

C. $\frac{m_1 v_1^2}{2} + \frac{m_2 v_2^2}{2}$.

D. $\sqrt{(m_1 v_1)^2 + (m_2 v_2)^2}$.

4). The balls are now moving towards each other in perpendicular directions. The magnitude of their resultant momentum is equal to

A. $m_1 v_1 + m_2 v_2$.

B. $\sqrt{(m_1 v_1)^2 + (m_2 v_2)^2}$.

C. $m_1 v_1 - m_2 v_2$.

D. Zero.

5). A ball falls from the height *h* onto a flat massive plate and suffers the absolutely elastic collision with its surface. What does the total energy of the balls converts into during the interaction with the plate?

A. Into heat

B. Into potential energy *mgh*.

C. Into potential energy of elastic interaction.

D. Into kinetic energy of the resultant motion

FIGURE. 1
EXAMPLE OF A LECTURE TEST

The control can be realized at the end of each unit as a written test containing theoretical questions with multiple-choice answers. If a classroom where the lectures are delivered is equipped with computer technique the whole procedure can be computerized. The questions suggested by the professor should not imply long and boring written answers. They should be easy but appeal to profound understanding by pupils of theoretical backgrounds of a law or phenomenon considered in the topic tested. A set of questions for one student should be compiled in a way that the divergence in the evaluation should be the least possible. An example of test *Conservation of Momentum and Energy* is presented on Figure 1.

The test is intended for *multiple-choise answer* system and five correct answers (*A, B, A, B, C)* make the mark 5 (excellent). Not less than 5-6 tests should be realized during the semester and the average mark calculated.

Home-work

Home-work is considered as a very important component of the whole academic process. It should always be thoroughly prepared beforehand and duly checked. The tasks of home-work should be compiled on the *individual* basis. When a home- task is the same for the whole group it often loses its value because weak students have a habit to copy the ready solutions from exercise books of strong and honest students (at least in Russia this is a common problem). Any system which allows preparing sets of *individual* tasks will give good results. It is worth suggesting one of them.

Individual Task System (ITS). The individual student work has its enormous effect only if it is being guided and controlled by professor. Home-work as a part of ITS plays an extremely important role here and it is useful only when the problems of any home-work are compiled correctly from the methodical point of view and the individual capacities and particularities of a given student are taken into account. That is the problem - not for the student but for his teacher! And the more number of students in a class the heavier is this problem. 25-30 pupils in a class is normal for an average Russian Technical University and when a home-work (consisting of 5-6 problems from a text-book) is the same for the whole class the copying from somebody's exercise-book becomes inevitable (or even very popular). Every Russian teacher is well acquainted with this sad reality which complicates his an adequate assessment of a student activity and often makes a wrong opinion about student's personality. In order to make the assessment objective and trustworthy the ITS has been elaborated. Let us consider the basic principles of the ITS.

The ITS is realized using a PC loaded with a special program designed by the author written in *C* or C^{+} programming language which makes the whole system compact and allows to introduce any desirable changes in the easiest way.

A collection of problems and questions on Physics (or another subject) constitutes a subsystem of files called '*Bank Files'* which serves as a source of tasks to be issued for students. These files are always 'under construction': old problems can be removed, modified, corrected or substituted for new ones.

'Bank Files' itself is divided into several separate files containing problems on different chapters of the discipline. For Physics they are: *Mechanics, Molecular Physics, Electricity, Magnetism, Oscillations, Structure of Matter* etc. It is, therefore, a system of electronic files containing a collection of problems and questions which are used to compile tests, examination papers, home-works etc. If printed out it looks like a familiar book of problems with one exception: one of necessary numerical parameters in each problem is replaced by *S*. This *S* - parameter is a variable quantity which will be substituted for a number when a task is printed out for a student for his home-work or test. Its numerical value will be different even if the given problem is used twice in a class, i.e. for two students of the same group. Consequently, these two problems will have different answers. Figure 2 presents a fragment of the sub-file '*Mechanics'*. Five lines are reserved for each problem or question. The first line is never printed out and reserved for internal use by professor. It contains the number of a problem in the file, level of complexity, branch of the topic (kinematics, dynamics etc.) and another information.

#34-------*Conservation of Energy*—CmplxLevel: 3---
A sand bag of mass 10 *kg* is suspended with a 3 *m* long weightless string. A bullet of mass *S g* is fired with a speed 20 *m/s* into the bag. Calculate the energy converted to heat in the collision.
#35-------*Angular Momentum*-----CmplxLevel: 2-----
A wheel is rotating with an angular speed Ω = *S rad/s*on a shaf. A second identical wheel, initially at rest, is suddenly coupled to the same shaft What is the angular speed of the resultant system?
#36------*Dynamics of Particle*------CmplxLevel:4-----
A force *F* = 50 *N* is acted upon a particle whose

FIGURE. 2
FRAGMENT OF BANK FILE 'MECHANICS'

Two main sub-programs called TASK and ANSWER constitute the body of the ITS. Both programs are linked with the file VARIANT as shown on Figure 3.

File VARIANT consists of electronic matrices filled by professor with numbers of problems from *Bank Files*. Each row of any matrix corresponds to a student of the group and each column corresponds to a particular problem in the given task. Each matrix corresponds to a set of individual tasks on a given topic (e.g. Topic 1: *Kinematics*, Topic 2: *Dynamics* etc.). Consequently, sets of VARIANT are filled by professor gradually one by one.

When the program TASK is launched by professor, the number of set and the title of topic are entered by him. In the course of program realization reading of problem numbers and a consequent printing out of the corresponding problem takes place to compose a complete task of 5-6 problems to each student.

As it was mentioned above any problem contains one *S*-parameter to be replaced by a suitable numerical quantity. Replacing of this *S*–parameter is realized by means of a subroutine which substitutes the reasonable value of the

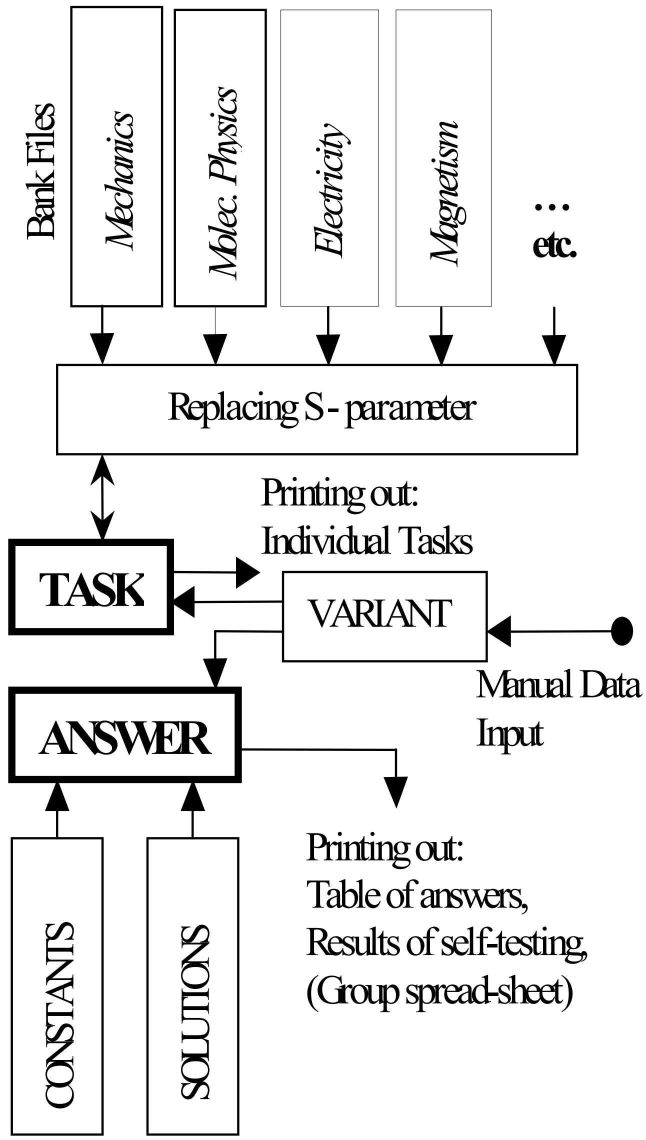

FIGURE. 3
GENERAL STRUCTURE OF THE ITS

corresponding numerical parameter. When a problem is placed several times in different places of the same set the answers will be all different.

Once printing of a given set of individual tasks is finished the program ANSWER will then be launched by professor to print *Table of Answers* to the set. ANSWER reads problem numbers and one by one calculates the numerical answers taking the general formulas from the subroutine SOLUTIONS and replacing there *S*-parameters by the numerical values.

Another function of the ANSWER is to realize *self-testing regime* which is very popular among students. This regime gives an immediate overall assessment of the whole group's activity.

The schedule for the self-testing session for a group is determined by professor. Normally, a week or two are given to let students solve the problems of the current set. Then the professor gathers students in a computer class-room where the program ANSWER is launched by him in self-testing dialogue regime. On PC's request, the *name*, *number of set*, and *number of task* are entered by each student at his PC. Then the PC requests to enter the answer of Problem 1. Once the answer is entered the PC compares it with that immediately calculated and gives out its verdict: YES or NO. The ANSWER's numerical solution in the case 'YES' may slightly differ from the result received and entered by a student. The permissible error in student's calculations is defined by the percentage (normally 5-7%) set by the professor. The options of ANSWER allow adjusting this value. As soon as the answer for the last problem is entered the session is over. The mark for the whole set is monitored on the student's display. Simultaneously, the overall spread-sheet of results (Figure 4) is being compiled on professor's display and can easily be printed out as a hard copy for his reference.

Set 3: CONSERVATION LAWS							
Task #	Name	Problems					Mark
		1	2	3	4	5	
1	Zakharov V.	Y	Y	N	Y	Y	4
2	Ivanov G.	Y	Y	Y	Y	Y	5
3	Schneider U.	N	N	N	Y	Y	2

FIGURE. 4
SPREAD-SHEET OF RESULTS

The mark not necessarily corresponds to the exact number of solved problems. There might be used other criteria which take into account the total number of problems suggested in the task, the level of complexity etc.

These spread-sheets collected by professor at a series of such sessions give him a complete picture of the state of things in the group. Namely, it enables:

- to estimate the general level of understanding of the subject (Physics, Mathematics, Civil Engineering etc.) in its practical aspect;
- to find out the most difficult for understanding topics and pay them more attention in the future;
- to let students realize themselves in their individual creative work;
- to teach students of correcting mistakes in a very productive 'Professor - Student' dialogue.

When analyzing the general results of a session the professor takes his decision to give a chance for a student to improve his results. He may easily compile (within a few minutes) a new task for U. Schneider (see Figure 4) making a particular accent on problems 1, 2 and 3 selecting carefully problems of this type for his new task.

The average mark obtained by a student for all the sessions is automatically calculated as soon as all the sessions are over. This mark is the criterion of a student's individual semestral activity at home-works.

Seminars (Practicals)

This kind of work with students gives more opportunities since it is here where a student cam demonstrate his abilities to solve the concrete problems. A seminar is normally conducted by Assistant Professor and begins with a brief excursion to theory recently delivered by the lecturer. It is necessary to underline that the seminar should never *substitute* the lecture but *support* it. Unlike traditions of the western school it is common in Russia to call a student and ask him to solve a problem (selected by professor) publicly. The author of the present paper heard many words of reproach and dissatisfaction both from students and colleagues when he experienced his teaching in Zambia and Mozambique but nobody could make him believe that this procedure was a human rights violation and normal exams (recognized by all western world) were not. It is shown by experience that it is not difficult to convince students that such a procedure is absolutely necessary. Indeed, not only professor benefits from it but student himself learns a science how to behave himself and make presentations in front of a large audience. (This is the science worth learning!)

The quantitative evaluation of activity at the seminars is made using the technique considered in details in the previous chapter. Three or four tests are compiled by the professor in the course of a semester. They are examined by the professor. Now he checks up not only answers but also the way of solving the problems. He makes his written remarks and observations in a rather 'conservative' traditional manner which can also be very useful in spite of technical progress benefits. Each set of these tests in comparison with those for home-works is more complicated. If student sessions for self-control of home-works can be compared with goods of mass consumption, the test for seminars is a 'hand-work'. As previously the average mark is derived for the whole semester.

Laboratory Works

The work in laboratories is considered by the author as very important. A laboratory is the place where all experimental and cognitive skills of a student can be realized and (what is very essential) developed.

It is needless to outline that the equipment of any student laboratory should be adequate and up-to-date. The old devices and instruments can be extremely useful for lecture demonstrations where simplicity of old instruments gives an explicit treatment of their action and lets the students penetrate into the history of science discoveries. Once a certain physical phenomenon or a law is understood by a student at lectures, some modern conventional instruments can be demonstrated by lecturer and later used at laboratory sessions [5,6]. It is the laboratory that should teach a student how to use them.

Each laboratory session normally takes place once a week and lasts 2 *academic hours* (1 academic hour = 45 min. in Russia). Eight (out of 16) sessions of a semester are intended for work performing (experimental sessions), and eight are 'to defend' the work (theoretical sessions). Each theoretical session follows the experimental one. Each work is carried out by a brigade of two students and they defend their work together. Two assistant professors are usually engaged into conducting of the whole session. A schedule of works should give the students the complete information (*what* and *when*). The works should be clearly described in special guide-books. The following points then undergo the evaluation:

- Readiness of a student to carry out his scheduled laboratory work;
- The experimental skills developed by student in the course of work;
- Understanding of theoretical backgrounds of the work performed.

The first point is realized at the beginning of a session as a free talk the professors have with every student of a group. The talk does not imply any deep understanding by students of a phenomenon underlying a given work. At this level the students must merely be acquainted with what they are supposed to do. Beforehand, they should have read the description of their scheduled work and know what to switch and what to turn. This is a rather friendly talk with the professor to get some hints and recommendations. A student's work-log should be filled with some relevant notes (formulas, brief descriptions of the experimental set-up etc.). Nevertheless, students must demonstrate someunderstanding and concern. If there is none his access to the work may be cancelled or postponed.

If a student receives professor's approval he gets the access to work and begins the experiment in accordance with the guide-book for laboratory works. At the end of the experimental session every student receives from professor a slip of paper with questions. This task is similar to those described above and compiled by professor using TASK sub-program of the ITS. The difference is that such slips do not contain numerical problems. They contain questions only – also taken from *'Bank Files'*. These questions are about theory and about methodics of the experiment as well. The real discussion with the students during the coming theoretical session is not limited to these printed tasks. Profound understanding and good experimental skills are supposed to be demonstrated by a student to get a high mark.

The results of measurements obtained during the experimental session are signed by the professor. The later data processing is carried out by students at home and presented at the following theoretical session together with answers to the questions formulated in their printed tasks. The average mark for the overall activity in the laboratory is derived at the end of the semester.

OVERALL EVALUATION

At the end of a semester the four average marks for four principle components of student activity will be available. Together with the examination mark they are supposed to give the full and objective picture of student's image.

These marks are extremely important and in many cases they are even more important that the marks received at the exams. Those are the functions of many random parameters of the examination day and can hardly present the real situation.

However, marks received in the course of the semester characterize a daily student work and reflect the state of things in a more adequate way. A correct quantitative evaluation of student's day-to-day progress helps a professor to form a correct approach and a right informal attitude to every student.

ACKNOWLEDGMENT

Author has the pleasure to express his cordial gratitude to Prof. Claudio da Rocha Brito, General Chair of ICECE'2003 and to all organizers of this event for their invitation to participate as a speaker and as a member of the International Advisory Committee.

Gaussian Mixture Models and Relaxation Labeling for Online Evaluation of Training in Virtual Reality Simulators

Ronei Marcos de Moraes[1] and Liliane dos Santos Machado[2]

Abstract — *Several approaches for evaluation of online or offline training in simulators based on virtual reality have been proposed. However great part of these approaches has a high complexity and it demands large computational structure, what is very expensive. An online evaluator must have low complexity algorithm to do not compromise the performance of simulator. We propose a new approach to online evaluation of training in simulators based on virtual reality. This approach uses Gaussian Mixture Models and Relaxation Labeling (GMM-RL) for modeling and classification of the simulation in pre-defined classes of training. This method provides the use of continuous variables without lost of information. So, it solves the problem of low complexity in online evaluators without compromise performance of the simulator and with good evaluation accuracy. Systems based on this approach can be applied in virtual reality simulators for training in several areas.*

Index Terms — *Gaussian Mixture Models, Relaxation Labeling, Training Evaluation, Virtual Reality.*

INTRODUCTION

The existence of an online evaluation tool in simulation system based on virtual reality is important to allow the learning improvement and users evaluation. Recently, new methods of evaluation for online training in virtual reality simulator have been proposed [5, 7, 11, 13, 14, 18, 19].

In medicine, some models for offline or online evaluation of training have been proposed. However, great part of these approaches depends of large computational structure, which is very expensive to be available in some Medical Centers in Brazil and several other countries.

Simulators bases on virtual reality (VR) for training need high-end computers to provide realistic haptics, stereoscopic visualization of 3D models and textures. Online evaluators must have low complexity to do not compromise performance of simulations, but they must have high accuracy to do not compromise evaluation. The Gaussian Mixture Models (GMM) can be a good option to do an online evaluation, because they can obtain good accuracy models and they are simple too. However, according to Tran et al. [22] Relaxation Labeling methods offer best performances for classification problems. In their paper, they used Gaussian Mixture Models followed by Relaxation Labeling for speaker recognition with better performance over Gaussian Mixture Models only. We propose the use of the methodology designed by Tran et al. [22] to improve performance of Gaussian Mixture Models for an online training evaluator in virtual reality simulators.

VIRTUAL REALITY AND SIMULATED TRAINING

Virtual Reality refers to real-time systems modeled by computer graphics that allow user interaction and movements with three or more degrees of freedom [24]. More than a technology, virtual reality became a new science that joins several fields as computers, robotics, graphics, engineering and cognition. Virtual Reality Worlds are 3D environments created by computer graphics techniques where one or more users are immersed totally or partially to interact with virtual elements. The quality of the user experience in a virtual reality world is given by the graphics resolution and by the use of special devices for interaction. Basically, the devices stimulate the human senses as vision, audition and touch: head-mounted displays (HMD) or even conventional monitors combined with shutter glasses can provide stereoscopic visualization; multiple sound sources positioned provides 3D sound; and touch can be simulated by the use of haptic devices [16,8].

There are many purposes for virtual reality systems, but a very important one is the simulation of procedures for training. Virtual reality systems for training provide significant benefits over other methods, mainly in critical procedures. One example of training based on VR systems is the flight simulators used for the pilots' training in the civil aviation [23]. In medicine, the use of virtual reality systems for training is beneficial in cases where a mistake could result in physical or emotional impact on patients. Systems for different modalities in medicine have been developed, as training in: laparoscopy [25], prostate examination [1], ocular surgery [9] and bone marrow harvest [6]. In some cases, the procedures are done without visualization for the physician, and the only information he receives is done by the tactile sensations provided by a robotic device with force feedback. These devices can measure forces and torque applied during the interaction [10] and these data can be used in an evaluation [5,18].

EVALUATION IN VIRTUAL REALITY SIMULATORS

The evaluation of simulations is necessary to assess the training quality and provide some feedback about the user performance. User movements, as spatial movements, can be collected from mouse, keyboard and any other tracking device. Applied forces, angles, position and torque can be collected from haptic devices [21]. So, virtual reality systems can use one or more variables, as the mentioned above, to evaluate a simulation performed by user.

Some simulators for training have a method of evaluation. However they just compare the final result with the expected one or are videotape records post-analyzed by an expert [1]. Recently, some models for offline or online evaluation of training have been proposed, some of them use Discrete Hidden Markov Models (DHMM) [18] or Continuous Hidden Markov Models (CHMM) [19] to modeling forces and torque during a simulated training in a porcine model. Machado et al. [5,7] proposed the use of a fuzzy rule-based system to online evaluation of training in virtual worlds. Moraes and Machado [13] proposed the use of CHMM for online evaluation in any virtual reality simulators. After that, the same authors proposed another approach for online evaluation learning using Fuzzy Hidden Markov Models (FHMM) [14]. Using an optoelectronic motion analysis and video records, McBeth et al. [11] acquired and compared postural and movement data of experts and residents in different contexts by use of distributions statistics.

We are proposing the use of Gaussian Mixture Models and Relaxation Labeling (GMM-RL) to provide an online evaluation for simulators or training systems based on virtual reality. To test the method proposed, we are using a bone marrow harvest simulator [6]. This simulator has as goal to training new doctors to execute the bone marrow harvest, one of the stages of the bone marrow transplant. The procedure is done blindly, performed without any visual feedback except the external view of the donor body and the physician needs to feel the skin and bone layers trespassed by the needle to find the bone marrow and then start the material aspiration. The simulator uses a robotic arm that operates with six degrees of freedom movements and force feedback to give to the user the tactile sensations felt during the penetration of the patient's body [12]. In the system the robotic arm simulates the needle used in the real procedure, and the virtual body visually represented has the tactile properties of the real tissues. The evaluation tool proposed should supervise the user movements during the puncture and should evaluate the training according to N possible classes of performance.

GAUSSIAN MIXTURE MODELS (GMM)

This section presents the Gaussian Mixture Models (GMM) method for training evaluation. Parameter estimation equations for training expert models are presented first. After, the GMM method for training classification is then described as a maximum likelihood classifier. We follow the Tran et al. [22] explanation about GMM algorithm and classification.

Let $X=\{x_1, x_2,...,x_T\}$ be a set of T vectors, where each one is a d-dimensional feature vector extracted by T different information at virtual space, obtained by the simulator. These information can be applied forces, angles, position and torque extracted at d different interval of time. Since the distribution of these vectors is unknown, it is approximately modeled by a mixture of Gaussian densities as the weighted sum of c component densities, given by the equation

$$p(x_t\,|\lambda_k) = \Sigma^{c}_{i=1}\; w_i\, N(x_t, \mu_i, \Sigma_i) \qquad (1)$$

where λ denotes a prototype consisting of a set of model parameters $\lambda=\{w_i, \mu_i, \Sigma_i\}$, w_i, $i=1,...,c$ are the mixture weights and $N(x_t, \mu_i, \Sigma_i)$ are the d-variate Gaussian component densities with mean vectors μ_i and covariance matrices Σ_i:

$$N(x_t, \mu_i, \Sigma_i)=exp\{-1/2\,\}(x_t - \mu_i)'\,\Sigma_i^{-1}\,(x_t - \mu_i)\}\,/\,(2\pi)^{d/2}\,|\Sigma_i\,|^{1/2} \qquad (2)$$

To train the GMM, these parameters are estimated such that they best match the distribution of the training vectors. The maximum likelihood estimation is widely used as a training method. For a sequence of training vectors X for a λ, the likelihood of the GMM is done by:

$$p(X|\lambda) = \Pi^{T}_{t=1}\; p(x_t\,|\lambda) \qquad (3)$$

The aim of maximum likelihood estimation is to find a new parameter model $\bar{\lambda}$ such that $p(X|\,\bar{\lambda})\geq p(X|\lambda)$. Since the expression in (3) is a nonlinear function of parameters in λ, its direct maximization is not possible. However, these parameters can be obtained iteratively using the Expectation--Maximization algorithm [2]. In this algorithm, we use an auxiliary function Q done by:

$$Q(\lambda,\, \bar{\lambda})=\Sigma^{T}_{t=1}\, \Sigma^{c}_{i=1}\, p(i|x_t, \lambda)\, log\, [\, w_i\, N(x_t,\, \bar{\mu}_i,\, \bar{\Sigma}_i)] \qquad (4)$$

where $p(i|x_t, \lambda)$ is the *a posteriori* probability for performance class i, $i=1,...,c$ and satisfies

$$p(i|x_t, \lambda) = [\, w_i\, N(x_t, \mu_i, \Sigma_i)]\,/\,\{\Sigma^{c}_{k=1}\; w_k\, N(x_t, \mu_k, \Sigma_k)\} \qquad (5)$$

The Expectation--Maximization algorithm is such that if $Q(\lambda,\, \bar{\lambda})\geq Q(\lambda,\lambda)$ then $p(X|\,\bar{\lambda})\geq p(X|\lambda)$ [17]. Setting derivatives of the Q function with respect to $\bar{\lambda}$ to zero, we found the following reestimation formulas:

$$\bar{w}_i = 1/T\, \Sigma^{T}_{t=1}\; p(i|x_t, \lambda) \qquad (6)$$

$$\bar{\mu}_i = \Sigma^{T}_{t=1}\, [\, p(i|x_t, \lambda)x_t\,]\,/\,[\Sigma^{T}_{t=1}\, [\, p(i|x_t, \lambda)] \qquad (7)$$

$$\bar{\Sigma}_i=\{\Sigma^T_{t=1} [p(i|x_t, \lambda)(x_t- \bar{\mu}_i) (x_t- \bar{\mu}_i)' \} / [\Sigma^T_{t=1} [p(i|x_t, \lambda)] \quad (8)$$

The algorithm for training the GMM is described as follows:

1. Generate the *a posteriori* probability $p(i|x_t, \lambda)$ at random satisfying (5);

2. Compute the mixture weight, the mean vector, and the covariance matrix following (6), (7) and (8);

3. Update the a posteriori probability $p(i|x_t, \lambda)$ according to (5) and compute the Q function using (4);

4. Stop if the increase in the value of the Q function at the current iteration, relative to the value of the Q function at the previous iteration is below a chosen threshold, otherwise go to step 2.

The GMM classification

To provide GMM classification, we need several classes of performance λ. So, let λ_k, $k=1,...,N$, denote models of N possible classes of performance. Given a feature vector sequence X, a classifier is designed to classify X into N classes of performance by using N discriminant functions $g_k(X)$, computing the similarities between the unknown X and each class of performance λ_k and selecting the class of performance λ_{k^*} if [22]:

$$k^* = \arg\max_{1\le k\le N} \; g_k(X) \quad (9)$$

In the minimum--error--rate classifier, the discriminant function is the *a posteriori* probability:

$$g_k(X)=p(\lambda_k|X) \quad (10)$$

We can use the Bayes' rule

$$p(\lambda_k|X) = [p(\lambda_k)\, p(X|\lambda_k)] / p(X) \quad (11)$$

and we can assume equal likelihood of all performances, i.e., $p(\lambda_k)=1/N$. Since $p(X)$ is the same for all performance models, the discriminant function in (10) is equivalent to the following [4]:

$$g_k(X)=p(X|\lambda_k) \quad (12)$$

Finally, using the log--likelihood, the decision rule used for class of performance identification is:

Select performance model k if*

$$k^* = \arg\max_{1\le k\le N} \; \Sigma^T_{t=1} \; p(x_t|\lambda_k) \quad (13)$$

where $p(x_t|\lambda_k)$ is given by (1) for each k, $k=1,...,N$.

RELAXATION LABELING

The Relaxation Labeling (RL) was introduced by Rosenfeld et al. [20] and it is an interactive approach to update probabilities of a previous classification. This methodology is successfully employed in image classification [3]. In this case, we will use RL after applied GMM classification. So, let be a set of objects $A = \{a_1,a_2,...,a_N\}$ and a set of labels $\Lambda=\{\lambda_1,\lambda_2,...,\lambda_N\}$. An initial probability is given to each object a_t having each label λ_k, which is denoted by $p_t(\lambda_k)$. These probabilities satisfy the following condition:

$$\Sigma^N_{k=1} \; p_t(\lambda_k) = 1, \text{ for all } a_t \in A \quad (14)$$

The RL updates the probabilities $p_t(\lambda_k)$ using a set of compatibility coefficients $r_{tt'}(\lambda_k, \lambda_l)$, where $r_{tt'}(\lambda_k, \lambda_l)$: $\Lambda\times\Lambda\rightarrow[-1,1]$, whose magnitude denotes the strength of compatibility. The meaning of these compatibility coefficients can be interpreted as [22]:

a) If $r_{tt'}(\lambda_k, \lambda_l) < 0$, then λ_k, λ_l are incompatible for a_t *and* $a_{t'}$;
b) If $r_{tt'}(\lambda_k, \lambda_l) = 0$, then λ_k, λ_l are independent for a_t *and* $a_{t'}$;
c) If $r_{tt'}(\lambda_k, \lambda_l) > 0$, then λ_k, λ_l are compatible for a_t *and* $a_{t'}$;

For computing coefficients, two possible methods employ the concepts of statistical correlation and mutual information. The two methods are based on those developed by Peleg and Rosenfeld [15]. The correlation-based estimate of the compatibility coefficients is defined as

$$r_{tt'}(\lambda_k)(\lambda_l) = \{\Sigma^T_{t=1} [p_t(\lambda_k)- p(\lambda_k)][p_{t'}(\lambda_l)- p(\lambda_l)]\}/\{\sigma(\lambda_k)\sigma(\lambda_l)\} \quad (16)$$

where $p_t(\lambda_l)$ is the probability of $a_{t'}$ having label λ_l and $a_{t'}$ are the neighbors of $a_{t'}$, $p(\lambda_l)$ is the mean of $p_t(\lambda_l)$ for all $a_{t'}$, and $\sigma(\lambda_l)$ is standard deviation of $p_t(\lambda_l)$. To alleviate the effect of dominance among labels, the modified coefficients are [22]:

$$r^*_{tt'}(\lambda_k)(\lambda_l) = [1- p(\lambda_k)]\, [1- p(\lambda_l)]\, r_{tt'}(\lambda_k)(\lambda_l) \quad (17)$$

and the mutual-information based estimate of compatibility coefficient is

$$r_{tt'}(\lambda_k)(\lambda_l) = \log \{T\, \Sigma^T_{t=1} p_t(\lambda_k)\, p_{t'}(\lambda_l)\} / \{\Sigma^T_{t=1} p_t(\lambda_k)\, p_{t'}(\lambda_l)\} \quad (18)$$

The compatibility coefficients in (18) must be scaled in the range [-1,1].

The updating factor for the estimate $p_t(\lambda_k)$ at m^th^ interaction is:

$$q_t^{(m)}(\lambda_k)= \Sigma^{T}_{t'=1}\ d_{tt'}\,[\Sigma^{N}_{l=1}\ r_{tt'}(\lambda_k)(\lambda_l)\, p_{t'}^{(m)}(\lambda_l)] \qquad (19)$$

where $d_{tt'}$ are the parameters that weight the contributions to a_t coming from its neighbors $a_{t'}$ and subject to

$$\Sigma^{T}_{t'=1}\ d_{tt'} = 1 \qquad (20)$$

The updated probability $p_t^{(m+1)}(\lambda_k)$ for object a_t is given by:

$$p_t^{(m+1)}(\lambda_k) = \{p_t^{(m)}(\lambda_k)[1+ q_t^{(m)}(\lambda_k)]\} \;/\; \{\Sigma^{N}_{k=1}\ p_t^{(m)}(\lambda_k)[1+ q_t^{(m)}(\lambda_k)]\} \qquad (21)$$

The RL algorithm can be outlined as follows:

1. Estimate the initial probabilities for each object satisfying (14)
2. Compute the compatibility coefficients using (17) or (18)
3. Calculate the updating factor defined in (19)
4. Update the probabilities for each object using the updating rule in (21)
5. Repeat steps 3 and 4 until the change in the probability is less than a chosen threshold or equal to a chosen number of interactions.

THE GMM-RL CLASSIFICATION

It now becomes clear that for a successful performance of relaxation method process, the initial label probabilities and the compatibility coefficients need to be well determined. Wrong estimates of these parameters will lead to algorithmic instabilities. In the GMM-based classification, the initial probabilities in the RL are defined as the *a posteriori* probabilities. Objects are now features vectors considered in the GMM and labels are classes of performance identification. Unlike the relaxation labeling for image recognition where the m-connected neighboring pixels may belong to different regions, in performance identification, all unknown feature vectors in the sequence $X=\{x_1, x_2,...,x_T\}$ are known to belong to a certain class of performance λ. Therefore there is no need to considerer the compatibility between an input vector and its adjacent vectors [22]. This leads to:

$$p_{t'}(\lambda_l) = p_t(\lambda_l) \qquad (22)$$

which means that compatibility between different labels is only considered for same object and therefore the updating rule in (21) should be now rewritten [22] as follows:

$$p_t^{(m+1)}(\lambda_k) = \{p_t^{(m)}(\lambda_k)[1- q_t^{(m)}(\lambda_k)]\} \;/\; \{\Sigma^{N}_{k=1}\ p_t^{(m)}(\lambda_k)[1- q_t^{(m)}(\lambda_k)]\} \qquad (23)$$

The GMM-RL algorithm for class of performance identification is stated as follows.

1. Estimate the initial probabilities for each class of performance using the a posteriori probabilities in (3):

$$p_t(\lambda_k) = p(\lambda_k|x_t)= [p(x_t\,|\lambda_k)\, p(\lambda_k)] \;/\; [\,\Sigma^{N}_{k=1}\ p(x_t\,|\lambda_k)\, p(\lambda_k)] \qquad (24)$$

where $p(\lambda_k)=1/N$ and $p(x_t\,|\lambda_k)$ is computed as in (1)

2. Compute the compatibility coefficients using (17) or (18), where $t'=t$ (no neighbors considered);
3. Calculate the updating factor defined in (19), where $t'=t$ and $d_{tt'}=1/T$ for simplicity;
4. Update the probabilities for each class of performance using the updating rule in (23);
5. Repeat steps 3 and 4 until the change in the probability is less than chosen threshold or equal to a chosen number of interactions;
6. The probability of each class of performance $p(\lambda_k)$ after RL algorithm is computed by:

$$p(\lambda_k) = \Pi^{T}_{t=1}\ p_t(\lambda_k) \qquad (25)$$

where $p_t(\lambda_k)$ is the a posteriori probability used in (10). Therefore, the decision rule for class of performance identification is as follow [22]:

Select class of performance k if*

$$k^* = \underset{1\le k\le N}{\arg\max}\ p(\lambda_k) \qquad (26)$$

THE EVALUATION TOOL

The evaluation tool proposed should supervise the user movements and others parameters associated to it. In the virtual reality simulator the trainee must extract the bone marrow. In the first movement, he must feel the skin to find the best place to insert the needle. After, he must feel the tissue layers (epidermis, dermis, subcutaneous, periosteum and compact bone) trespassed by the needle and stop at the correct position to do the bone marrow extraction. In our system the trainee movements are monitored by variables as: acceleration, applied force, spatial position, torque and angles of needle.

For the evaluation an expert executes several times the procedure for each class of performance available, for example: "well qualified", "need some training yet", "need more training", "novice", etc. So, the information of variability about these procedures is acquired using Gaussian Mixture Models and Relaxation Labeling (GMM-RL). When a trainee uses the system his performance is compared with the N classes of performances and a probability of trainee's performance for each class of performance is calculated using (24). Finally, according to (26) trainee's performance is labeling and trainee receives a report with all possible classes of performance and its respective probabilities about his performance.

CONCLUSIONS AND FUTURE WORKS

In this paper we presented a new approach to online evaluation in training simulators based on virtual reality using an elegant statistical formalism of GMM-RL. This approach provides the use of continuous variables without lost of information. So, it solves the problem of low complexity of online evaluators, without compromise performance of simulator and with good accuracy evaluation.

Systems based on_this approach can be applied in virtual reality simulators for several areas and can be used to classify the trainee into classes of learning giving him a real position about his performance, through the reports of performance of each training. In medicine, it provides an appropriate methodology for blind made procedures.

As future work, we intend to make a statistical comparison between two groups of trainees when they use or not use this system to determine differences in the increasing of learning.

AN EDUCATIONAL COMPUTER TOOL TO ANALYZE THE CORRELATOR

Luciano L. Mendes[1], Daniel Mazzer[2], Arley H. Salvador[3] and José S. G. Panaro[4]

Abstract *— Today, the knowledge about techniques of digital signals transmission is fundamental for telecommunications engineering students. As another time the COMPACT DISC substituted the vinyl, nowadays the analog transmission links are being replaced by digital ones. In digital communication systems, there are some devices that are used to optimize the signal to noise ratio in the receiver. This procedure improves the performance of the system, reducing the bit error rate. The most common technique used to receive digital signal is the correlator, which is an optimum method to detect digital signals in Additive White Gaussian Noise channels. The purpose of this paper is to show a didactical approach to analyze the correlator, using a computer program to presents each step in the detection of a digital signal.*

INTRODUCTION

In the digital communication links, the most important factor of the system is the reliability. However, there is a trade-off between reliability and transmitted power. The bit error rate (BER) [1] is the main parameter used to measure the reliability of the system. When a signal is transmitted on an Additive White Gaussian Noise (AWGN) channel, the interference of the noise in the transmitted signal depends on the signal to noise ratio (SNR). To minimize the BER, it is necessary to improve the SNR in order to reduce the effects of the noise in the received signal. The SNR can be improved by increasing the transmitted power or by reducing the effects of the noise in the receiver. The correlator is a device used in the reception of digital signals that maximizes the SNR by reducing the interference of the noise. Because of it, it is important to analyze and to study this technique. In this paper, the correlator will be simulated in a program based on block structures, named VisSim®, which facilitates the apprenticeship of this issue.

AWGN CHANNEL

The AWGN is an undesired signal that cannot be avoided [1][2]. The random nature of this signal makes necessary to analyze it based on stochastic processes, where the mean value and the variance are the main parameters to determine the behavior of the signal. The mean value represents the DC voltage of the random signal, while the variance represents the power of the AC component [1]. The standard deviation of the random signal, defined as the square root of the variance, represents the RMS voltage of the signal. Figure 1 shows a gaussian signal with zero mean and unity variance, while figure 2 shows a bipolar signal, or non-return to zero (NRZ) perturbed by an AWGN.

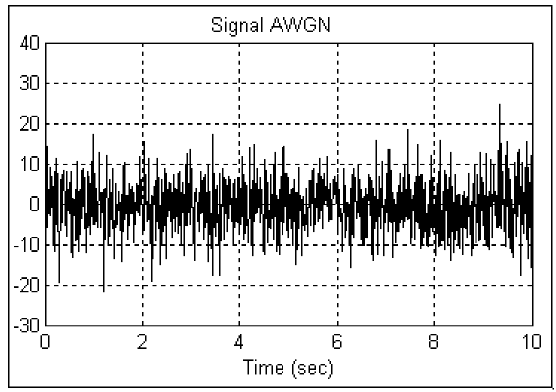

FIGURE 1
GAUSSIAN NOISE

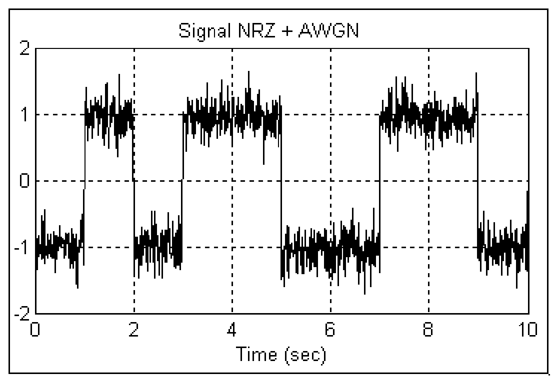

FIGURE 2
BIPOLAR SIGNAL WITH GAUSSIAN NOISE

In Figure 2, the noise may introduce errors in the transmitted data when its amplitude assumes absolute values greater than unity.

ORTHOGONALIZATION OF SIGNALS

The transmission of digital data is based on a set of waveforms of finite size. These waveforms can be represented as functions of the orthogonal bases of the set.

[1] Luciano Leonel Mendes, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, lucianol@inatel.br
[2] Daniel Mazzer, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, daniel_mazzer@inatel.br
[3] Arley Henrique Salvador, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, arley_henrique@inatel.br
[4] José Santo Guiscrafé Panaro, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, panaro@inatel.br

In this session, the Gram-Schmidt process [1][2] will be presented. This process is used to define the bases of the waveforms set.

Suppose a set of M waveforms $\{s_1(t), s_2(t), \ldots, s_M(t)\}$. Accepting the signal $s_1(t)$ as an orthogonal signal, the function of the first base $\phi_1(t)$ will be

$$s_{11} = \sqrt{E_1} \quad \Rightarrow \quad \phi_1(t) = \frac{s_1(t)}{\sqrt{E_1}} \tag{1}$$

Where E_1 is the energy of the signal $s_1(t)$.

The second orthogonal bases, $\phi_2(t)$, can be obtained using the signal $s_2(t)$ and the first orthogonal bases found by (1), $\phi_1(t)$.

$$\begin{aligned} s_{21} &= \int_0^T s_2(t)\phi_1(t)dt \\ g_2(t) &= s_2(t) - s_{21}\phi_1(t) \\ \phi_2(t) &= \frac{g_2(t)}{\sqrt{\int_0^T g_2^2(t)dt}} \end{aligned} \tag{2}$$

The procedure above must be repeated to identify the N orthogonal bases of the set, as shown in (3).

$$\begin{aligned} s_{ij} &= \int_0^T s_i(t)\phi_j(t)dt, \quad g_i(t) = s_i(t) - \sum_{j=1}^{i-1} s_{ij}\phi_j(t) \\ \phi_i(t) &= \frac{g_i(t)}{\sqrt{\int_0^T g_i^2(t)dt}} \end{aligned} \tag{3}$$

Where $i = 1,2,3,\ldots,N$ e $j = 1,2,3,\ldots,i-1$.

The number of orthogonal bases (N) can be equal or less than the number of waveforms of the set (M). If the signals $\{s_1(t), s_2(t),\ldots, s_M(t)\}$ are linearly independent (orthogonal), then $N = M$. If the signals $s_1(t), s_2(t),\ldots, s_M(t)$ are not linearly independent, then $N < M$.

Any waveform from the set can be represented as a linear combination of the N orthogonal bases, thus the transmitter and the receiver do not have to handle with M waveforms, but only with N waveforms.

The waveforms can be geometrically represented in a vector diagram, where the axes are the orthogonal bases found in the Gram-Schmidt process. For the geometric representation of the signals, each orthogonal base must be normalized to unitary energy. Finally, any signal, $s_i(t)$, can be expressed as shown in (4).

$$s_i(t) = \sum_{j=1}^{N} s_{ij}\,\phi_j(t), \qquad \begin{cases} 0 \le t \le T \\ i = 1,2,\ldots,M \\ j = 1,2,\ldots,N \end{cases} \tag{4}$$

Where the coefficients s_{ij} represent the projection of the signal $s_i(t)$ over the base $\phi_j(t)$ and can be obtained by (5).

$$s_{ij} = \int_0^T s_i(t)\,\phi_j(t)\,dt, \qquad \begin{cases} i = 1,2,\ldots,M \\ j = 1,2,\ldots,N \end{cases} \tag{5}$$

Thus, it is possible to represent any signal from the set as a linear combination of the orthonormal bases, as shown in Figure 3.

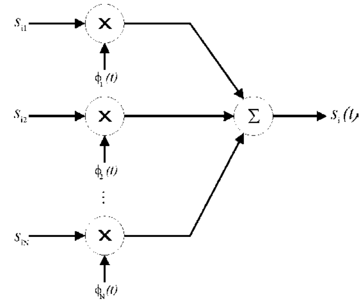

FIGURE 3.
LINEAR COMBINATION OF THE ORTHONORMAL BASES.

It is also possible to geometrically represent the signals from a set, where the number of orthogonal bases is three or less. Figure 4 shows a example of a set with three signals and two orthonormal bases (N=2 and M=3).

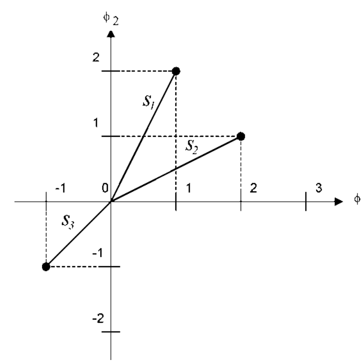

FIGURE. 4
GEOMETRIC REPRESENTATION OF SIGNALS

CONSTELLATIONS OF DIGITAL MODULATIONS

In digital communications, the symbols are represented as waveforms and are transmitted as functions of the orthogonal bases. In phase and/or amplitude modulations, the orthogonal bases usually are the sine and cosine with the same frequency. For example, the QPSK (Quadrature Phase Shift Keying) modulation [1][2] has four possible symbols that can be defined by the combination of two bits. Figure 6 shows the constellation of this modulation technique, where M=4 and N=2. The orthogonal bases are defined by (6).

$$\phi_1(t) = \cos(\omega \cdot t)$$
$$\phi_2(t) = \text{sen}(\omega \cdot t) \quad (6)$$

Where ω is the angular frequency of the carrier.

Any symbol $s_i(t)$ can be defined as a linear combination of these two bases, as shown by (7).

$$\begin{aligned} s_1(t) &= +\cos(\omega \cdot t) + \text{sen}(\omega \cdot t) \\ s_2(t) &= -\cos(\omega \cdot t) + \text{sen}(\omega \cdot t) \\ s_3(t) &= -\cos(\omega \cdot t) - \text{sen}(\omega \cdot t) \\ s_4(t) &= +\cos(\omega \cdot t) - \text{sen}(\omega \cdot t) \end{aligned} \quad (7)$$

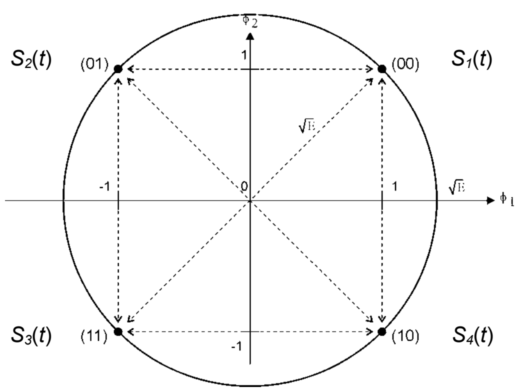

FIGURE. 6
QPSK CONSTELLATION.

CORRELATOR

In a digital communication link, the received link is corrupted by the AWGN. To minimize the number of errors introduced by the channel, it is necessary to maximize the signal to noise ratio. The correlator represents one technique that realizes this operation. Figure 7 shows the block diagram of the transmission and reception of signal from a set of *M* waveforms and 2 orthogonal bases.

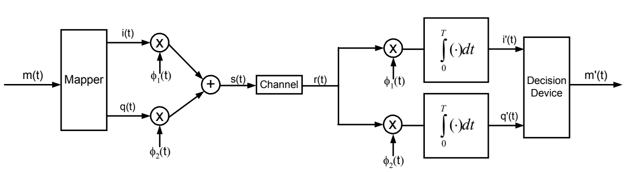

FIGURE 7.
BLOCK DIAGRAM OF A DIGITAL COMMUNICATION LINK.

The transmitted bits are mapped in two orthogonal signals ($i(t)$ and $q(t)$) that have $\sqrt{M}$ possible levels. These two signals are multiplied by the orthogonal bases of the set and then applied in the communication channel. The received signal, r(t), is multiplied by the bases and integrated at each symbol time (T), generating the estimated signals $i'(t)$ and $q'(t)$. These signals are applied to a decision device that estimates the transmitted data sequence $m'(t)$. It is desirable to have a received data sequence equal to the transmitted data sequence.

SIMULATION

In this session, a simulation based on the block diagram of figure 7 will be presented. Figure 8 shows the transmission simulator, while figure 9 shows the receiver simulator.

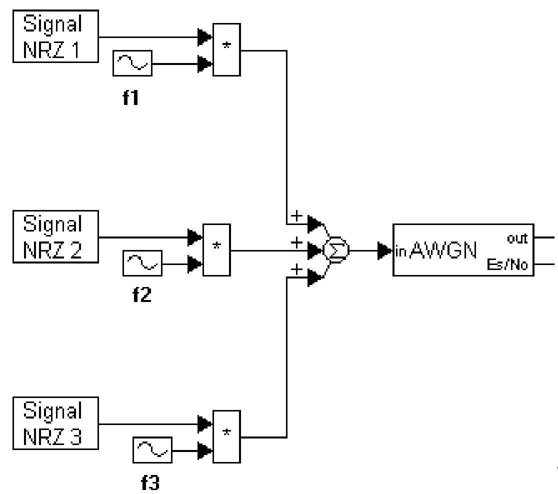

FIGURE 8
TRANSMITTER SIMULATOR

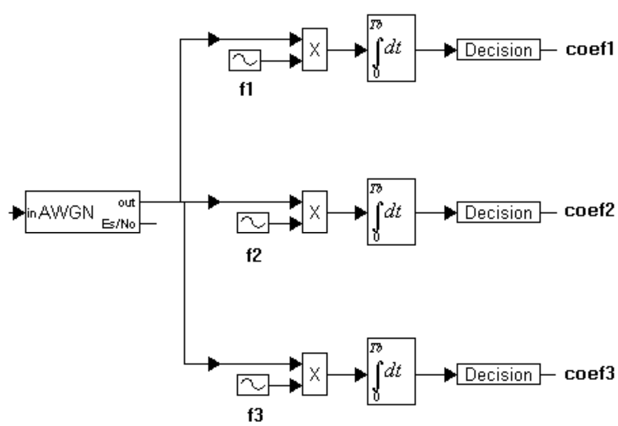

FIGURE 9
RECEIVER SIMULATOR

In this simulation, three bipolar signals are transmitted using three orthogonal bases that are sine functions with frequencies *f1*=1Hz*, f2*=2Hz and *f3*=3Hz. Figure 10 shows the added signals at the output of the AWGN channel.

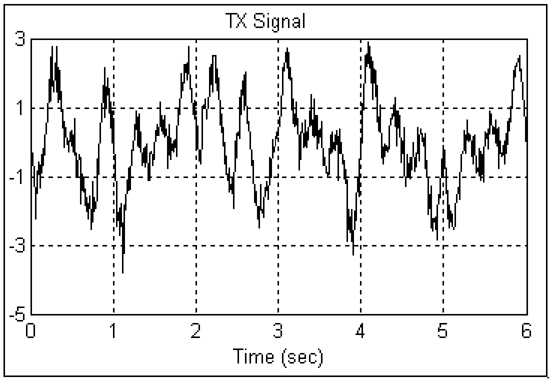

FIGURE. 10
RECEIVED SIGNAL

The received signal is applied to three correlators, one for each transmitted signal. First, the received signal is multiplied by the orthogonal bases. Figure 11 shows the received signal multiplied by the first orthogonal base.

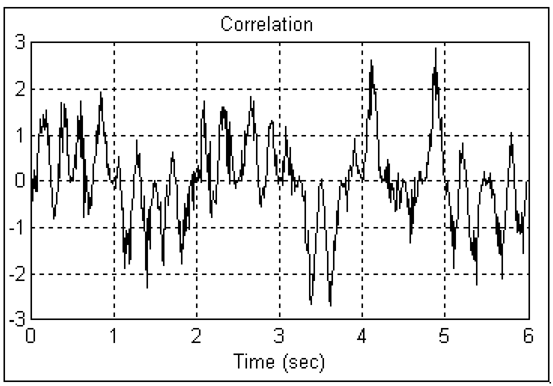

FIGURE 11
DETECTION OF THE RECEIVED SIGNAL

The second step of the receiving process is to integrate the signal during the symbol duration, *T*. In this simulation, the symbol rate is one symbol per second. Thus, the symbol time is one second. Figure 12 shows the output of the first integrator.

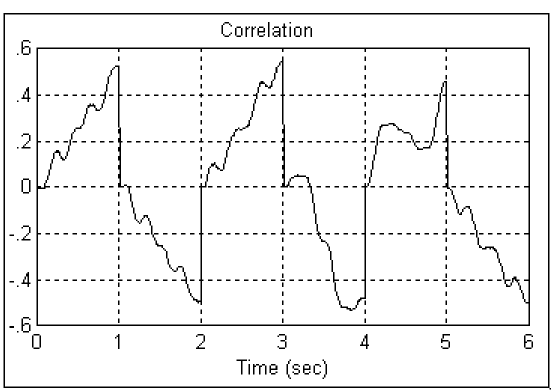

FIGURE 12
INTEGRATOR OUTPUT.

The decision device samples the integrated signal at each *T* seconds and, for each received signal, decides for bit 1 if the sample is positive, and for bit 0 if the sample is negative. Figure 13 shows the output of the sampler while figure 14 shows the output of the decision device.

OUTPUT OF THE DECISION DEVICE

CONCLUSION

The optimum receiving process is a very important issue in digital communications studies and must be clearly presented to Telecommunication Engineering students. This paper presented an educational approach to analyze the correlator, using a computer tool to show each step of the transmission and receiving processes. Thus, the students are able to verify how a transmitted data signal behaves in the communication block diagram.

Resumo — O objetivo deste artigo é apresentar um conjunto de ferramentas computacionais para análise do sistema de Multiplexação por Divisão de Freqüências Ortogonais. Apresenta-se simulações realizadas em três plataformas distintas, sendo elas, MatLab®, Mathcad® e VisSim®. Com esses programas é possível analisar e comparar o comportamento dos sinais em cada etapa do processo de transmissão e recepção, tanto na técnica com múltiplas portadoras quanto na técnica de portadora única.

Palavras-chaves — OFDM, Força Bruta, FFT, IFFT.

INTRODUÇÃO

O crescimento dos serviços digitais (Internet, vídeo sob demanda, etc.) requer um aumento na taxa de dados. Porém, com transmissão em banda larga, o sinal passa a ser susceptível ao desvanecimento seletivo causado pela propagação em canais com múltiplos percursos. Uma solução encontrada para este problema foi dividir o feixe de dados serial em vários feixes paralelos e transmiti-los em várias portadoras ortogonais, que é o princípio da técnica de transmissão digital OFDM (*Orthogonal Frequency Division Multiplexing*).

O OFDM é utilizado em padrões de transmissão comercial de áudio e vídeo, como por exemplo DAB (*Digital Audio Broadcasting*) e DVB-T (*Digital Video Broadcasting – Terrestrial*) que é o padrão usado na transmissão de HDTV (*High Definition Television*) na Europa [1]. Esta técnica apresenta eficiência em largura de faixa, alta robustez aos problemas de interferência entre símbolos, desvanecimento seletivo em freqüência e ruído impulsivo. Sua desvantagem é a maior complexidade de implementação em relação ao sistema de portadora única.

Neste artigo, foram utilizados os programas: VisSim®, Mathcad® e MatLab®. O VisSim® é um simulador de comunicações digitais que facilita a implementação do sistema, devido a sua estrutura em blocos. O Mathcad® e o MatLab® são softwares matemáticos que permitem realizar simulações através das equações que definem o comportamento do sistema.

Existem duas maneiras de se implementar um sistema OFDM: o método da força bruta ou o método que usa transformada rápida de Fourier (FFT) [2].

O objetivo deste artigo é propor uma abordagem que ajude na compreensão do OFDM apresentando simulações de ambos os métodos de implementação.

MÉTODO DA FORÇA BRUTA

O princípio de geração de um sinal OFDM pelo método da Força Bruta pode ser divido em três fases, conforme apresentado na Figura 1:

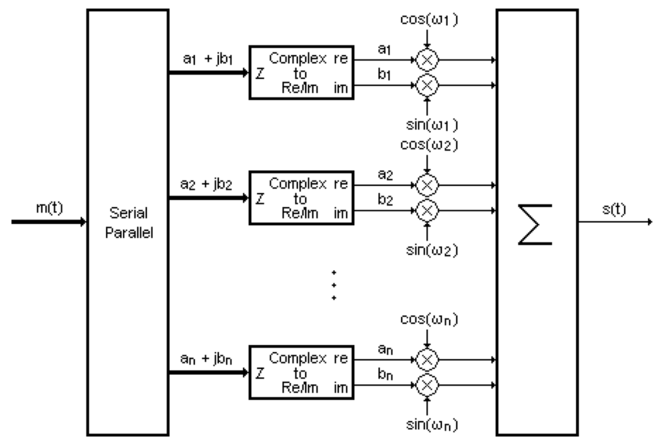

FIGURA 1
DIAGRAMA EM BLOCOS DE UM TRANSMISSOR OFDM USANDO O MÉTODO DA FORÇA BRUTA

Na primeira fase, o feixe de dados original é dividido em N feixes paralelos através de um conversor serial paralelo. Tanto o sinal de entrada quanto os sinais de saída deste conversor podem ser sinais complexos, dependendo do tipo de modulação digital utilizada [3]. A modulação BPSK (*Binary Phase Shift Keying*) utiliza apenas o eixo real para representar os símbolos da constelação, ao passo que as modulações M-PSK (*Phase Shift Keying*) e M-QAM (Q*uadrature Amplitude Modulation*) utilizam tanto o eixo real quanto o eixo imaginário.

Na segunda fase, os N feixes paralelos (N_1, N_2, ... , N_P) são modulados em N portadoras complexas e ortogonais (ω_1, ω_2, ... , ω_P) igualmente espaçadas. A parte real do sinal N_n será modulada por cos(ω_n) e a parte imaginária do sinal N_n será modulada por sen(ω_n), onde n pode assumir valores entre 1 e p. Finalmente, na terceira fase, os N sinais modulados são somados gerando um sinal OFDM.

[2] Henrique T. Kuehne, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, htkuehne@inatel.br
[3] Luciano Leonel Mendes, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, lucianol@inatel.br
[4] José Santo G. Panaro, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, panaro@inatel.br

O sinal OFDM é detectado utilizando a propriedade de ortogonalidade das portadoras, ou seja, utiliza-se filtros casados ou correlatores para receber os sinais N_n, que são aplicados em um conversor paralelo serial e finalmente demodulados em uma seqüência de bits. A Figura 2 mostra o diagrama em blocos de um receptor OFDM genérico.

A implementação deste método pode-se tornar inviável caso o número de portadoras (*N*) seja elevado, pois nesta abordagem, são necessários *N* osciladores para fornecer as portadoras ortogonais necessárias para a geração do sinal OFDM.

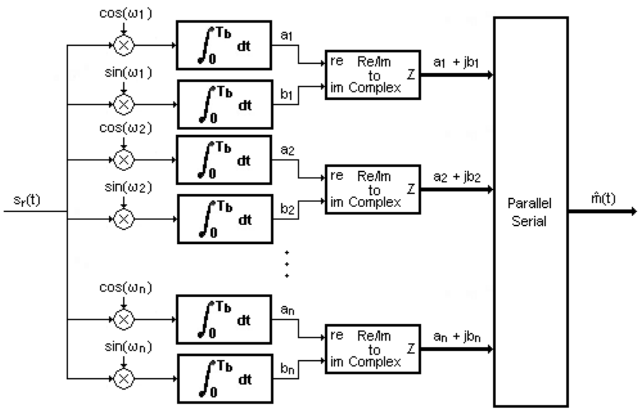

FIGURA 2
DIAGRAMA EM BLOCOS DE UM RECEPTOR OFDM USANDO O MÉTODO DA FORÇA BRUTA

A seguir são apresentados alguns resultados e comentários obtidos a partir de simulações utilizando a abordagem apresentada. Nesta simulação, um sinal OFDM de 4 portadoras é gerado pelo método da Força Bruta. Cada portadora é modulada por um sistema PAM(*Pulse Amplitude Modulation*) de 16 níveis, com taxa de 32 símbolos por segundo. A figura 3 mostra o espectro do sinal OFDM, bem como o espectro de cada subportadora, onde é possível observar a ortogonalidade entre os sinais.

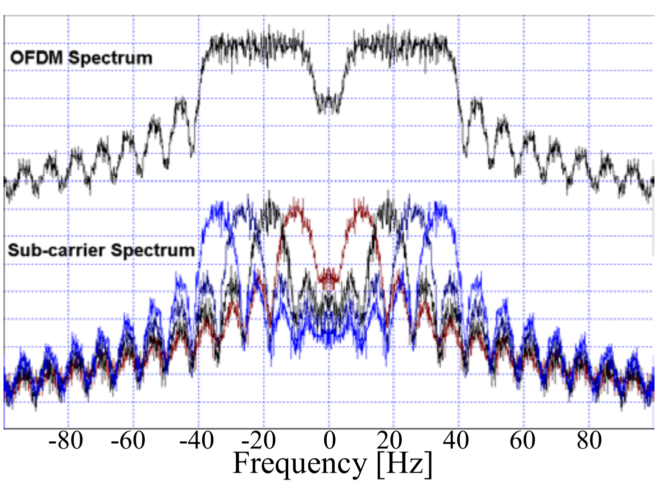

FIGURA 3
ESPECTRO DO SINAL OFDM E DAS SUBPORTADORAS .

A soma das subportadoras resulta no espectro do sinal OFDM apresentado. O sinal OFDM no domínio do tempo, possuí distribuição gaussiana, aproximando-se do ruído AWGN a medida em que o número de subportadoras aumenta.

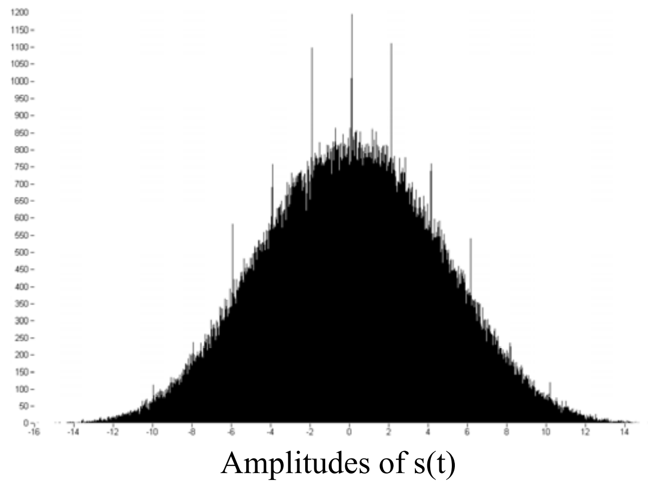

FIGURA 4
HISTOGRAMA DAS AMPLITUDES DO SINAL OFDM.

A figura 4 mostra o histograma das amplitudes do sinal OFDM, enquanto que a figura 5 mostra o sinal OFDM no domínio do tempo.

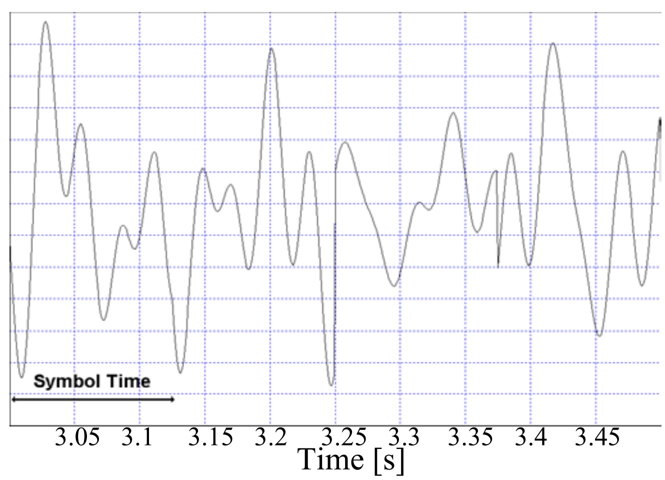

FIGURA 5
SINAL OFDM NO DOMÍNIO DO TEMPO.

GERAÇÃO E RECEPÇÃO DE SINAIS OFDM ATRAVÉS DA FFT.

No método apresentado a seguir, utiliza-se a Transformada Rápida de Fourier para gerar o sinal OFDM. Desta forma não é mais necessário gerar as N portadoras individualmente, conforme apresentado na sessão anterior. Isto permite o uso de um número maior de portadoras sem um aumento significativo da complexidade do sistema, mas com aumento da carga computacional. Neste caso, o princípio de geração do sinal OFDM pelo método da FFT pode ser separado em duas partes. A primeira parte deste método é idêntica à primeira fase do método da Força Bruta, gerando os sinais paralelos que representam as amplitudes das portadoras complexas no domínio da freqüência. Na segunda parte do processo, realiza-se a transformada rápida de Fourier inversa (IFFT) para obter o sinal OFDM no domínio do tempo, conforme apresentado na Figura 6. O sinal resultante é o sinal OFDM em banda básica. Para obter um sinal em banda passante basta transladar o sinal obtido para a freqüência do canal desejado.

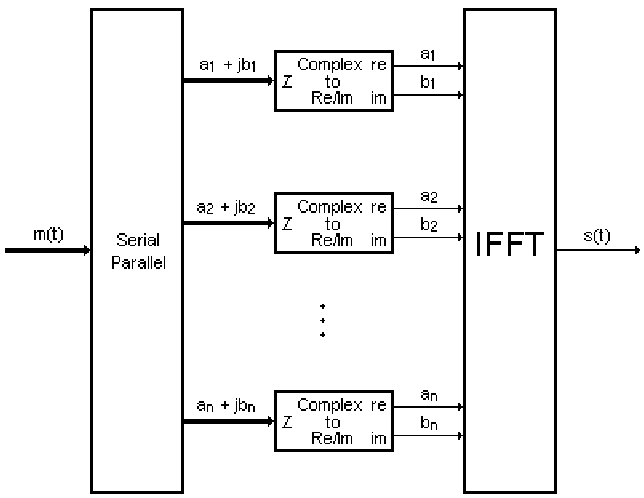

FIGURA 6
DIAGRAMA EM BLOCOS DE UM TRANSMISSOR OFDM USANDO O MÉTODO DA FFT

A recepção deste sinal por este método acontece de maneira análoga porém invertida ao processo de geração. Primeiro realiza-se a transformada rápida de Fourier (FFT) de ordem *N* do sinal OFDM em banda básica, gerando *N* sinais. Depois, estes *N* sinais são aplicados em um conversor paralelo serial e finalmente entregues ao demodulador digital para que os bits transmitidos sejam recuperados. A figura 7 mostra o diagrama em blocos de um receptor OFDM.

A seguir são apresentado os resultados obtidos em simulação de um transmissor OFDM_ utilizando o método da FFT. Os dados originais são mapeados em 16 símbolos, transmitidos a uma taxa de 32 símbolos por segundo. A figura 8 mostra o espectro do sinal OFDM em banda básica, gerado através do diagrama apresentado na figura 6.

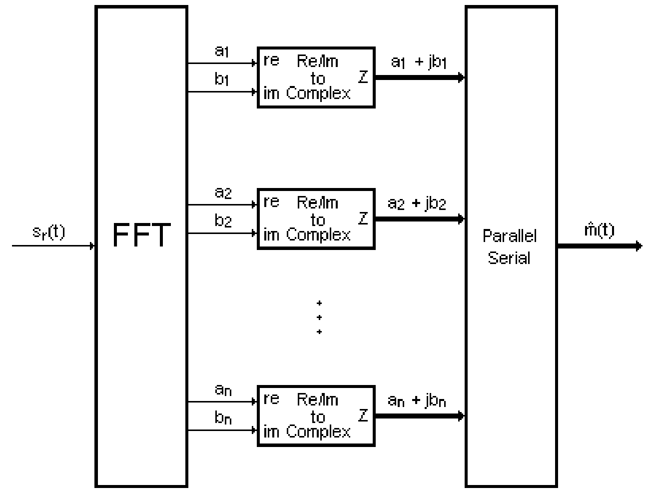

FIGURA 7
DIAGRAMA EM BLOCOS DE UM RECEPTOR OFDM USANDO O MÉTODO DA FFT

Como pode ser visto, o sinal OFDM gerado pelo método da FFT está em banda básica e necessita ser transladado para a freqüência do canal. Como o processo de translação na freqüência é um processo linear, pode-se realizar a análise em banda básica, sem perda de generalidade.

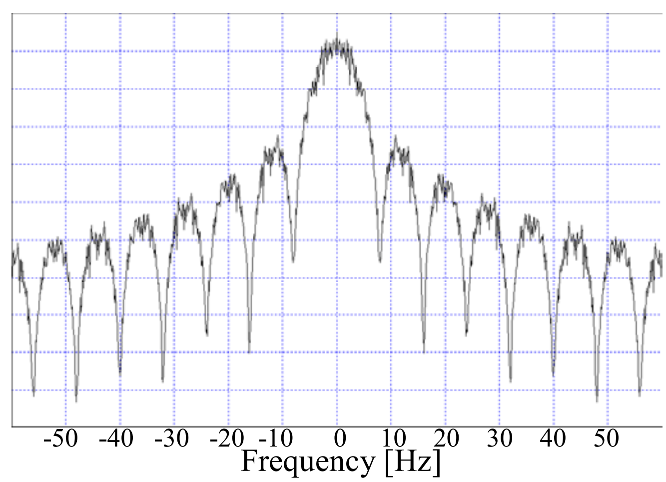

FIGURA 8
ESPECTRO DO SINAL OFDM GERADO ATRAVÉS DO MÉTODO DA FFT.

A figura 9 mostra o espectro o histograma das amplitude do sinal OFDM gerado pelo método da FFT enquanto que a figura 10 mostra o sinal OFDM no domínio do tempo.

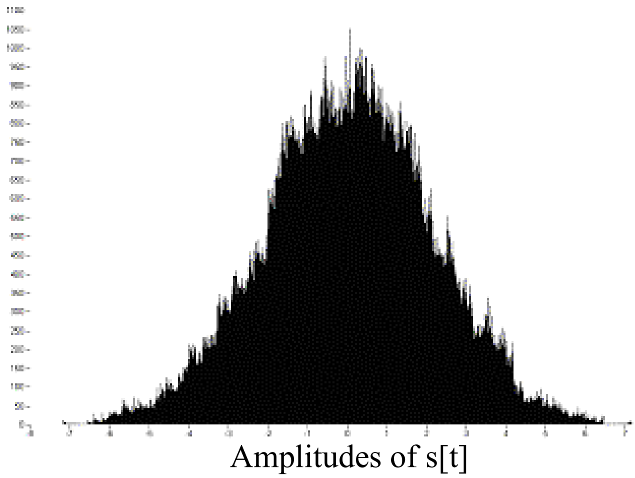

FIGURA 9
HISTOGRAMA DE AMPLITUDES DO SINAL OFDM.

Através da figura 9, é possível observar que a distribuição das amplitude do sinal OFDM gerado pelo método apresentado nesta sessão, também possui uma distribuição gaussiana.

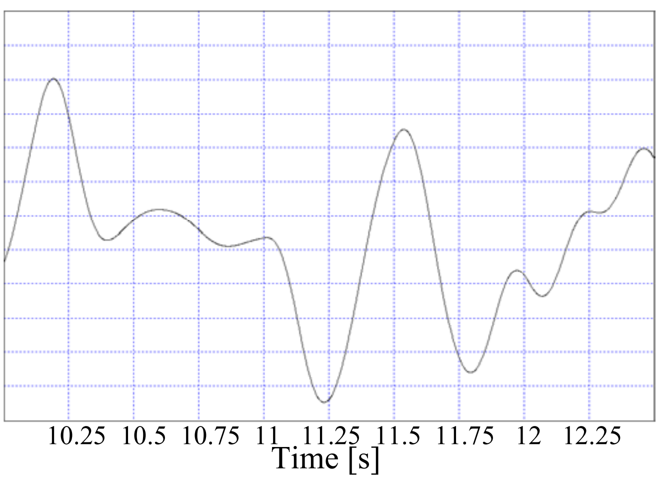

FIGURA 10
ANÁLISE DO SINAL OFDM NO DOMÍNIO DO TEMPO.

O problema inerente a sinais com distribuição gaussiana é a amplificação [4]. Os amplificadores utilizados em transmissão de sinais de RF(*Radio frequency*) possuem alto rendimento, ou seja, trabalham próximos do ponto de saturação da curva de carga. Assim, os picos de amplitude do sinal OFDM levam o amplificador a condição de corte, o que introduz um ceifamento no sinal amplificado. Esse ceifamento causa uma diminuição no desempenho do sistema OFDM, ou seja, há um aumento na taxa de erro de bit no sinal recebido.

CONCLUSÃO

Os princípios utilizados para a geração de sinais OFDM permitem que os moduladores e demoduladores sejam gerados utilizando duas técnicas distintas. A primeira técnica, chamada de Método da Força Bruta, gera o sinal OFDM através da soma de N portadoras complexas ortogonais. Neste método, cada portadora é gerada por um oscilador local, o que torna inviável sua implementação para valores elevados de N.

A método para a geração de sinais OFDM utiliza a propriedade da Transformada Rápida de Fourier para a geração das portadoras ortogonais. Neste método, os dados a serem transmitidos são tomados como amplitudes de N tons senoidais. Portanto, a Transformada Rápida de Fourier Inversa destes dados gera, no domínio do tempo, um símbolo OFDM composto pela soma de N portadoras ponderadas pelo sinal de entrada. Neste caso, não é necessário construir N osciladores complexos, o que permite a implementação de sistemas OFDM com até milhares de portadoras.

A abordagem de ambos os métodos pode apresentar resultados didáticos interessantes, uma vez que o aluno pode verificar e comparar o funcionamento do sistema OFDM de maneiras distintas, o que pode facilitar a compreensão dos assuntos abordado. O uso de ferramentas computacionais para apresentar os resultados obtidos em cada etapa do processo de modulação e demodulação do sinal OFDM também é fundamental para que a abordagem do assunto se torne clara e didática.

Analysis of Clipping in OFDM Symbols

Luciano L. Mendes[1], Sandro A. Fasolo[2] and Geraldo G. R. Gomes[3]

Abstract *— The purpose of this paper is to present the problems introduced in a Multicarrier Modulation (MCM) symbols by a nonlinear channel. The signal at the output of a multicarrier modulator has a very high peak to average power ratio and the amplifier can clip its peak values. In this paper, a simulation showing the interference of the clipping process in the performance of a multicarrier communication system will be presented with some commented results. The program used to simulate MCM systems has been developed using Matlab® platform and has the didactical objective of showing the principles involved on this issue.*

Index Terms — Clip, Multicarrier Modulation, OFDM.

INTRODUCTION

The advent of digital television and wireless local area network (WLAN) brought the necessity of transmission of digital data at high rates [1]. One technique that has being used to archive the required data rate is the Orthogonal Frequency Division Multiplexing (OFDM). The OFDM system is a multicarrier modulation where the frequencies of the sub-carriers are orthogonal. This technique is being widely used to transmit data at high rates because of its robustness to the multipath channel [1][2].

The OFDM signal is obtained by adding N orthogonal sub-carriers, each one modulated by a sequence of data. Thus, by the Central Limit Theorem [3], the OFDM symbol can be modeled as a Gaussian Process [4], where the amplitude of the signal has normal distribution. Because of it, the OFDM signal may have high peaks, which leads to a very high Peak to Average Power Ratio (PAPR). To transmit this signal, the power amplifier must have a wide linear operation region, which is difficult to archive. It means that the power amplifier may clip the high peaks of the OFDM signal, introducing a nonlinear interference in the transmitted signal. This paper will present a computer tool developed to analyze this nonlinear interference in the OFDM system, with some commented results.

CLIPPING OF AN OFDM SIGNAL

The OFDM system is based on parallel communication, where the data sequence is convert to N parallel sequences, which modulates N orthogonal sub-carriers. Figure 1 shows the block diagram of an OFDM modulator.

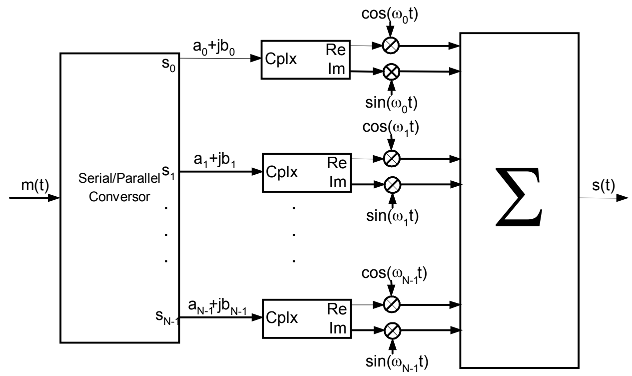

FIGURE 1
OFDM MODULATOR.

The data signal, $m(t)$, is the base band signal provided by any digital modulator, such as BPSK (Binary Phase Shift Keying), QPSK (Quadrature Phase Shift Keying) or QAM (Quadrature Amplitude Modulation), and it can be a complex signal. The data signal is converted to N parallel symbols, ($s_0, s_1, s_2, ..., s_{N-1}$), and the real component of each signal is modulated by a cosine function, while the imaginary component is modulated by a sine function. The angular frequencies of each sub-carrier are chosen to be orthogonal in order to satisfy (1).

$$\int_0^{Ts} \cos(\omega_i t)\cdot\cos(\omega_j t)dt = 0 \quad ; i \neq j \tag{1}$$

Where T is the OFDM symbol time.

If the signal $m(t)$ is a random sequence, the resulting OFDM signal, $s(t)$, can be modeled as a sum of N random variables, as shown by (2).

$$s(t) = \mathrm{Re}\left\{\sum_{i=0}^{N-1} s_i(t)e^{-j\omega_i t}\right\} \tag{2}$$

The Central Limit Theorem states that the sum of independent identical distributed (iid) random variables can be modeled as a gaussian variable with the variance (σ_s^2) and mean value (μ_s) given by (3).

$$\begin{aligned}\sigma_s^{\ 2} &= N\cdot\sigma^2 \\ \mu_s &= N\cdot\mu\end{aligned} \tag{3}$$

Where σ and μ are, respectively, the standard deviation and mean value of the iid random variables. Figure 2 shows the probability density function (PDF) of an OFDM signal, with 64 carriers, modulated using QPSK.

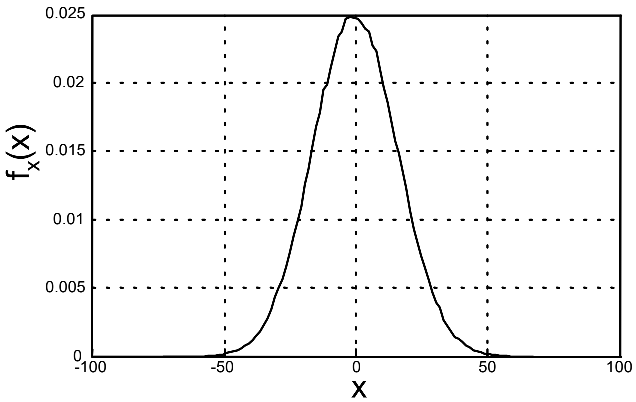

FIGURE 2
PDF OF AN OFDM SIGNAL.

It is possible to verify that the amplitude of an OFDM signal may present high values. To transmit this signal, it is necessary to apply it in an amplifier, with a very large linear operational region, but the amplifiers with this characteristic are expensive and inefficient [5]. Thus, the amplifiers usually are set for best performance and, because of it, its linear operation region is not as large as necessary to linearly amplify the OFDM signal. The high peaks of the OFDM signal may saturate the amplifier and this distortion can be modeled as a clipping effect. Figure 3 shows an OFDM signal clipped by a nonlinear power amplifier.

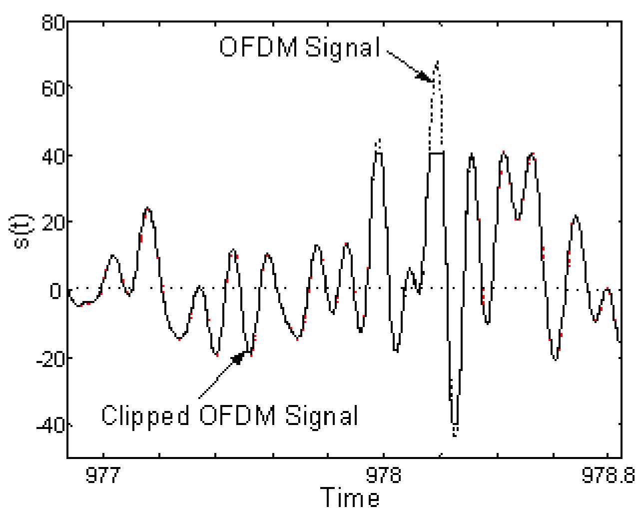

FIGURE 3
OFDM SIGNAL CLIPPED BY A NONLINEAR AMPLIFIER.

Once know why the clipping process occurs, it is important to define the influence of this interference in the system performance. In the OFDM system, the data symbols define the amplitude of each complex sub-carrier, as shown in (2). Because of this, the reception of the information is realized by detecting the amplitude of the sub-carriers in the frequency domain. Thus, the analysis of the clipping interference in the reception process should be done in the frequency domain instead of the time domain. If the number of sub-carrier (N) increases, the OFDM symbol time (T_s) also increases, as can be seen in (4).

$$T_s = N \cdot T \tag{4}$$

Where T is the symbol time of the incoming data signal, $m(t)$.

For large values of T_s, the clipped part of the OFDM signal can be approximated to an impulse, thus the clipping distortion can be modeled as an impulsive noise added to the transmitted signal, as shown in Figure 4.

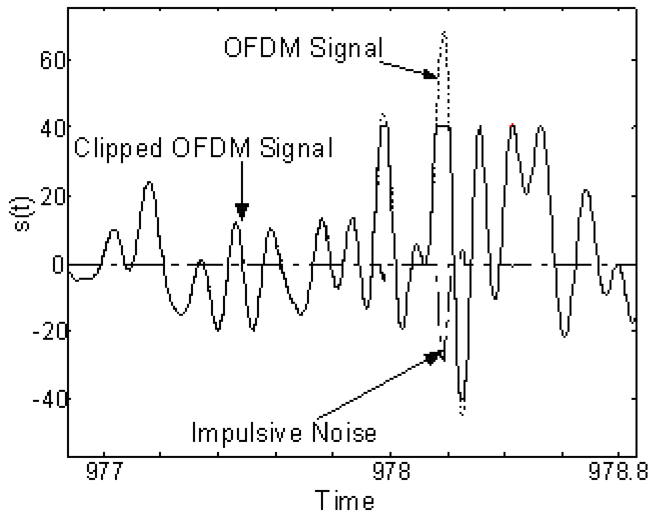

FIGURE 4
IMPULSIVE NOISE MODEL

It is known that the Fourier Transform of an impulse of amplitude α is defined by (5).

$$\mathscr{F}\{\alpha \cdot \delta(t)\} = \alpha \tag{5}$$

Equation (5) shows that the impulsive noise, in the frequency domain, represents a constant value which interferes in every sub-carrier. Thus, the impulsive noise does not destroy the information transmitted by a specific sub-carrier, but it introduces a distortion in every transmitted sub-carrier.

INFLUENCE OF THE CLIPPING DISTORTION

The reception of an OFDM signal can be implemented by a bank of correlators [6], as shown in Figure 5. The received signal, $s'(t)$, is multiplied by the N complexes sub-carriers and integrated in a OFDM symbol time. The estimated received symbols, ($s'_0, s'_1, s'_2, ..., s'_{N-1}$), are converted from parallel to serial format, generating the estimated data signal, $m'(t)$.

To analyze the effect of the clipping process, an OFDM system with 128 sub-carriers modulated with a QPSK scheme has been simulated. Figure 6 shows the transmitted data sequence, $m(t)$.

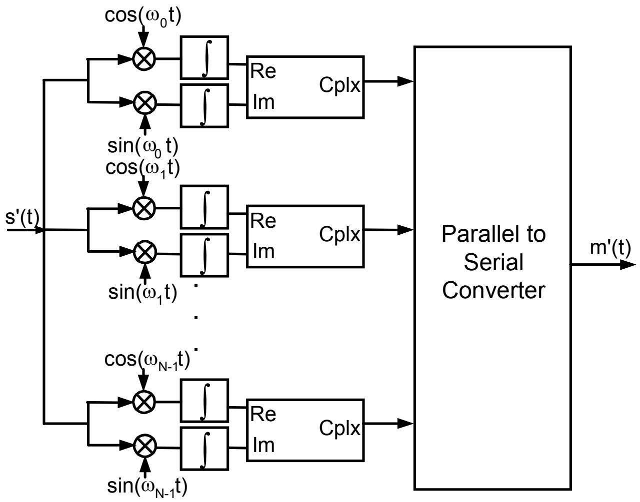

FIGURE 5
OFDM RECEIVER

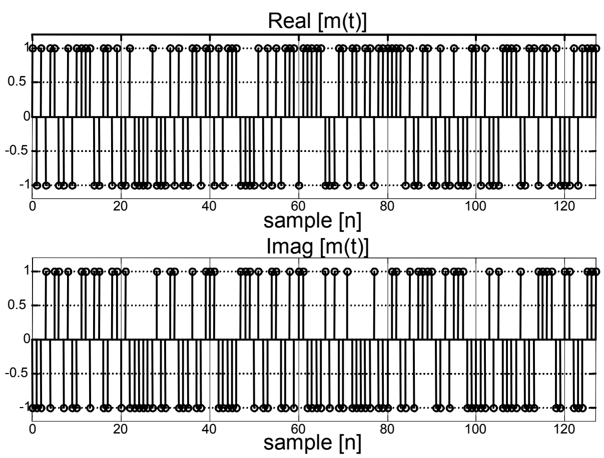

FIGURE 6
TRANSMITTED DATA SEQUENCE

The data sequence, presented in Figure 6, is applied to the OFDM modulator, generating the transmitted signal, $s(t)$, presented by Figure 7.

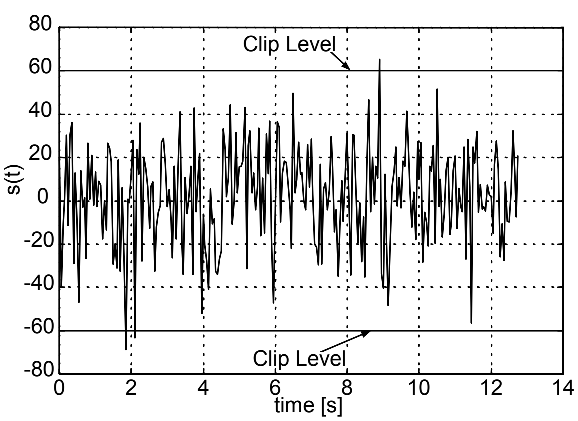

FIGURE 7
OFDM SIGNAL.

In this simulation, the clip level has been set to 60, which means that only the peaks above 60 and bellow –60 have been clipped. It is possible to observe that the introduced clipping distortion is not very high, in this case. Figure 8 shows the received data sequence, $m'(t)$.

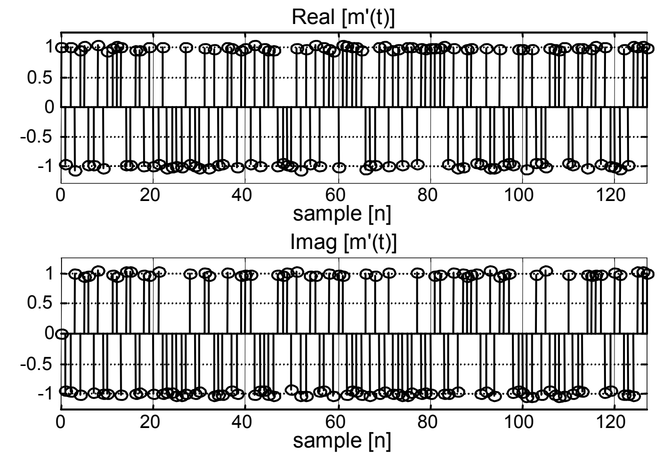

FIGURE 8
RECEIVED DATA SEQUENCE.

The clipping distortion introduces a variation in all transmitted symbols, decreasing the performance of the OFDM system.

In this simulation, the clipping occurred only in a few instants of time, because the clip level was set to a high value. In the next simulation, the clip level has been set to 30, which will introduce more clipping events to the transmitted signal, as can be seen in Figure 9.

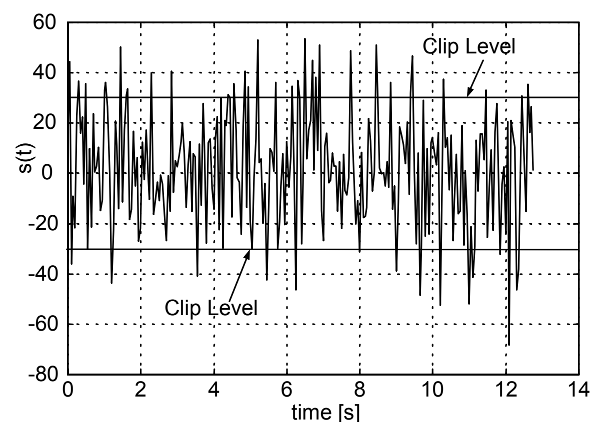

FIGURE 9
OFDM SIGNAL.

The distortion introduced by the clipping process in this simulation will perturb the transmitted data signal, reducing even more the performance of the system in a channel perturbed by AWGN (Additive White Gaussian Noise).

Figure 10 shows the received data sequence, perturbed by the clipping presented by Figure 9.

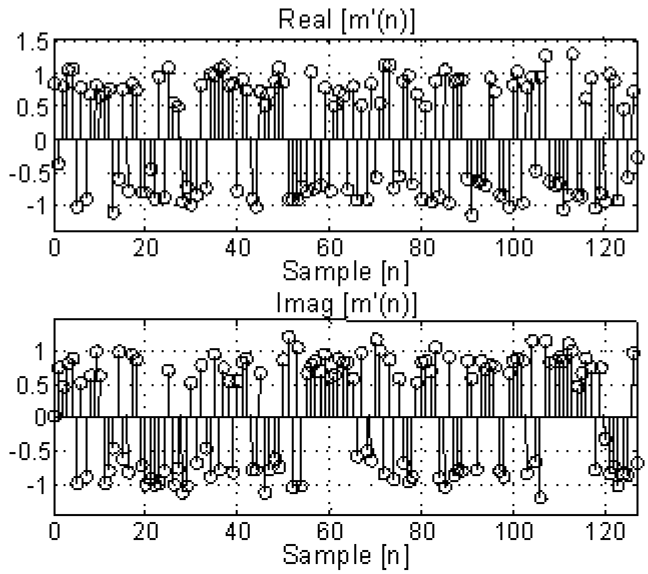

FIGURE 10
RECEIVED DATA SIGNAL.

As a quantitative parameter, the standard deviation can be used as a reference value for the clip level. In the first simulation, the clip level to the standard deviation rate was 2.66 (the standard deviation of the OFDM signal is 22.58). In the second simulation, the clip level to the standard deviation rate was 1.33. Thus, based on the simulations presented here, it is possible to observe that for ratio less than two, the interference of the clipping can be significant.

It is important to note that the clipping distortion does not introduce bit error, because the decision device can exactly approximate the received signal, $m'(t)$, to the transmitted signal, $m(t)$. However, the analysis realized in this paper, does not consider the AWGN of the channel. Thus, the clipping distortion will reduce the robustness of the system by increase the bit error rate (BER). The problems caused by the clipping can be minimized by applying a channel code for error control or by increasing the linear operation region of the power amplifier.

CONCLUSIONS

The OFDM signals can be modeled as a Gaussian Process and, thus, it may present very high amplitude values. The power amplifier used to transmit this signal usually presents a short linear region of operation due the power efficiency. Thus, the high peaks of the OFDM signal are clipped because the high values of this signal saturate the power amplifier. This distortion can be modeled as an impulsive noise that is added to the transmitted signal, and it interferes in every sub-carrier. The results presented in this paper, shows that the degradation in the system performance may be significant if the clip level is less than two times the standard deviation of the OFDM signal. It means that if the clip level is less than two times the standard deviation, the performance of the OFDM system in an AWGN channel can decrease significantly.

An Educational Approach for the Study of Wave Propagation

Luciano L. Mendes[1] and Geraldo G. R. Gomes[2]

Abstract — *The main purpose of this paper is to present an computer tool developed to simulate a point to point digital radio link. This program allows the user to explore and study the phenomena involved in the wave propagation, as example, the Fresnell's ellipsoid and the free space attenuation. The attenuation caused by obstacles is also simulated which allows the user to realize a complete analysis about the propagation of an electromagnetic wave.*

Index Terms — *Wave propagation, simulation, Fresnell's ellipsoid.*

INTRODUCTION

Today, the digital radio links are widely used in many applications. The microwave links used to transmit telephony voice are the most common application [1]. Internet wireless access is also another important application that is growing fast. Usually, the capacity of a digital radio link varies between 64Kbps (one-voice channel) and 155Mbps (one STM-1 data stream).

The microwave digital radio links, which works with in a line of sight, has two main causes that reduce the performance of the system. The first one is the non-selective fading, which reduce the SNR (signal to noise ratio). The second one is the multipath, where a delayed version of a signal interferes in the received signal. This interference is called ISI (Intersymbol Interference) [2] [3]. The ISI provokes "notches" in the desired bandwidth, which characterizes a selective fading. Figure 1 shows the spectrum of a signal in a flat channel (non-selective), while Figure 2 shows the spectrum of a signal in a selective channel.

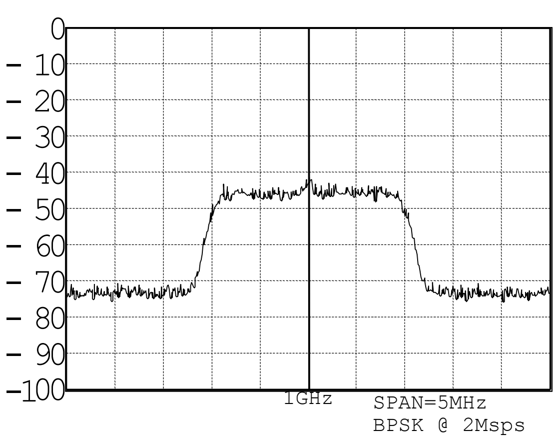

FIGURE 1
SPECTRUM OF A BPSK SIGNAL IN A FLAT CHANNEL

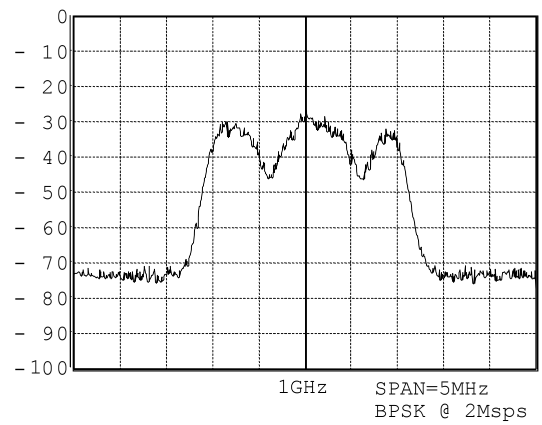

FIGURE 2
SPECTRUM OF A BPSK SIGNAL IN A SELECTIVE CHANNEL.

The weather conditions and the geometry of the links are some parameters that allow one to determine the phenomena in a link. In this paper, a computer tool to analyze microwave links is presented. This tool allows the user to verify how the parameters that define the system and the atmosphere affect the link. All results are presented in a window developed using a Graphic User Interface (GUI) over Matlab® platform [4] to provide a didactical interaction with the user.

TROPOSPHERE PROPAGATION IN LINE OF SIGHT

The trajectory described by an electromagnetic wave between the transmitter and the receiver depends, basically, on the density of the propagation medium. In the vacuum density, the electromagnetic wave propagates in a straight line, but it does not happen in the troposphere density, because it depends on the temperature, pressure and humidity. If the propagation medium does not have a uniform density, the trajectory of the electromagnetic wave is not a straight line because of the refraction phenomenon [1]. The refraction coefficient, or refraction index, n, is the ratio between the propagation speed of an electromagnetic wave in the vacuum, c_o, by the speed in the vacuum, c, as shown by (1).

$$n = \frac{c_o}{c} \tag{1}$$

[1] Luciano Leonel Mendes, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, lucianol@inatel.br
[2] Geraldo Gil Ramundo Gomes, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, ge@inatel.br

The propagation coefficient is always greater o equal to one, but for a wave propagating in the air, this coefficient is just a fraction greater than one. Thus, there is another parameter to study a wave propagating in the air, called refractivity (***N***), that is the number of parts per million that exceeds the unity, as shown by (2) [1].

$$N = (n-1) \cdot 10^6 \quad (2)$$

The refractivity ratio, for digital radio links up to 10GHz, can be obtained by (3).

$$N = 77.6 \cdot \frac{P}{T} \cdot 3.732 \cdot 10^5 \cdot \frac{e}{T^2} \quad (3)$$

Where P is the dry atmosphere pressure in *mbar*, T is the absolute temperature in *Kelvin* and e is the water vapor pressure in *mbar*.

The value of N varies with the altitude because of the pressure and of the temperature. The pressure and the humidity usually decrease exponentially with the altitude, while the temperature decreases linearly. The typical values of refractivity ratio are between 200 and 500. In general, the refractivity decreases exponentially with the altitude, in a normalized atmosphere, as shown in (4).

$$N(h) = N_0 \cdot \exp(-0.136 \cdot h) \quad (4)$$

Where h is the altitude in *Km.*

The absolute value of the refractivity ratio is not important to study the degradations introduced by the troposphere in a digital radio link but the variations of this parameter can change the trajectory of an electromagnetic wave. Thus, it is important to define the refractivity gradient (G), as shown in (5).

$$G = \frac{dN}{dh} \quad (5)$$

For a homogenous atmosphere, the value of this parameter is a constant. When the atmosphere varies with time, the refractivity gradient also varies, which affects the propagation conditions. Because of this, the trajectory described by an electromagnetic wave propagating in the troposphere is not a straight line, but a curve. The radius of this curvature (ρ) depends on the refractivity gradient and can be described by (6).

$$\frac{1}{\rho} \cong -\frac{dN}{dh} \quad (6)$$

In addition, it is important to note that the Earth does not have a flat superficies, but it can be represented as a curvature with radius a that is equal to 6371Km. Thus, a precisely analysis of the line of sight between two antennas must consider the relative distance between the two curvatures. To facilitate this analysis, one may consider that the wave propagation trajectory is a straight line and the curvature of the Earth is modified by the refractivity of the medium. The new curvature of the Earth is defined as effective radium of the Earth (R_e). The effective radium is defined as the hypothetical radium of a spherical Earth without atmosphere, where the propagation of electromagnetic waves is described by a straight line. The effective radium of the Earth can be calculated by (7).

$$R_e = k \cdot a \quad (7)$$

Where k is the effective radium factor or k factor. The relationship between the Earth radium and the propagation trajectory can be obtained by (8).

$$\frac{1}{k \cdot a} = \frac{1}{a} - \frac{1}{\rho} = \frac{1}{R_e} \quad (8)$$

Thus, the k factor can be defined using the refractivity coefficient by (9).

$$k = \frac{1}{1 + a \cdot \frac{dN}{dh} \cdot 10^{-6}} \quad (9)$$

The value of k is usually between 1 and 2, depending on the weather of the region. The reference value of the refractivity coefficient is –40, which results in ρ=4a, which is defined as standard atmosphere. In this case, the value of k can be obtained by (10).

$$\frac{1}{k \cdot a} = \frac{1}{a} - \frac{1}{4 \cdot a} = \frac{3}{4 \cdot a} \therefore k = \frac{4}{3} \quad (10)$$

SIMULATIONS

The simulator presented in this paper has been developed to show to the user how the k factor can interfere in digital radio links. The user provides the frequency of the electromagnetic wave, the antennas heights and the k factor. The relief of the digital radio link must also be provided by a .DAT archive with the heights of the relief points. The distance between these points must also be provided. Figure 3 shows the program main window.

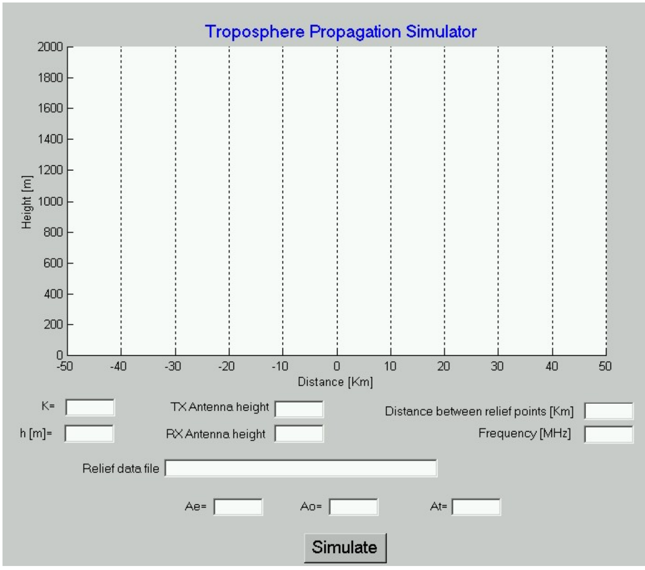

FIGURE 3
SIMULATOR MAIN WINDOW.

The parameters *Ae*, *Ao* and *At* are, respectively, the free space, the obstacle and the total attenuation. The free space attenuation is obtained by (11).

$$A_e = 32.44 + 20\log(f) + 20\log(d) \tag{11}$$

Where *f* is the signal frequency in MHz and *d* is the distance between the antennas in Km.

The knife cum model is used to define the obstacle attenuation. In this model, the obstacle attenuation can be calculated using the empiric formula given by (12).

$$A_o = \begin{cases} 0 & v \leq -1 \\ -20\log(0.5 - 0.62v) & -1 < v \leq 0 \\ -20\log\left(0.5e^{-0.95v}\right) & 0 < v \leq 1 \\ -20\log\left(0.4 - \sqrt{0.1184 - (0.38 - 0.1v)^2}\right) & 1 < v \leq 2.4 \\ -20\log\left(\dfrac{0.225}{v}\right) & v > 2.4 \end{cases} \tag{12}$$

Where *v* is the Fresnell-Kirchoff coefficient. This coefficient defines if the obstacle has affected the first Fresnell ellipsoid and it can be calculated based on the geometry of the link, as shown in Figure 4.

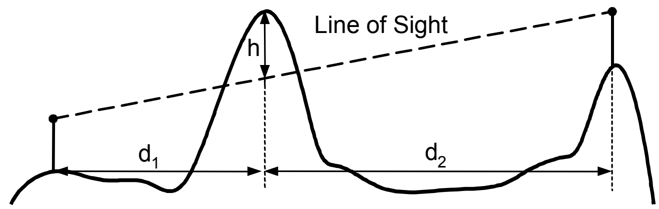

FIGURE 4
GEOMETRY OF A LINK

Finally, the Fresnell-Kirchoff coefficient can be obtained by (13).

$$v = h \cdot \sqrt{\frac{2 \cdot (d_1 + d_2)}{\lambda \cdot d_1 \cdot d_2}} \tag{13}$$

Where λ is the wavelength of the transmitted signal.

It is important to note that the height *h* may vary with the *k* factor. Figure 5 shows the simulation results obtained with a very high value of *k* (without atmosphere).

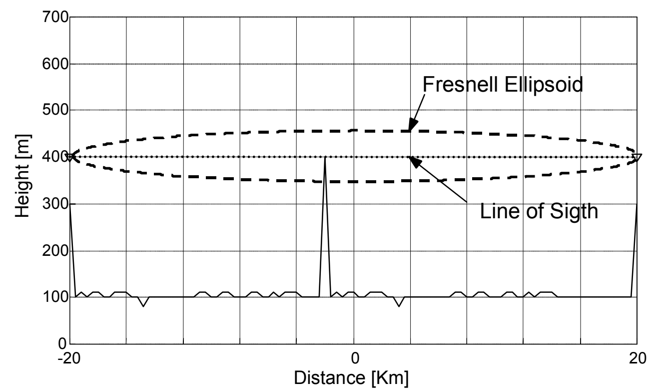

FIGURE 5
DIGITAL RADIO LINK WITHOUT ATMOSPHERE.

The results presented in Figure 5 have been obtained with a 1GHz electromagnetic wave. The free space attenuation is 244.37dB and the obstacle attenuation is 6dB. But, as showed in the previous section, the refraction in the atmosphere causes a curve trajectory in the waveform propagation. Readjusting the Earth curvature can compensate this trajectory. Figure 6 presents the results for the same simulation above, but with the standard atmosphere (*k*=4/3).

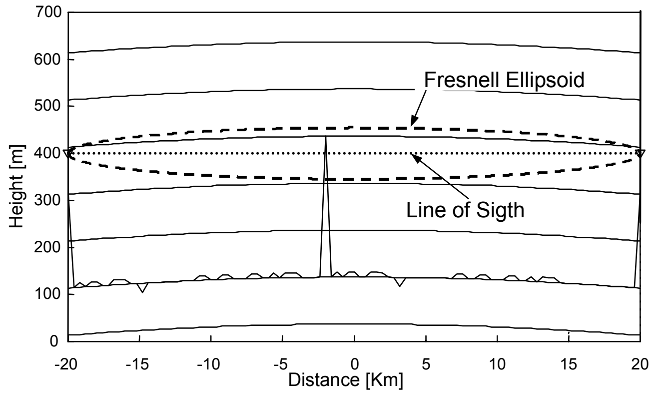

FIGURE 6
DIGITAL RADIO LINK IN A STANDARD ATMOSPHERE.

It is possible to note that the obstacle is, actually, above of the line of sight and the obstacle attenuation is, therefore, 13.14dB.

There are special conditions where the *k* factor is negative. In this case, the correction of the Earth curvature may reduce the obstacle attenuation, as can be seen in Figure 7. This result has been obtained with the same parameter used in the others simulations, but with k = -0.8. The obstacle attenuation is 0dB because the obstacle does not interfere in the first Fresnell Ellipsoid.

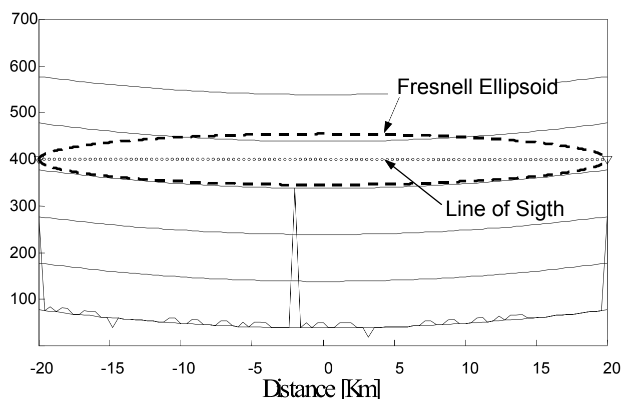

FIGURE 7
DIGITAL RADIO LINK IN ANOMALOUS CONDITIONS.

CONCLUSIONS

The propagation of electromagnetic waves is a very important issue in Telecommunication Engineering and must be presented clearly to the students. In this paper, a computer tool to simulate and analyze digital links has been presented with some commented results. With this tool, the student can visualize the effects of the different parameters in the link, as frequency, *k* factor and relief, which facilitates the apprenticeship of the issue.

A ROBUST SPEECH RECOGNITION SYSTEM FOR CAR ENVIRONMENT

Francisco J. Fraga[1], André G. Chiovato[2] and Rodrigo B. Brito[3]

Abstract *— This paper presents a robust speech recognition system designed for the car environment. It was developed in an undergraduate research project and we carried it out in two steps. First, a specific database was designed for this speech recognition task. In the second step, an Automatic Speech Recognition (ASR) system was designed using HTK®, a software tool which is worldwide used in the development of HMM-based (HMM: Hidden Markov Models) ASR systems. We performed two experiences at different settings of training and test. In the first experience, the test conditions were matched exactly to the training conditions, and a recognition rate of 99.88% was achieved. In the second experience, using signals with high SNR for training and signals with low SNR for test, 99.16% of the total test utterances were correctly recognized. These results motivated the undergraduate students in continuing the research towards the implementation of a robust and low-cost ASR system for car environment.*

Index Terms — Robust speech recognition, Hidden Markov Models, car noise.

INTRODUCTION

The robustness of an automatic speech recognition system is strongly influenced by the capability to handle the presence of background additive noise and to deal with the distortion caused by the frequency response of the transmission channel (additive and convolutional noise).

Among the distortions caused by the environment we can include: limited bandwidth of the transmission channel, channel distortion caused by non-linear phase transfer functions, cross talk and echo [1]. These are some of the problems we have to face when treating with real-life scenarios in automatic speech recognition.

Furthermore, it is well known that in noisy environments the speaker increases the vocal effort to overcome the noise, causing a speech distortion called *Lombard effect* [2]. Other effect that changes the speaker's voice is the high gravitational acceleration when the pilot pronounces a word command in the cockpit of an aircraft [2].

In the recent past, several speech recognition systems achieved good performance working in laboratory environment, but failed dramatically when tested in real-life scenarios [1]. In order to improve the recognition rate, modern systems realize an appropriate extraction of robust features to represent speech patterns and/or match the training and test conditions to the same real-life situations. During the last years, an increasing number of researches were publicized on these topics, reflecting the importance of these issues.

This paper presents a robust speech recognition system for working in a real-life scenario that is the car environment, an application with good commercial acceptance and a real challenge for current available speech recognition algorithms.

Speech captured in a running car is perturbed by noise from engine and tires, from wind, rain and traffic. With a microphone placed 50 cm away from the mouth of the speaker, the resulting captured signal may exhibit a negative signal-to-noise ratio (SNR) in decibels [3].

The speech recognition for controlling the car functions (such as headlight, windows, lock and others) is an application we are currently working on in an undergraduate research project of the Digital Signal Processing Research Group from Inatel. This is a typical situation that is extremely appealing for an ASR application.

When a person is driving a car, his or her eyes and hands are entirely occupied on this task and the manual control over any car function can cause distraction in traffic. The use of the own voice for command the car functions could avoid this problem. Other interesting use of an ASR system is in long trips, especially during the night, when the voice control over the headlights (full beam, low beam) can diminish the possibility of an accident caused by sleeping.

In order to develop an ASR system for this application, we have divided the job in two steps. First of all we have done several speech recordings to build an organized speech database for training the speech models, a mandatory requirement for any ASR system. After that we have designed the system itself, using HTK® (*Hidden Markov Models Toolkit*), a computer tool worldwide used for developing HMM-based ASR systems.

THE SPEECH DATABASE

With the aim of developing an ASR system for the car environment, we built a specific speech database, which was composed by utterances from two male speakers. They recorded his voices when were driving a car under various conditions: in streets and roads at different speeds (35 and 80 km/h), with and without traffic noise, with asphalt or stone pavement and with the car windows opened or closed. Two microphones simultaneously recorded the speech signal; both were about 50 cm away from the driver's mouth. One microphone was placed on

[1] Francisco José Fraga, Inatel - Instituto Nacional of Telecomunicações, Santa Rita do Sapucaí , MG, Brazil, fraga@inatel.br
[2] André Godoi Chiovato, Inatel, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí , MG, Brazil, andregc@inatel.br
[3] Rodrigo Barbosa Brito, Inatel, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí , MG, Brazil, rbarbosa@inatel.br

the car panel (at the same level of the steering wheel) and the other was placed near the car ceiling (this second microphone had poor quality, it costs five times less than the first one). The vocabulary contained about 50 isolated words, each of them was pronounced three times by the speakers in each recording condition. The final speech database had over 10,000 utterances.

The microphones used were: *Super Directional Desktop Microphone – M60* e *Handheld Recorder Microphone – M10* (the cheaper one), from *Telex Communications®* company, which illustrations can be viewed in figures 1 and 2. The speech recording was done by means of a portable Digital Audio Tape (DAT), model *TCD-D100* from *Sony®* company, as illustrated in figure 3. Figure 4 shows the recording scenario, which is the interior of a car from *Fiat®* company, model *Pálio 1.6 16 V*. In this figure we can see the microphones connected to the DAT through two audio cables.

After recorded by the DAT, the speech signals were transferred to a computer where they were separated and titled according to the vocabulary word, the utterance (if it was the first, second or third repetition of each word), the speaker and the recording conditions, as the example showed below:

TemperaturaInterna2_André_Av_Ab.wav

It means that the speaker *André* recorded the Portuguese word command *TemperaturaInterna* for the *2nd* time at the main *Av*enue with opened windows (the car windows were "*Ab*ertos" as we say in Portuguese)

The final recorded speech database consists of 5.344 files (.wav). In order to perform this task, we have to pronounce the word commands while driving the car in roads and streets for 266 km .

THE ASR SYSTEM

In the second step of our undergraduate research project we have designed an ASR system using some tools of the HTK® software.

In the front-end stage, we have extracted 12 mel-cepstral coefficients from speech frames with 30 ms duration and an overlapp of 33%, which leads us to a frame rate of 100 Hz. For each utterance, the mean of the mel-cepstral coefficients were computed over all frames and then were subtracted from the coefficients vector with the aim of neutralize the channel distortion [2].

In order to form the observation vector, the first and second time derivatives were added to the end of the 12 mel-cepstral coefficients vector.

A single left-right HMM was used for modeling each vocabulary word. The number of states of each model was variable according to the number of phonemes of the vocabulary words.

Five gaussian mixtures with diagonal covariance matrix were used to estimate the acoustic emission of each state of the HMM's.

The models were trained with a third part of the utterances; the remained utterances were used to evaluate the system performance.

Two experiences were carried out: In the first one, the test conditions were matched exactly to the training conditions, which is the ideal way of developing a robust ASR system, although it is difficult to realize in a real-life application [4].

The performance achieved with this set up, in terms of correct word recognition rate, was **99,88%.**

The second experience was carried out at just the opposite situation: the utterances used for training were the best ones (high SNR) and those used for test were the worst ones (low SNR). Although running at these adverse conditions, **99.16%** of the total test utterances were correctly recognized.

CONCLUSIONS

We conclude that these good results were achieved because we extracted robust features from the speech signal (mel-cepstral coefficients with mean cepstral subtraction). We observed also that the same performance was achieved by the two microphones. This fact leads us to the conclusion that the distortion caused by the cheap microphone was neutralized by the robust feature extraction scheme.

The speech database will serve also for other research projects involving robust speech recognition and speech enhancement.

Finally, we want to remark that the students that worked in this undergraduate research project became enthusiasts of the speech recognition area and both have already started his master level studies in speech processing.

ACKNOWLEDGMENT

We sincerely thank for the help of Prof. Carlos A. Ynoguti and for the funding of FINATEL and FAPEMIG .

INTERACTIVE CHAT: AN EXPERIENCE IN A VIRTUAL ASSESSMENT

Luciana A M Zaina[1,2], Graça Bressan[3] and Wilson V Ruggiero[4]

Abstract — *The increase of distance education in the world has been a reality in universities and companies encouraging researchers to create ways to keep track of the virtual classes. And at a distance it is very important to have ways to provide interaction between the teacher and the students, because there is no physical contact in a distance system environment. The integration activities might be used not only in distance classes, but in traditional classes too. This work has been presented a methodology to plan and to handle educational chats and how to evaluate the students in these events. The methodology was applied, by the teacher Luciana Zaina, to a group of learners from the Computer Engineering course at the Engineering College of Sorocaba aiming to discuss a practical application of the Deterministic Finite Automata Theory.*

Index Terms — *chat, classroom support, interactive tool, virtual discussion, virtual learner assessment.*

INTRODUCTION

Using a synchronous tool such as chat allows the students to develop new syntheses, analysis and evaluation abilities, because it forces the students to write what they know, their ideas and to give solutions to problems proposed by the teacher.

The chat discussion gives the students the opportunity to develop a critical sense development but this is not the only point. The synthesis process is essential to make the students able to expose their points of view more clearly allowing the teacher to track of the student's performance along the course. And it can be used as an environment to eliminate learner doubts or as a way to introduce new challenges to the students, making the classes more dynamic [5],[9].

The chat may be a good option when the teacher wishes to make questions and to have immediate answers from the students, because they can exercise their ability to come to a conclusion fast. The chat is applied to situations when the teacher needs to check if the student has assimilated the concepts and if he knows how to use the topic studied developing the synthesis, analysis and evaluation abilities in the learner. The chat discussion is a good experience for many students because they may feel more comfortable to show their opinions, they don't need to stay face to face with other students, they are not be afraid to present their ideas to other persons.

METHODOLOGY TO EVALUATION

The methodology propose in this work to evatuate the student in a chat event is composed by the points that are presented in this session.

Event Planning

Before the chat assessment event the teacher must plan how he/she will conduct the discussion and how he/she will validate the knowledge process checked in the chat. The teacher should define the discussion goal and inform the learners of the expected result at the end of the event in order not to lose the focus of the discussion. Getting an objective discussion is essential to define the questions or themes that will be made to the students, questions that encourage student's reflection about the theme, but the teacher should be prepared to ask new questions during the event if the bypass is interesting and if it doesn't damage the discussion focus [1],[7],[9].

The discussion should stimulate the student to organize his ideas and to express his conclusion about a question or about another student's opinion, constructing an interesting knowledge network. The teacher make use of questions that analyze a topic deeply such as "what do you think about...?" or "do you agree or disagree with...?". Table I presents some question suggestions to be used in a chat event [1],[9].

TABLE I
QUESTION SUGGESTIONS TO BE USED IN THE ON-LINE ASSESSMENT [1] APUD SAVAGE

Questions
Why did the author use this statement ?
Do you agree/disagree with this point of view ?
What do you think about... ?
Can you explain this statement better ?
How do you compare topic A and B ?
Why did you use this statement ?
Doesn't what you are saying now contradict what has been said before?

[1] Luciana A M Zaina, University of São Paulo, Computer Engineering, Brazil, lzaina@larc.usp.br
[2] Faculdade de Engenharia de Sorocaba, Brazil, luciana@facens.br
[3] Graça Bressan, University of São Paulo, Computer Engineering, Brazil, gbresan@larc.usp.br
[4] Wilson V Ruggiero, University of São Paulo, Computer Engineering, Brazil, wilson@larc.usp.br

The planning must approach all the concepts of the theme, without being rigid, because unplanned topics may come up and they might be interesting for the discussion. In these cases, the teacher should redirect the discussion without losing its main goal and come back to the point where the discussion was interrupted [9] as it is shown in Figure 1.

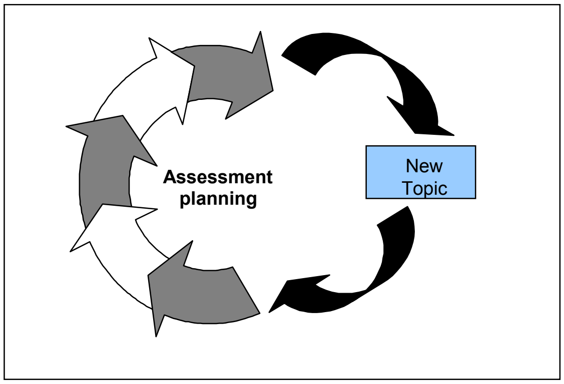

FIGURE. 1
THE CHAT EVENT MAY HAVE NEW TOPICS TO BE DISCUSSED

The teacher must determine a deadline for the discussion so that it doesn't remain unfinished. It is important to plan how much time the participants will spend talking about a topic, although this can be changed during the event if it is important for the discussion. The moment the group finds the solution for the problem is another way to establish the end of the discussion, but it is fundamental that all the participants agree with the solution and conclude the discussion [7]. Table II presents a suggestion to track the chat event.

TABLE II
ASSESSMENT PLANNING

ASSESSMENT VIRTUAL PLANNING

Result:			

The student should be oriented to identify himself in the beginning of the chat session helping the teacher to know who exactly is talking at the moment [2]. The chat tool can implement ways for the teacher to recognize the students through the user login or photos which are stored in the tool's database. Besides this, the teacher must highlight the use of netiquette*(*etiquette used among the participants of a virtual event*)* avoiding the sending of rude messages among the chat participants [9].

The teacher must plan how to guide the virtual session and he should present this plan to the students before the beginning of the event, emphasizing the following points:

- **Discussion main goal:** the student must be aware that he is the center of the discussion and not the teacher. The learner may conclude a discussion topic, he doesn't need to wait for the teacher's conclusion.
- **Respect for the other participants' opinion:** the student may be critical, but he cannot disrespect another participant. He can expose his opinion without arguing with the colleague, exercising his ability to explain his point of view about a theme [5].
- **Controversy themes:** the learners may disagree with the others opinion but they cannot ridicule the other participant's ideas, because this might cause an embarrassing situation and the students may be afraid to show this opinion again [7].
- **Add new knowledge to the discussion:** answers like "I agree" or "I disagree" add nothing to the discussion. The students should feel motivated to explain why he agrees or disagrees with a subject, giving new values to the discussion. The learner may come to a good conclusion and a good explanation without adding different ideas to the discussion [1].
- **Interruptions during the discussion:** a participant cannot interrupt another participant's explanation. When the student wishes to express his opinion about a topic, he must wait for his colleague's conclusion and he might ask the teacher if he can talk his ideas about the topic. The teacher must use ways to control the time of each student in order to avoid having all the participants sending messages at the same time [5],[7].

Assessment Applying

After the planning, the teacher should schedule the day and hour of the event and expose to the students the real aim and what results he/she wishes to achieve, indicating the way that the learners should follow during the chat. This is the same as determining the assessment content.

The chat is an efficient tool when all the students have the opportunity to exchange their ideas and it may become chaotic if there are a lot of people “speaking” at the same time. Thus, it is ideal to create chat groups from five to seven learners and to put these groups in different rooms mainly when there are a lot of students in the class [3]. This way the teacher can handle the discussion more easily, avoiding difficult situations where only some students show their opinions.

Technological problems such as connection failures may cause participants not to feel motivated and the teacher must avoid these situations by checking the chat environment where the discussion will occur before the event to start. The student must feel that he is contributing to the discussion, he must feel he is improving his skills about the subject and this kind of problem may be a critical issue [4].

The teacher should provide the group integration, in the beginning of the chat, reminding them of the discussion important points: respect between the participants concerning different viewpoints, the discussion goal and the importance of the students' participation to the success of the event. Afterwards, the discussion can start according the teacher planning [9].

It is very important for the teacher to observe if there are students monopolizing the discussion, because some may be shy and not show their ideas. The isolated students should be invited to talk about their opinion and the teacher might use sentences like: "Bob, what do you think about Susan's statement ?". In case of problems with the learner's behavior, the teacher must send private messages to him referring to use of impolite language without exposing him to the other chat participants. The incentive to the students is necessary for the discussion and they may feel that their contribution is valuable [1],[2],[3].

The teacher must decide what will be the ideal topic to be discussed at first in case of message collision, when two different learners send different messages at the same time, but the teacher cannot forget that the second message can be discussed later. The teacher may use a way, as a token pass for instance, to organize the order of each participant's talk and he determine to the students the order of the token will pass to the students.

Confirming a student's statement should always be used when his explanation is not clear and the teacher may use questions to force the learner to explain his point of view better and in more details [8].

Divergent ideas must be extensively discussed during the event, but the participants cannot forget to be always respectful to one another. It is worth forcing the students to discuss different ideas and come to an agreement, about a topic exercising their critic thinking and their ability to synthesize their opinions.

Analising and Mensuring Assessment

The chat evaluation is not an easy task, as in any kind of discursive test, but if the teacher plans the virtual event before applying it he will spend less time correcting the assessment.

Analyzing the chat event result is difficult for two reasons. The first one is that a lot of information needs to be checked. Besides, as the ideas were expressed without a sequence during the chat, the teacher must reorganize the content in order to correct it. The teacher must check the chat log to have a concrete result of the assessment, because it is impossible to obtain an accurate measurement when the chat finishes. A premature evaluation may lead to a mistake when giving the student's grade [8].

It is ideal that the teacher control the discussion using a table, so that he can verify the essential points in each theme. The loss of focus must be handled by the teacher and the teacher should consider this in his evaluation. The teacher must check the development of analysis, synthesis and evaluation skills and be concerned with the truth of student's statement, checking if what he said makes sense.

The teacher should determine the weight of the questions or themes that will be used in the assessment and at the end of the event, to measure the student contribuition in important points.

The teacher should present the event result to the chat participants to give them the opportunity to evaluate their flaws as well as the correct conclusions of each student. The learner can verify his correct and incorrect statements, the difficulties he had to express his ideas and he can decide which direction he should take [2],[7].

The final result can provide the teacher with valuable information, helping him analyze the event planning. This way, he can check if he needs to change his strategy when conducting and planning the discussion.

THE STUDENTS' EXPERIENCE

Based on the proposed methodology, a virtual event was planned and applied as an alternative way to evaluate the students of an engineering course in the Deterministic Finite Automata Theory syllabus. The main goal was to demonstrate that this theory can be applied in the development of real systems.

"A System for Web Based Instruction Using Sequential Automata" was the article chosen to be analyzed and discussed, which approaches the Mealy and Moore Automata used to model the Web courses. The article emphasizing that the best organization of material and the hypermedia documents provide facilities of the maintenance and reuse of the course content through automata implementation, eliminating the redundancy of the material [6].

Planning

First, the event was carefully planned concerning in the main points such as discussion goal, the themes that will be discussed, what is important to observe about the student's opinions and the expected result. The discussion goal was "Analysis of the automata applications to systems development in the Web", focusing on the programs functionality modeled by automata. The teacher thought the article content was very important to the discussion goal.

According to the article the student must show the teacher that he understands how the theory can be applied to practice. Bringing the knowledge learned in the class to the application described in the article the student develops synthesis skills, because he will make a connection between conception and practice. The event was planned based on the article and it is showed in the Table III.

TABLE III

THE EVENT PLANNING

VIRTUAL ASSESSMENT PLANNING			
Goal: discuss the relation between the automata theory and a practical application of it in a Web system		**Total discussion time:** 1 hour	
Start date: 09/11/2001 - 2:00 pm		**Finish date:** 09/11/2001 - 3:00 pm	
No.	**Question**	**Discussion Time**	**Doubts/ New Questions**
1	Based on the article, do you think the finite automata is ideal to develop Web programs using the hypermedia conception ?	10 minutes	
2	How are the Mealy and Moore Machines used in the model presented in the article ?	10 minutes	
3	How can the non-determinism automata be used to model a Web course ?	15 minutes	
4	How can the finite automata be applied to model the study personalization ?	15 minutes	
The result: The students understood the relation between theory and practice.			

Discussion Handling

Before the event the teacher talked to the students about the essential points for conducting a successful discussion. According to the methodology the teacher highlighted the important topics of the discussion to learners [9]:

- **The main object of the discussion:** the student cannot forget that he is the main object of the discussion. The teacher will interfere only in extreme situations.
- **The respect to other students' opinion:** the student must be careful when criticizing another learner's point of view. He must stimulate the students to participate in the event, and at the same time, keep unpleasant comments and jokes to themselves.
- **Add knowledge to the discussion:** remind the students that they should express their opinions through clear ideas, adding new values to the discussion.
- **Interruptions:** the teacher will use a virtual token to control who is talking in a determinate moment preventing the student to be interrupted by another learner. The token will be passed to the student when he wishes to say something and it must be returned to the teacher after a student finishes exposing his opinion and then the teacher will decide who is the next learner to talk.

By adopting a process to control the time that each one can talk, it was possible to prevent students from interfering in one another's explanation, mainly because the chat tool allows only text messages. The teacher used the token system, which determined who should express his opinions about a subject, and when somebody wished to talk they could ask for the token. Sometimes, it was worth breaking the normal procedure of the discussion to approach interesting topics such as the necessity to explain the relationship between hypermedia and automata according to the article.

The discussion elapsed normally and the number of interruptions was practically zero. Some students wished to expose their ideas and, because of this, sometimes asked for the token at the same time. The priority always given to whoever was talking and after he finished the teacher passed the token to another student that had requested it.

The major problem was the phone connection failure that caused the discussion to be interrupted three times. When we managed to connect again we had to restart the discussion point spending more time than necessary with the event. The time event estimate had an overload in the chat plan and part of this was caused by the connection problems.

The event started when planned and all the participants were in the chat room. The teacher welcomed everybody and started to make questions determining who was the first to answer it. All the time, the teacher passed the token to the student that she thought was the best one to expose his idea at the moment, and sometimes another participant asked for the token to explain his position about the topics. This kind of control prevented the shy student from standing only as an observer, encouraging him to explain his point of view.

During the event it was possible to observe that the students understood the article conceptions and they could relate the theory learned in the lectures to the work presented in the article. In general, they expressed their thoughts clearly and the teacher didn't need to make many interventions.

After one and half hour of discussion the teacher finished the event. He could not ask all the planned questions, because there were connection problems and it was necessary to explain some conceptions during the event. Besides these, the students' participation was higher than the teacher expected causing more time of discussion that had been planned.

Log Analysis

During the event the teacher must be concerned about conducting the discussion so she will analyze the results of the event by the log file comparing it with the event plan. Based on the questions made to the students, the weight of each question and the log chat, the teacher could conclude the real effect of the event. The Table IV shows how the teacher made the chat participants' evaluation.

TABLE IV
THE EVALUATION BASED ON THE ANALYSIS OF THE CHAT LOG

	Weight					
		1	1	1		3
	Participant	**Does he lose the discussion focus?**	**Does he add information?**	**Do his statements make sense?**	**Observations**	**Final Grade**
Question 1	Student A	1	1	1	He interrupted another student. He focused on the article.	3
	Student B	1	1	1	He asked me to explain a formal conception about hypermedia.	3
	Student C	1	1	1		3
	Student D	1	1	1		3
	Student E	1	1	1		3
Question 2	Student A	1	1	1	He explained the relation between the course content.	3
	Student B	1	1	1		3
	Student C	1	1	1	He made a technical explanation	3
	Student D	1	1	1	He asked me to compare the model to the distance learning.	3
	Student E	1	1	1		3
Question 3	Student A	1	1	1		3
	Student B	1	1	1		3
	Student C	1	1	1		3
	Student D	1	1	1		3
	Student E	1	1	1	He had doubts about the use of the non-determinism in the distance courses.	3

When analyzing the chat log it was possible for the teacher to verify the concrete result of the discussion. The student could get three points as a maximum grade which was divided in three sub topics and each one was worth one point. The topics available were:

- **Does the student miss the discussion focus?:** it was checked if the student didn't forget the real discussion goal.
- **Does the student add information?:** it was verified if the student understood the themes and if he related practise to theory.
- **Do his statements make sense?:** it was checked if the student said absurd statements.

The students had an active participation in the event and they didn't lose the main focus of the discussion. Sometimes the teacher had to explain some conceptions such as the formal definition of hypermedia, but this didn't disturb the event. On the contrary, it enriched the discussion with the participants conclusions. The target change was excellent to the discussion, but the trouble was to be attentive to bring students back to the break point and not to lose the real discussion objective, and this was controlled all the time when the students had doubts.

All the participants made sense in their affirmations adding valuable information to the theme. They provided the relationship between theory and practise showing their understanding about the automata finite application. Besides this, the teacher could observe that the students exposed the main article points, always associating it with the automata finite concepts.

During the event some expressions and sentences were split making it difficult for the teacher to make an immediate analysis. The chat log was fundamental to be sure of the student's contribution to the event, because the statements could be joined to the general context of the student's affirmations.

© 2003 ICECE

CONCLUSION

The teacher asked the learners to send e-mail messages expressing their opinion about the chat experience. They should especify what they had felt and what they thought about their participation in an educational assessment chat. They had to evaluate the following points:

- Did he find difficulty expressing his ideas?
- Did he feel comfortable to talk in a virtual event?
- How does he compare the assessment in a chat to the traditional evaluation form?

Studying the student's answers it was possible to conclude that all the participants thought that this kind of event was very important to their learning, but they highlighted positive and negative points. The positive points pointed by the students are:

- They need to express their ideas in a writing and in a virtual way, developing their capacity to be consistent and coherent in their explanation so as not to have a misinterpretation of their point of view. Normally people have difficulty writing their ideas, they prefer speaking to writing about something. This kind of event it is a great opportunity to develop this ability.
- The interaction between the participants during the test. It is very difficult to the students exchange information and ideas to construct a problem solution step by step in a traditional test in group. The synchronous event like a chat permits learners to reach a conclusion with all the participants ideas, building a network of information.

The students pointed as negative points:

- Although the students' interruptions didn't occur frequently in this event, some students caused interruptions when another had the token. The interruptions were controlled and they demonstrated the students' wish to participate in the discussion.
- The Internet disconnection interrupted the event three times. We had problems with the Internet connection during the event and the discussion had to restart when this problem occur.

The students' information showed us that a different way of work or assessment can motivate them. They emphasized in their answers that the event allowed them a better integration during the problem resolution.

We could conclude that planning an event is fundamental because it can avoid a lot of common problems and help the teacher to deal with difficult situations. Although problems will always exist, there are ways to minimize them. Showing the students the discussion goal and what is expected from them allows them to prepare and to study the event theme.

The number of times there is loss of focus in the discussion can be reduced through a well-handled event. The teacher must try to let learners feel relaxed and encourage them all the time to express their opinions about the theme.

The event evaluation must be done after the chat avoiding flaws in the analysis and allowing the teacher to check the truth of the students' messages. Besides this, the teacher may misunderstand a point of view and he can analyze the statement better through the chat log.

When the interactive tools like chat and forum are used in distance courses, they may be a way to get concrete data about the student's evolution in the course and, in some cases, to detect failure in the course material. The plan in a virtual discussion is a prerequisite to the success of the event, because an unplanned chat without a mediator will be chaotic.

The use of interactive chat to support a traditional class brings advantages to the teacher and to the students. The learners can improve their capacity of expressing their opinions and the teacher provides the students with different ways to discuss the syllabus, motivating them to study outside the classroom.

MÉTODOS EFICIENTES DE ENSINO DE ENGENHARIA: A FERRAMENTA COMPUTACIONAL DE SIMULAÇÃO COMO UM COMPLEMENTO NO ENSINO DE PRINCÍPIOS DE COMUNICAÇÃOES.

Flávia Mendonça Teixeira[1], *Luciano Leonel Mendes*[2]

Resumo *— O objetivo deste trabalho é mostrar como o método de ensino de engenharia pode ser melhorado através do uso de ferramentas computacionais de simulação. Procura-se introduzir a simulação computacional como ferramenta decisiva na aprendizagem rápida dos conceitos de princípios de comunicação.*

A metodologia consiste no desenvolvimento de um programa, utilizando a plataforma MatLab®, que fornece auxílio aos usuários na assimilação dos conceitos básicos de modulação. Este programa conta com duas interfaces gráficas: uma permite a entrada e visualização dos parâmetros necessários à modulação em amplitude e a outra permite a entrada e visualização dos parâmetros necessários à modulação em freqüência. São apresentados gráficos de todos os sinais envolvidos no domínio do tempo e da freqüência, possibilitando um método eficiente de ensino/aprendizagem através da análise e da comparação entre os vários sinais gerados.

INTRODUÇÃO

Um dos grandes desafios em cursos de base científica e tecnológica é acompanhar os avanços da ciência e da tecnologia sem deixar de lado o ensino de seus princípios básicos. Os avanços tecnológicos obtidos nas últimas décadas são surpreendentemente grandes e o número de tecnologias a serem estudas por alunos de graduação, é muito volumoso. O curso de engenharia elétrica com ênfase em telecomunicações caracteriza-se, dentre outras coisas, por seu aspecto dinâmico no que diz respeito ao ensino de novas tecnologias. Assim, os conceitos básicos da engenharia, por se tratarem de assuntos de extrema importância e por criarem condições que permitam a melhor compreensão das tecnologias emergentes, devem ser passados aos estudantes com muita clareza e consistência.

A disciplina de princípios de telecomunicações, existente na maioria dos cursos de engenharia elétrica com ênfase em telecomunicações, retrata de maneira clara a necessidade da implementação de um método dinâmico e eficiente de ensino/aprendizagem. As técnicas de modulação em amplitude (AM – *Amplitude Modulation*) e freqüência (FM – *Frequency Modulation*) [1], vistas dentro desta disciplina, fazem parte dos conceitos básicos de comunicação analógica sendo amplamente utilizadas nos atuais sistemas de radiodifusão comerciais.

Tanto a modulação em amplitude quanto a modulação em freqüência decorrem de fenômenos físicos que possuem um modelamento matemático conhecido. Entretanto, verifica-se a latente necessidade de visualização gráfica de todos os sinais envolvidos nestes processos bem como a implementação de ferramentas computacionais de simulação.

O uso de tais ferramentas torna-se imprescindível ao estudo dessas técnicas, pois permitem a visualização de todos os sinais envolvidos no processo de modulação nos domínios do tempo e da freqüência. Assim, um software de simulação, utilizando a plataforma MatLab® e desenvolvido para dinamizar o processo de ensino/aprendizagem na disciplina de princípios de comunicações será descrito ao longo deste artigo. Neste artigo, serão apresentadas metodologias, abordando sua metodologia de ensino dos programas desenvolvidos e exemplificando seu modo de operação para tornar a disciplina mais interessante.

O USO DA PLATAFORMA MATLAB®

Dentre uma gama de softwares de simulação existentes no mercado, o MatLab destaca-se por possibilitar a implementação de modelamentos matemáticos utilizados em diversas áreas da engenharia e da física.

O MatLab [2] [3]pode ser utilizado tanto como ferramenta de cálculo interativa quanto linguagem de programação científica. Entretanto, ele apresenta algumas vantagens que justificam sua predileção entre profissionais do meio acadêmico: simplicidade, rapidez de processamento e interface gráfica avançada para visualização e análise dos resultados. Todas as variáveis do MatLab são definidas de forma matricial, o que torna seu ambiente de trabalho ideal para resolver problemas de cálculos envolvendo matrizes e vetores. Logo, o desenvolvimento do software de simulação para princípios de comunicação, que será descrito neste artigo, utilizou-se de todas recursos oferecidos pelo MatLab, como o uso de vetores, funções predefinidas e principalmente o uso das interfaces gráficas tanto para que o usuário possa organizar os parâmetros de entrada quanto para visualizar os efeitos destes parâmetros na modulação escolhida.

SIMULAÇÃO DE MODULAÇÕES AM E FM

[1] Flávia Mendonça Teixeira, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, flavia_mendonca@inatel.br
[2] Luciano Leonel Mendes, INATEL, Av. João de Camargo, 510, 37540-000, Santa Rita do Sapucaí, MG, Brazil, lucianol@inatel.br

O software para simulação de modulações em amplitude e freqüência foi dividido em dois módulos: um para modulação em amplitude e outro para modulação em freqüência.

Com o objetivo de estimular a interação entre aluno e software, foram criadas interfaces gráficas para organizar as informações a serem processadas, isto é, o usuário tem a possibilidade de visualizar todos os parâmetros e sinais escolhidos antes de iniciar o processo de simulação.

No caso da interface gráfica para o módulo de AM, pode-se definir a amplitude, a freqüência e a fase da portadora e do sinal modulante, sendo que este também pode ser definido como um sinal senoidal, quadrado, triangular ou aleatório.

Os sinais a serem processados são mostrados na tela, juntamente com os valores de índice de modulação e potências do sinal modulado AM-DSB e AM-DSB/SC. A Figura 1 a seguir ilustra a interface gráfica do software para o módulo de modulação em amplitude.

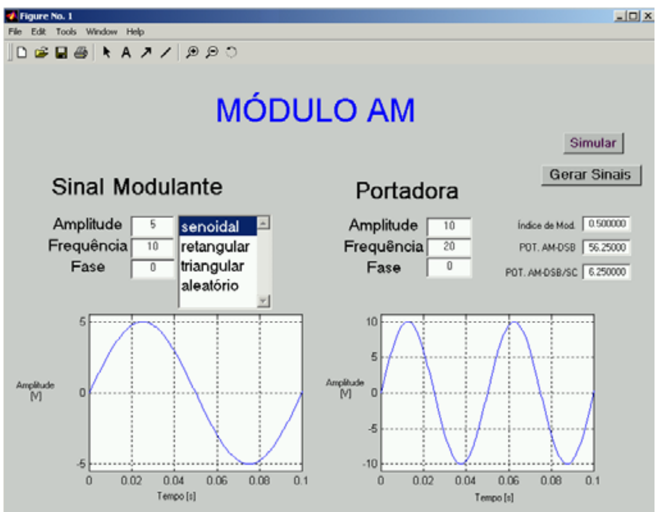

FIGURA. 1
INTERFACE GRÁFICA PARA SIMULAÇÃO DE MODULAÇÃO EM AMPLITUDE.

A interface gráfica do módulo para simulação de modulação em freqüência possui basicamente as mesmas características do módulo AM, sendo que a diferença é marcada pela necessidade do valor do desvio de freqüência como parâmetro para realizar a simulação.

No módulo FM, a interface gráfica, ilustrada a seguir, retorna os valores de índice de modulação e potência dos sinais modulados.

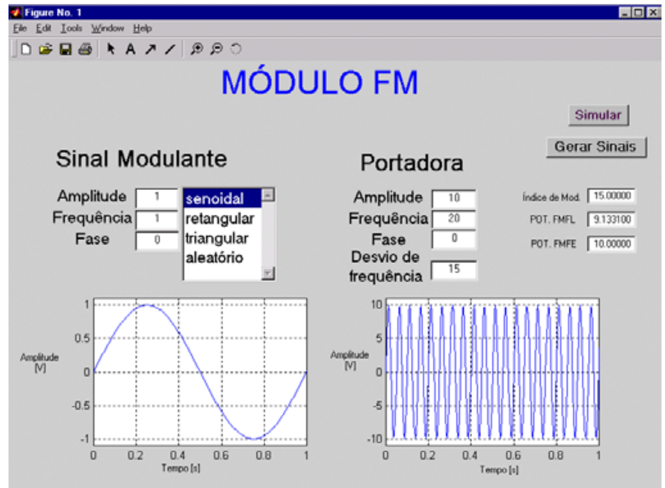

FIGURA. 2
INTERFACE GRÁFICA PARA SIMULAÇÃO DE MODULAÇÃO EM FREQÜÊNCIA.

SIMULANDO MODULAÇÕES EM AMPLITUDE

Para realizar a simulação de modulação em amplitude é necessário que todos os parâmetros de entrada da interface gráfica estejam devidamente preenchidos, isto é, o sinal modulante e a portadora devem ser predefinidos pelo usuário.

Como ilustração para o processo de simulação, tomemos como exemplo uma modulação AM gerada por um sinal modulante senoidal, descrito por (1) [1].

$$f(t) = A\cos\omega_m t \qquad (1)$$

Onde A é a sua amplitude e ω_m é a sua freqüência angular. Os valores adotados para a simulação foram, respectivamente, 5V e 20πrad/s. A portadora senoidal possui amplitude a e freqüência angular ω_o, cujos valores adotados para a simulação foram, respectivamente, 10V e 200πrad/s. Assim, a portadora pode ser expressa por (2).

$$c(t) = a\cos\omega_o t \qquad (2)$$

Os gráficos resultantes do sinal AM/DSB ficam descritos nos domínios do tempo e da freqüência conforme definido, respectivamente, por (3) e (4).

$$s(t) = [A + a\cos\omega_o t]\, sen\,\omega_m t \qquad (3)$$

$$S(f) = \Im[s(t)] \qquad (4)$$

A Figura 3 apresenta o sinal AM/DSB gerado pelo simulador, no domínio do tempo, enquanto a Figura 4 apresenta este sinal modulado no domínio da freqüência.

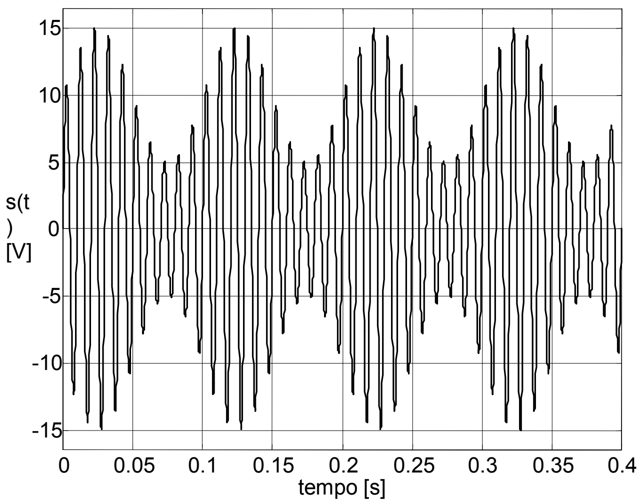

FIGURA. 3
SINAL AM/DSB NO DOMÍNIO DO TEMPO

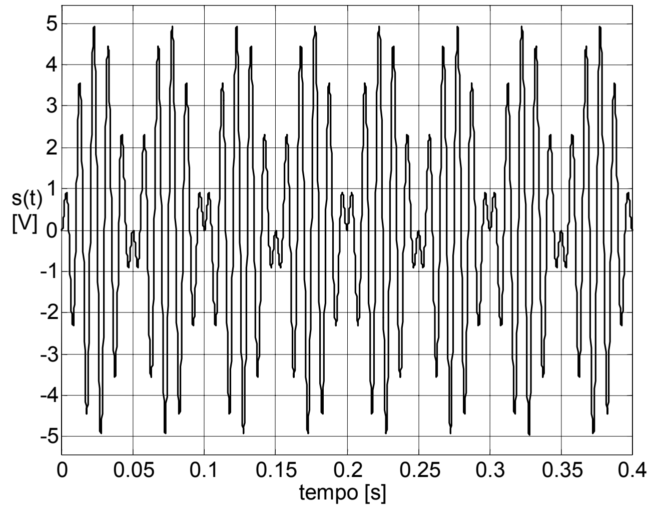

FIGURA. 5
SINAL AM/DSB-SC NO DOMÍNIO DO TEMPO.

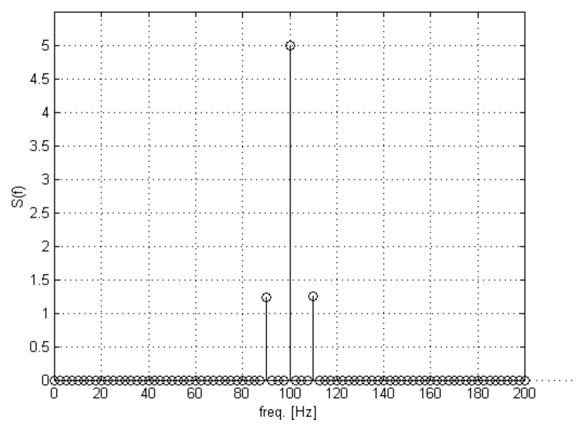

FIGURA.4
SINAL AM/DSB NO DOMÍNIO DA FREQÜÊNCIA

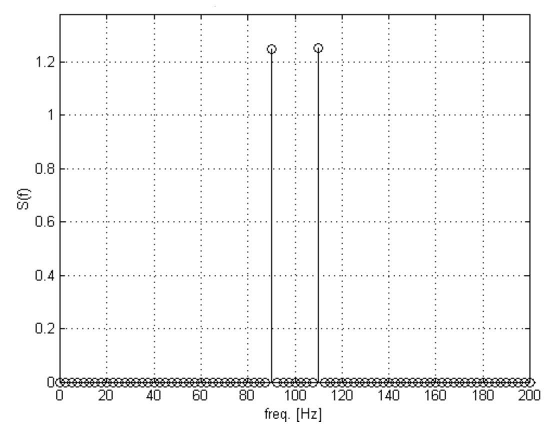

FIGURA. 6
SINAL AM/DSB-SC NO DOMÍNIO DA FREQÜÊNCIA

O simulador também gera o sinal AM/DSB-SC (*Amplitude Modulation – Doble Side Band with Supressed Carrier*), que é definido no domínio do tempo por (5) e no domínio da freqüência por (6).

$$s(t) = a\cos\omega_o t \times \operatorname{sen}\omega_m t \qquad (5)$$

$$S(f) = \Im[s(t)]\,. \qquad (6)$$

Nota-se que nesta técnica, a portadora não está presente no sinal modulado. Isto pode ser visualizado no domínio do tempo através da Figura 5, e no domínio da freqüência, através da Figura 6.

SIMULANDO MODULAÇÕES EM FREQÜÊNCIA

Para realizar a simulação de modulação em freqüência é preciso fornecer à interface gráfica do módulo FM os parâmetros que definem o sinal modulante, a portadora e também o desvio de freqüência, definido por $\Delta\omega$.

Para ilustrar o processo de simulação, considere um desvio de freqüência igual a 30πrad/s e um sinal modulante senoidal descrito por (7) [1].

$$f(t) = A\cos\omega_m t \qquad (7)$$

Onde A é a sua amplitude e ω_m é a sua freqüência angular, com valores de 1V e 2πrad/s respectivamente. A portadora possui amplitude (a) de 10V com freqüência angular (ω_o) de 40πrad/s, cuja expressão é dada por (8)

$$c(t) = a\cos\omega_o t\,.$$

8)

Desde modo, pode-se obter o sinal FMFL (FM Faixa Larga) utilizando a expressão apresentada em (9).

$$s(t) = a\,cos\left[\omega_o t + \frac{\Delta\omega}{\omega_m} sen(\omega_m t)\right]. \qquad 9)$$

Onde $\Delta\omega$ é o desvio de freqüência do sistema FM.
O sinal FM contém um número infinito de harmônicos em seu espectro, o que acarretaria para sua transmissão a necessidade de canal com largura de faixa infinita. Na prática, no entanto, pode-se limitar a faixa de transmissão do sinal FM a um valor finito, pois os harmônicos com freqüências acima de um limiar apresentam uma contribuição desprezível para a composição do sinal.

O gráfico do espectro de freqüências do sinal FMFL teve sua largura de faixa limitada, pelo simulador, a partir da regra de Carson, isto é, o espectro do sinal terá componentes harmônicas nas freqüências apresentadas em (10).

$$\omega_n = (\omega_o \pm n\omega_m), \quad n = 1,2,...,n_\alpha \qquad (10)$$
$$n_\alpha = (\Delta\omega/\omega_m) + 1$$

As amplitudes de cada componente espectral é definida por (11).

$$A_n = J_N(\Delta\omega/\omega_m)a \qquad (11)$$

Onde $J_N(\Delta\omega/\omega_m)$ é a função de Bessel de primeira espécie, com argumento $\Delta\omega/\omega_m$ e ordem N, com N variando entre $-n_\alpha$ e $+n_\alpha$.

A Figura 7 mostra o sinal modulado no domínio do tempo, enquanto que a Figura 8 mostra o sinal modulado no domínio da freqüência.

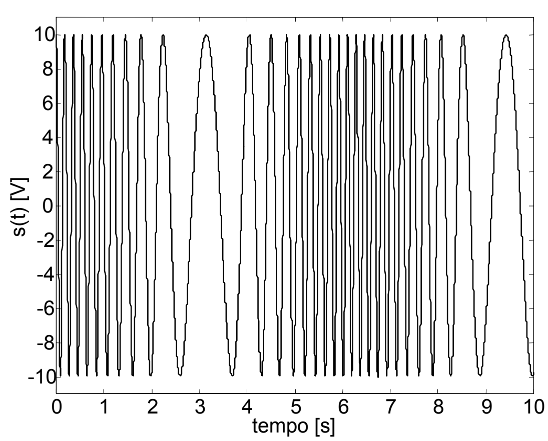

FIGURA 7
SINAL FMFL NO DOMÍNIO DO TEMPO

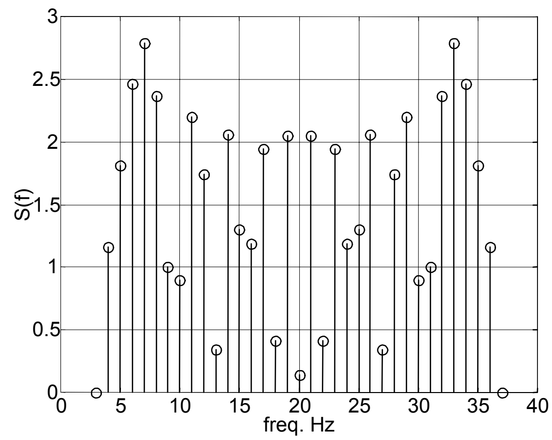

FIGURA 8
SINAL FMFL NO DOMÍNIO DA FREQÜÊNCIA

O módulo FM do software de simulação também é capaz de gerar sinais FMFE (FM Faixa Estreita), e FMFL segundo outros critérios para limitação de componentes espectrais de ordem elevada.

CONCLUSÃO

Aulas expositivas sobre princípios de telecomunicações, apesar de ser um meio muito econômico de ensinar, leva a um aprendizado passivo e de baixa intensidade devido ao fato de se ter uma elevada quantidade de informações que deverão ser visualizadas através de vários gráficos.

Logo, com o advento das ferramentas computacionais de simulação, é possível aumentar a qualidade das aulas expositivas, isto é, além de ilustrar rapidamente os fenômenos ocorrentes nos vários tipos de modulação, consegue-se também atingir aos alunos cujo aprendizado se dá com maior eficiência por métodos visuais e participativos, fazendo com que o método de ensino/aprendizagem torne-se mais eficiente.

A Computer Tool to Analyze the LMS Equalizer

Luciano L. Mendes[1], Francisco J. Fraga[2], Sandro A. Fasolo[3] and Estevan M. Lopes [4]

Abstract *— The purpose of this paper is to explore the concepts involved in adaptive equalization, using a didactical computer tool. The software developed uses the Least Mean Square algorithm to equalize a bit sequence transmitted in base band through a channel defined by the user. The program allows the user to define the size and the nature of the signal used as training sequence, the number of the taps of the equalizer filter and also the channel impulse response. All results are presented in graphics, which allow the user to analyze each step of the equalization process. This program was developed using the Matlab® platform with a Graphic User Interface (GUI).*

Index Terms — Adaptive Equalizer, Didactical Computer Tool, Training Sequence.

INTRODUCTION

This paper presents an educational approach for the study of adaptive equalizers using the LMS (Least Mean Square) algorithm [1]. This approach is realized using a simulation program developed with Matlab® platform, which allows the user to define the parameters of the system, and them analyze the effects of these parameters in the equalization process.

Equalization is fundamental in the reception of digital signals transmitted in channels that presents multiple paths and introduces Intersymbol Interference (ISI) [2][3]. The concepts involved in this process are complexes and must be clearly presented to the students. For this reason it is important to present approaches that allows the students to analyze the system and verify each step of this process. In this paper, the results obtained with the simulator will be presented and analyzed to demonstrate the didactical potential of the developed computer tool. Figure 1 presents the block diagram of a generic adaptive equalizer used in this paper.

SIMULATION STRUCTURE

The simulator was based in the block diagram presented by Figure 2 [1]. In this structure, at the beginning of the communication ($t = t_0$) the transmitter sends a training sequence (a_n) that is known by the receiver. The channel introduces ISI using the impulse response (b_n) provided by the user. The additive white gaussian noise (AWGN) can also be added to the signal and the received signal (r_n) is delivered to the adaptive equalizer. The LMS algorithm uses an error signal provided by the difference between the signal at the output of the equalizer and the training sequence generated at the receiver (reference sequence) to calculate the coefficients. The channel and the equalizer can be modeled as FIR [4] filters that can introduce delays in the signal. Thus, in this case, the training sequence must be properly delayed at the receptor to provide an accurate error signal to feedback the equalizer, allowing the equalizer to compare the reference signal (a_n) with the signal at the equalizer output. The obtained error signal (e_n) is then introduced in the LMS algorithm to update the coefficients that will be used to minimize the ISI introduced by the channel.

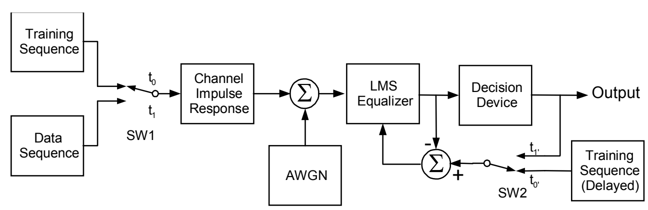

FIGURE 2
SIMULATION BLOCK DIAGRAM.

At the end of the training sequence ($t = t_1$), the equalizer has estimated the channel and the switches 1 and 2 change their positions. The transmission of the data sequence (c_n) begins and, at the receiver, the equalizer assumes that the decision device always estimates the received sequence correctly. The estimated sequence ($\hat{c}_n$) is then used to calculate the error signal that will be used as a feedback to the LMS algorithm. The bit error rate (BER) must be low enough to guarantee that the estimated sequence corresponds to the desired reference sequence. It means that the training

sequence must be long enough to allow the equalizer to estimate the channel correctly and, thus, to reduce the BER.

All sequences involved in this simulation are shown in graphics that allow the user to analyze each step of the equalization process.

SIMULATOR

Following, a group of simulations are presented to demonstrate the use of the simulator.

Simulation with Square Training Sequence

In this simulation, a square training sequence with 256 bits has been used to estimate the channel frequency response. The number of taps of the equalizer has been set to eight and the channel has been modeled for Medium ISI (which means that the channel impulse response is [1 0.2 -0.2 0 0]), with signal to noise ratio (SNR) of 60dB, which almost eliminates the interference of the noise. The data sequence length has been set to 512 bits. Figure 3 shows the transmitted training sequence and this sequence at the channel output. Note that the training sequence is a cyclic square waveform where each period is formed by five bits 1 (+1) and five bits 0 (-1). The amplitude distortion in the signal at the channel output is caused by the ISI.

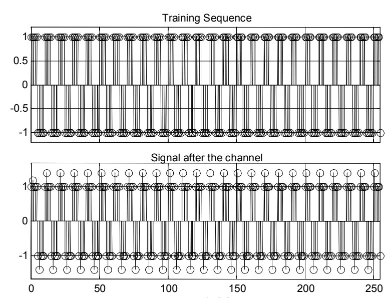

FIGURE 3
SQUARE TRAINING SEQUENCE AND THE OUTPUT OF THE CHANNEL.

The equalizer updates its taps at each received bit from the training sequence. Once defined the delay introduced by the channel, the received training sequence is subtracted from the reference sequence to obtain the error signal, which will be used to feedback the LMS algorithm and update the taps. The update process can be viewed in a dynamic graphic that shows the equalizer impulse response. This graphic is displayed whenever the taps are update. Figure 4 shows the equalizer impulse response at the end of the training sequence, where it is possible to note that the channel has not been correctly estimated, because the equalizer impulse response does not annul the channel impulse response. The distortions introduced by the channel are canceled when (1) is satisfied.

$$c(n) * h(n) = \sum_{k=0}^{N+K-1} h(k) \cdot b(k-n) = \delta(n) \quad (1)$$

Where $\delta(n)$ is the discrete-time impulse function and $h(n)$ is the equalizer impulse response.

Equation (1) shows that the convolution between the channel and equalizer impulse responses must result in a Dirac impulse. Figure 5 shows that the condition presented in (4) has not been reached.

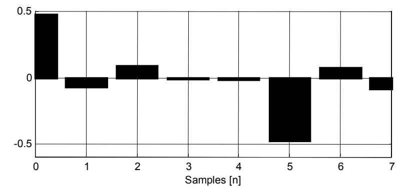

FIGURE 4
EQUALIZER IMPULSE RESPONSE.

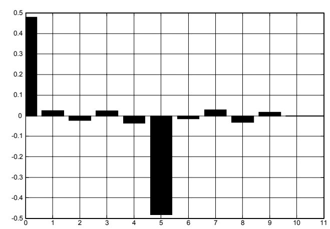

FIGURE 5
CONVOLUTION: EQUALIZER AND CHANNEL IMPULSIVE RESPONSE.

It is also important to analyze the equalization process in the frequency domain. The Fourier Transform of (1) allows one to define the condition to obtain a perfect equalization of the channel, in the frequency domain. Equation (2) shows this condition.

$$\begin{gathered} H(k) \cdot C(k) = 1 \\ \left| H(k) \cdot C(k) \right| = 1 \\ \angle H(k) + \angle C(k) = 0 \end{gathered} \quad (2)$$

Where $H(k)$ is the equalizer frequency response and $C(k)$ is the channel frequency response.

Figure 6 shows the frequency and phase response of the equalizer and channel, where it is possible to observe that the equalizer frequency response only satisfies (2) for some specifics values of frequency (-π, -0.6π, -0.2π, 0.2π, 0.6π e π). This occurs because the square training sequence has discrete spectral components, as shown in Figure 7.

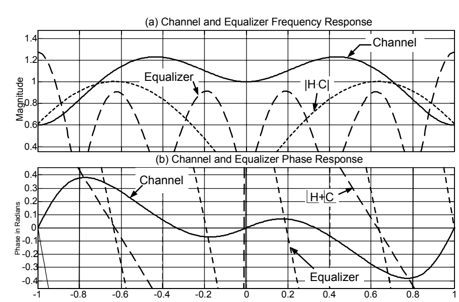

FIGURE 6
CHANNEL AND EQUALIZER FREQUENCY RESPONSE.

If the training sequence does not have spectral components in all frequencies, the equalizer cannot estimate the channel correctly. Because the equalizer corrected the channel in the frequencies where the training sequence has components, the interference in the sequence at the equalizer output has been eliminated.

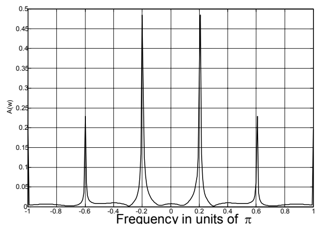

FIGURE 7
SPECTRUM OF THE SQUARE TRAINING SEQUENCE.

Figure 8 shows the error signal during the training sequence, where it is possible to note that the LMS algorithm is able to update the equalizer taps to minimize the error signal.

It can be seen that the equalizer approximates the received sequence to the desired sequence, removing the ISI introduced by the channel, as shown in Figure 9.

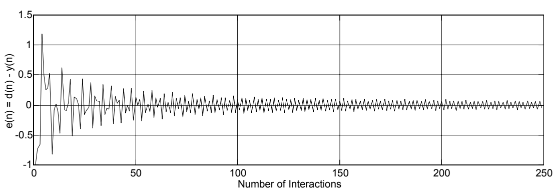

FIGURE 8
ERROR SIGNAL AND MEAN SQUARE ERROR.

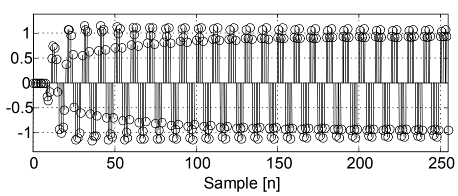

FIGURE 9
EQUALIZED TRAINING SEQUENCE.

At the end of the training sequence, the transmitter begins to send the data sequence and the equalizer begins to use the sequence at the output of the decision device as reference signal. To simulate a data sequence, the program generates a random bit sequence with uniform distribution [5]. The spectrum of a random sequence can be approximate to a constant value for all frequencies of interest, as showed in Figure 10.

To demonstrate the performance of the equalizer, the channel impulse response is randomly changed at the end of the training sequence. This procedure allows the user to analyze if the equalizer proposed is able to update its taps when the data sequence is transmitted. Figure 11 shows the transmitted data sequence and the received data sequence.

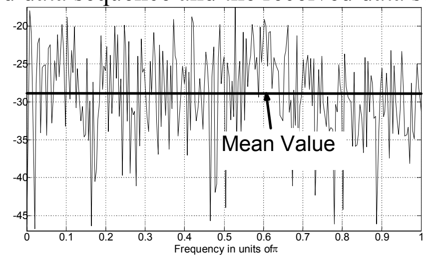

FIGURE 10
SPECTRUM OF THE DATA SEQUENCE.

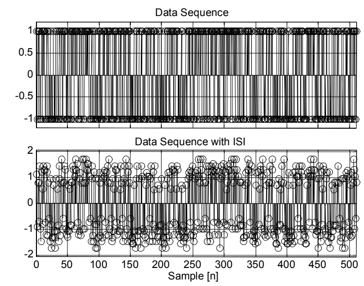

FIGURE 11
DATA SEQUENCE BEFORE AND AFTER THE CHANNEL.

Because the equalizer did not correctly estimate the channel during the training sequence, the BER at the beginning of the data sequence could be high. Thus, the reference sequence, that is the sequence estimated by the decision device, does not correspond to the desired sequence and the equalizer cannot remove the ISI from the received sequence. Figure 12 shows the equalizer and the channel frequency response. The equalizer frequency response does not represent the inverse of the channel frequency response, hence the data sequence delivered to the decision device is distorted by the ISI and the BER could be high. Figure 13 shows the equalized sequence.

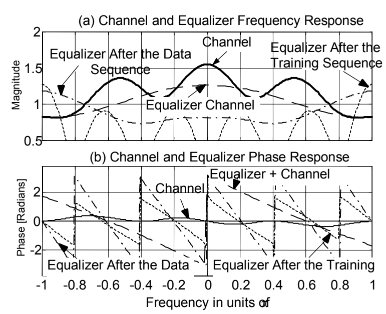

FIGURE 12
CHANNEL AND EQUALIZER FREQUENCY RESPONSE.

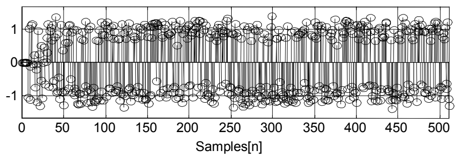

FIGURE 13
EQUALIZED SEQUENCE.

Simulation with Random Training Sequence

As showed in the previous session, it is not possible to use a square waveform to estimate the channel, because square waveforms have discrete spectral components. In this simulation, a random bipolar bit sequence with uniform distribution is used to estimate the channel. Any other parameter of the simulator has not been changed. Figure 14 shows the transmitted and received training sequence.

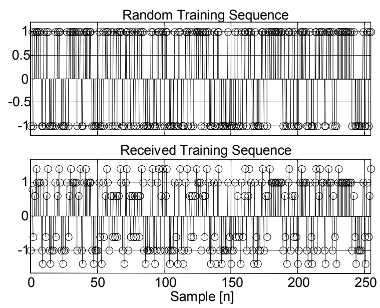

FIGURE 14
TRANSMITTED AND RECEIVED TRAINING SEQUENCE.

As showed in Figure 10, the spectrum of random sequences has components in every frequency. Thus, the equalizer can estimate the channel correctly and update its taps to remove the ISI introduced by the channel. Figure 15 shows the convolution between the channel and equalizer impulse responses, where it is possible to note that the equalizer was able to estimate and compensate the distortions introduced by the channel, once the condition presented in (1) has been satisfied. This conclusion can also be confirmed through Figure 16, where the channel and equalizer frequency responses are presented, as well the product between them.

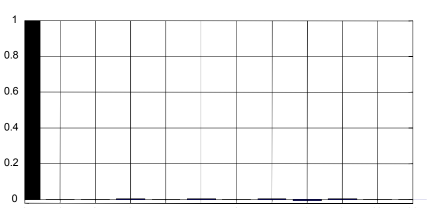

FIGURE 15
CONVOLUTION OF THE CHANNEL AND EQUALIZER IMPULSE RESPONSES

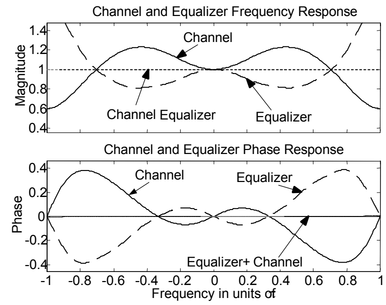

FIGURE 16
CHANNEL AND EQUALIZER FREQUENCY RESPONSE.

The equalized sequence is presented in Figure 17. Note that, after 90 interactions, the equalizer is able to remove the ISI from the signal, which means that after 90 bits of the training sequence, the reference sequence is almost equal to the equalized sequence. Figure 18 shows the equalizer and the channel frequency response after the transmission of the data sequence.

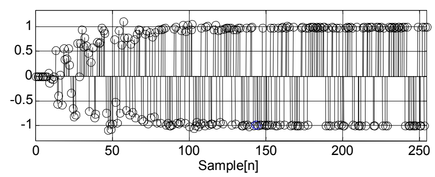

FIGURE 17
EQUALIZED TRAINING SEQUENCE.

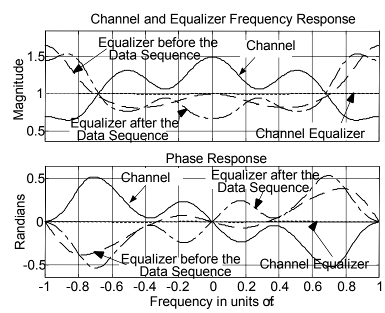

FIGURE 18
CHANNEL AND EQUALIZER FREQUENCY RESPONSE.

The equalizer frequency response is the inverse of the channel frequency response, therefor the statement presented by (2) was satisfied. Figure 19 shows the equalized sequence, where one can note that there are ISI in the beginning of the data sequence, because of the random variation in the channel impulse response, but the equalizer successfully update its taps to remove any interference introduced by the channel.

Although the random training sequence has characteristics that allow the equalizer to estimate correctly the channel, its use is not practical because the receiver can not generate the same random sequence generated by the transmitter. Thus it is not possible to obtain a reference sequence in the receiver to calculate the error signal.

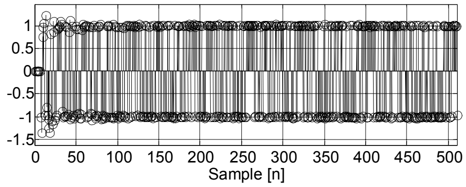

FIGURE 19
EQUALIZED DATA SEQUENCE.

Simulation with Pseudo Random Training Sequence.

The pseudo random sequences or pseudo noise (PN) sequences [2][3] present a solution for the training process because it behaves as a random sequence during each cycle of *N* samples. Once known the generator polynomial and the initial conditions, the receiver is able to generate the same sequence used by the transmitter. Thus, it is possible to use a PN sequence as a training sequence to estimate the channel frequency response. In this simulation, a PN sequence is used to train the equalizer with the same configuration presented in the previous sessions. Figure 20 shows the transmitted and received training sequence and Figure 21 shows its spectrum. It is possible to note that PN sequence does not have a uniform spectrum as a random sequence, but it presents a spectrum with energy well distributed in the bandwidth of interest. This allows the equalizer to estimate the channel and avoid high bit error rates during the transmission of the data sequence. Figure 22 shows the equalizer and channel frequency responses, as well, the product between them.

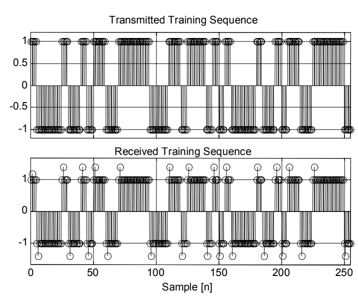

FIGURE 20
TRANSMITTED AND RECEIVED TRAINING SEQUENCE

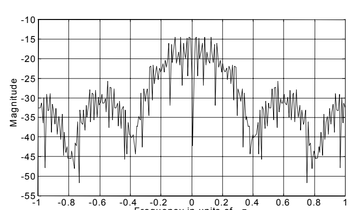

FIGURE 21
SPECTRUM OF THE TRANSMITTED TRAINING SEQUENCE.

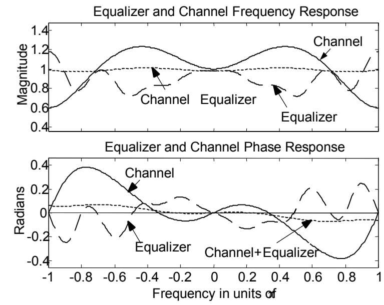

FIGURE 22
CHANNEL AND EQUALIZER FREQUENCY RESPONSE AFTER THE TRAINING SEQUENCE.

The resulting frequency response is not perfectly flat, but it is flat enough to avoid high BER during the transmission of the data sequence. Figure 23 shows that the equalizer has been able to correctly estimate the variation of the channel impulse response during the transmission of the data sequence.

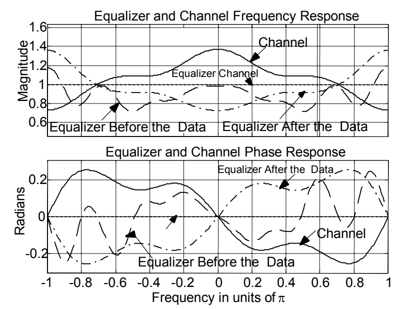

FIGURE 23
CHANNEL AND EQUALIZER FREQUENCY RESPONSE.

CONCLUSIONS

This paper has presented a didactic simulator to analyze a LMS adaptive equalizer, with some commented results obtained in three simulations. The first simulation showed that square waveform cannot be used to estimate the equalizer because cyclic waveforms have discrete spectral components, which does not allow the equalizer to correctly estimate the channel. The second simulation has presented the results obtained with a random training sequence. Although the obtained results demonstrate that a random sequence allows the equalizer to estimate the channel, this procedure cannot be used in practice because the receiver cannot generate the same random sequence used by the transmitter. Finally, the third simulation has presented a practical solution to train the equalizer properly. The PN sequences have spectra with energy distributed in the bandwidth of interest which allows the equalizer to estimate the channel. Although the energy distribution of a PN sequence spectrum is not uniform as in the random sequence spectrum, the PN sequence allows the equalizer to remove the ISI from the transmitted sequences, which can guarantee a low BER during the transmission of the data sequence.

A SIMPLE LPC AND RELP VOCODERS SIMULATION PROGRAM DEVELOPED ON THE MATLAB® PLATFORM

Fábio A. R. Nascimento[1], Alan M. Marotta[2] and Francisco J. Fraga[3]

Abstract *— The widespread use of mobile telephones has reinforced the importance of coding and transmitting speech at low bit rates. As a natural consequence, the interest of researchers and postgraduate students in the speech coding area has increased significantly over the last years. A special attention has been focused on the topic of parametric LPC-based (LPC: Linear Predictive Coding) Voice Encoders (VOCODERS). This class of Vocoders offers the most promising bandwidth-quality trade-off. This paper presents a simulation program wrote on the Matlab® platform which allows postgraduate students understanding the basic principles of the LPC and RELP (Residual Excited Linear Prediction) Vocoders. The resulting speech signal can be heard and also visually compared with the original signal. By means of this tool, the student can also compare the trade-off between the quality of the synthesized speech and the bit-rate reduction, for both the LPC and RELP Vocoders.*

Index terms — LPC Vocoder, RELP Vocoder, Speaking Machine, Vocoders simulation.

INTRODUCTION

There are several *LPC-based* speech coding techniques with low bit rate already standardized and commercially implemented. An example is the ADPCM system that requires one half of the PCM bit rate, with the same performance. In the case of speech (or voice) transmission, there are even bolder techniques, reducing up to 8 times the PCM rate, paying the price of a slight loss of quality. To do so, a speech production model becomes necessary, where some characteristic properties of this kind of signals are applied. The systems using this approach are called Vocoders [1], a term derived from *voice encoders*.

The strategy used for the construction of this kind of circuits is based on the transmission of the voice parameters, instead of transmitting the voice signal itself, as following described. Studies on the modeling of the human speech production system are lead, officially, since 1780, with the experiments of Von Kempelem and its speaking machine [1]. Nowadays this study has already gone reasonably deep and it is possible to get a very good model of the human speech production system by a discrete-time system. Thus, it is possible to implement at the transmitter a circuit capable to analyze the input speech signal and to provide at the output the codified parameters of this signal. If we implement a speech synthesis sub-system at the receiver with the received parameters, then we have got a system that is able to transmit only the parameters of the original speech signal, but with good intelligibility at the receiver output. This leads to an enormous decrease in the transmission bit rate.

Nevertheless, in order to obtain better speech quality, we have to look for more elaborated Vocoders, where more advanced techniques are used, such as CELP (Code Excited Linear Prediction) and VSELP (Vector Sum Excited Linear Prediction) [2]. As an example, a VSELP Vocoder, which is the TIA (Telecommunications Industry Association) coding scheme for cellular telephony in the United States, is able to codify speech at 8 Kbps with an acceptable level of quality. Such low bit rate signifies almost a 10:1 bandwidth reduction factor, if compared to standard PCM (64 Kbps).

Although commercial Vocoders like VSELP present a high level of complexity, all of them are based on LPC techniques, which have not so complex theoretical principles. With aim of teaching the LPC techniques in an efficient way, it is important to develop some computer-based educational methods to make easier the comprehension of their theoretical concepts. This is the goal of the program we have developed and described here.

THE LPC VOCODER

The LPC VOCODER is a discrete-time speech production system, as illustrated in figures 1 and 2.

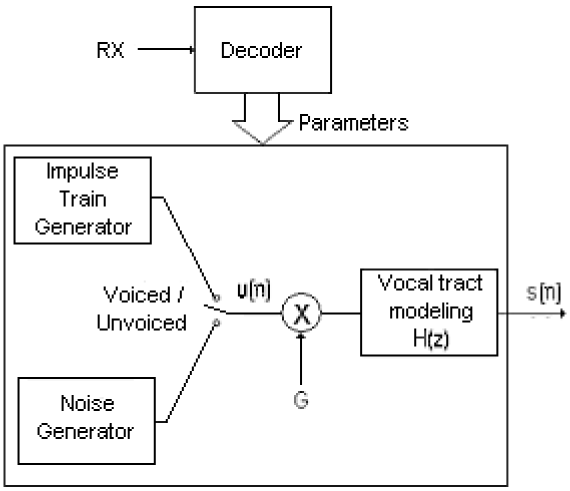

FIGURE. 2
LPC Vocoder Receiver

One can find strange the use of an impulse train generator and a noise generator at the receiver in order to reproduce the speech. But an analysis of the speech signal leads us to agree with the idea that the voiced sounds have a fundamental frequency, known as pitch frequency, and the unvoiced sounds are very similar to a noisy sound. Thus, we can admit that the excitation signal can be reasonably substituted by an impulse train for voiced sounds and by a random noise signal for unvoiced sounds [3]. In figure 3 we can see an illustration containing the speech signal generated from the pronunciation of the word "vocoder".

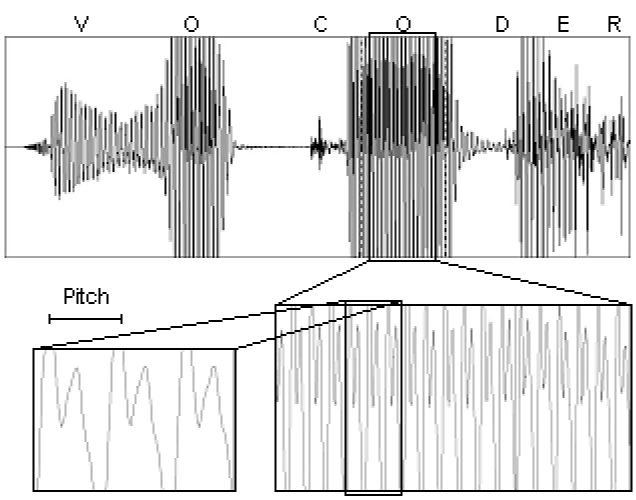

FIGURE. 3
SPEECH SIGNAL IN THE TIME DOMAIN

Another relevant point is the implementation of a vocal tract modeling filter, with transfer function H(z). Using linear prediction concepts applied to the speech signal, we are able to determine the parameters that describe such a filter. The parameters that are essential to an intelligible speech reproduction at the receiver are, as we can foresee by analyzing the figures 1, 2 and 3, the impulse train frequency, which is determined from the *pitch*; the vocal tract *modeling filter coefficients* and the *gain* of the excitation signal.

The mathematical modeling representing the output speech signal of the decoder circuit is shown below [4]:

$$s(n) = \sum_{k=1}^{p} a_k s(n-k) + Gu(n) \tag{1}$$

The expression that represents the speech modeling filter transfer function is [4]

$$H(z) = \frac{G}{1 - \sum_{k=1}^{p} a_k z^{-k}}, \tag{2}$$

where a_k are filter coefficients corresponding to the transfer function poles. As we notice, this function just contains poles; although it is able to perform a good approximation of the vocal tract, with small damage to the nasal and fricative sounds, which would require a function containing also zeros, if we desire a more accurate speech production model.

CALCULATING THE FILTER COEFFICIENTS

A proper approach to the calculus of the *filter coefficients* is related to minimum mean-square error. Following this idea, the expression of the prediction mean-square error is

$$J = E\left[e^2(n)\right]$$

$$J = E\left[\left(s(n) - \sum_{i=1}^{p} a_i s(n-i)\right)^2\right], \tag{3}$$

where $s(n)$ is the speech signal (windowed in frames with a typical duration of 20 to 30 ms) and a_i are *filter coefficients*.

Expanding the expression above, we have

$$J = E\left[s^2(n)\right] - 2\sum_{i=1}^{p} a_i E\left[s(n)s(n-i)\right] + \sum_{k=1}^{p}\sum_{i=1}^{p} a_k a_i E\left[s(n-k)s(n-i)\right] \tag{4}$$

Assuming that $s(n)$ is a sample function of a stationary process, we have

$$J = R(0) - 2\sum_{i=1}^{p} a_i R(i) + \sum_{k=1}^{p}\sum_{i=1}^{p} a_k a_i R(i-k), \qquad (5)$$

where $R(i)$ are samples of the auto-correlation function of the speech signal, which can be obtained by the auto-correlation of the speech signal in each frame [4]:

$$R(k) = \sum_{n=1}^{N} s(n)s(n+k) \qquad 1 \le k \le p, \qquad (6)$$

where p is the prediction filter order, normally chosen between 8 and 12. The idea is to minimize the mean-square error, and this approach will lead us to obtain the proper coefficients. To do so, we derive J in relation to the coefficient of order i and make the resulting expression equal to zero. Thus, we obtain the following expression [5]:

$$\sum_{k=1}^{p} a_k R(i-k) = R(i) \qquad i = 1,2,\ldots,p \qquad (7)$$

In the matrix form we have

$$\mathbf{a} \cdot \mathbf{R} = \mathbf{r} \qquad (8)$$

where

$$\mathbf{a} = [a_1, a_2, \ldots, a_p]^T$$

$$\mathbf{R} = \begin{bmatrix} R[0] & R[1] & \ldots & \ldots & R[p-1] \\ R[1] & R[0] & \ldots & \ldots & R[p-2] \\ : & : & \ldots & \ldots & : \\ : & : & \ldots & \ldots & : \\ R[p-1] & R[p-2] & \ldots & \ldots & R[0] \end{bmatrix}$$

and

$$\mathbf{r} = \left[R[1], R[2], \ldots, R[p]\right]^T$$

The set of equations (7) or (8) are called the Wiener-Hopf equations for linear prediction and their solution lead us to

$$\mathbf{a} = \mathbf{R}^{-1} \cdot \mathbf{r} \qquad (9)$$

$$J_{\min} = R(0) - \mathbf{r}^{\mathbf{T}} \cdot \mathbf{R}^{-1} \cdot \mathbf{r} \qquad (10)$$

CALCULATING THE PITCH

The algorithm used to detect the pitch requires the definition of new parameters: the auto-correlation of $\mathbf{a}$ (*filter coefficients auto-correlation function*):

$$R_a(i) = \sum_{k=1}^{p} a_k a_{k+i} \qquad 1 \le i \le p \qquad (11)$$

where a_{k+i} is zero if $k + i > p$

The convolution of $R_a(i)$ with $R(l)$:

$$R_e(l) = \sum_{i=1}^{p} R_a(i) R(l-i) \qquad (12)$$

where $R(l)$ can be calculated by equation (6) with $0 \le l \le N-1$. Normalizing $R_e(l)$, we have

$$R_{eN}(l) = R_e(l) / R_e(0) \qquad (13)$$

If the maximum value of $R_{eN}(l)$ is equal or superior to a threshold γ (the most used value for γ = 0.25), then we may consider we have a voiced frame. On the contrary, if $R_{eN}(l)$ is inferior to γ, then we may consider we have an unvoiced frame and, consequently, there is no pitch. If the frame is considered as voiced, the value of the pitch period is set by the position (sample index) where the maximum value of $R_{eN}(l)$ occurs.

CALCULATING THE GAIN

The gain of the signal is easily deducted from the following concept:

$$Gu(n) = e(n) = s(n) - \sum_{k=1}^{p} a_k s(n-k). \qquad (14)$$

THE RELP VOCODER

Unlike the LPC Vocoder, the RELP (Residual Excited Linear Prediction) Vocoder [3], instead of considering the excitation signal at the decoder as an impulse train or a random noise, it codifies and transmits the prediction error (or *residual*) signal *e(n)*, which is the proper excitation signal. This procedure requires a higher bit rate, but, on the other hand, it does a better job by capturing true characteristics of the original signal through residual signal. It is obvious that it does not make any sense to transmit a signal of such complexity like the error signal as it is. So, we use the artifice of *decimating* it (after low pass filtering) by some decimate factor of at least four (reducing four times the number of samples), before transmitting it. This requires that the decoder perform the inverse process, over-sampling the error signal received, in order to recover the original amount of samples. Then, the decimated samples at the encoder are interpreted as zero at the decoder. Even with this loss introduced for the decimate process, the subjective result is considered much better than the one obtained with the LPC Vocoder.

Thus, the parameters to be transmitted are the *filter coefficients* and the *decimated error signal* or *decimated prediction residue.*

MATLAB IMPLEMENTATION

Bearing in mind that one of our goals is to evaluate the Vocoders transmission rate, comparing it to other systems, a good approach is to use the PCM standard system as our reference. So we may consider speech signals sampled with the same sampling rate and the same number of quantization levels that those in the PCM Standard system, where the sampling frequency f_s = 8 kHz and the quantization levels are 256 (8 bits), leading us to a 64 Kbps bit rate.

In order to derive the filter coefficients we assumed that the speech signal $s(n)$ was a stationary signal. This is not true, due to modifications of the vocal tract characteristics along the time, which allow us to pronounce different phonemes. Fortunately, these modifications have a small variation rate, permitting us to consider that the voice signal is stationary in a short time interval T_q (20 to 30 ms) [1]. Considering the above concept, we notice that the speech signal must be recorded and sub-divided in N_q frames, where N_q is equal to the duration time T_s of the complete speech signal divided by the frame duration time T_q

$$N_q = \frac{T_s}{T_q} . \tag{15}$$

The number of samples for each frame is equal to its duration time T_q multiplied by the sample frequency f_s

$$N = T_q f_s . \tag{16}$$

The parameters are extracted and transmitted for each frame. The *filter coefficients* for each frame are derived from equation (9), after calculating the auto-correlation of the speech signal in each frame.

It is important to notice that the higher is the prediction filter order, the more precise is the prediction signal and, consequently, smaller the error. However, the error does not decrease significantly for a filter order above 12. Values higher than this order set more parameters to be transmitted, but with almost any improvement of the subjective performance. Therefore, the developer must find the better relation between subjective quality and the required transmission rate, when setting the filter order. The standardized LPC-10 Vocoder, as its name suggests, uses p = 10 prediction coefficients.

Then, let us consider p coefficients for each frame, being each of them satisfactorily encoded with 3 decimal points of precision, what sets 10 bits for encoding and transmitting each coefficient. The necessary transmission rate for the parameter *filter coefficients* is calculated by multiplying the amount of required bits for each coefficient by the number of coefficients in each frame and by the number of frames contained in one second:

$$R_a = 10 \frac{p}{T_q} \tag{17}$$

The parameter *filter coefficients* is necessary for both LPC and RELP Vocoders.

We will deal now with implementation issues related with the *pitch* and *gain* parameters, which are necessary only for the LPC Vocoder. Following, we will consider the *prediction error* parameter, which is required only for the RELP Vocoder.

It is possible to prove [4] that we can directly obtain the parameter *gain* using the equation

$$G = \sqrt{R(0) + \sum_{k=1}^{p} a_k R(k)} . \tag{18}$$

Typically 5 bits are needed for binary representation of the parameter *gain* for one frame [4]. Its transmission rate is calculated by multiplying the necessary amount of bits for representing the parameter for one frame by the number of frames in one second:

$$R_g = \frac{5}{T_q} . \tag{19}$$

The extraction of the parameter *pitch* is done directly through the equations (11), (12) and (13), associated with a routine that looks for the sample index of the peak of the normalized cross-correlation signal:

$$T_o = \max_l \left[R_{eN}(l) \right]. \tag{20}$$

Usually we consider that 6 bits are enough for the binary representation of the parameter *pitch* (T_0) for each frame [4]. Its transmission rate is calculated by multiplying the required amount of bits to represent it for one frame by the number of frames in one second:

$$R_p = \frac{6}{T_q}. \quad (21)$$

In case of Vocoder RELP, as mentioned above, the *filter coefficients* are obtained exactly the same way as in the LPC case. The extraction of the parameter *decimated prediction error* is made by applying the definition

$$e(n) = s(n) - \hat{s}(n), \quad (22)$$

where $s(n)$ is the original speech signal and $\hat{s}(n)$ is the predicted signal, obtained from a digital filter with unitary gain and denominator coefficients a_k.

The decimation is done by low pass filtering the error signal and by considering one sample among each group of d samples, setting as zero the other ones, where d is the decimation factor. Let us represent the decimation function and its decimation factor d by Dec_d. So, the *decimated prediction error* parameter is

$$e_d(n) = Dec_d\left[e(n)\right]. \quad (23)$$

The parameter *decimated prediction residue* requires a lot of bits, because every d^{th} sample of the prediction error signal $e(n)$ must be encoded and transmitted. A similar coding concept occurs in the case of the DPCM system. It is known that the DPCM system represents a reduction of two bits per sample in relation to the PCM system [5]. Thus, 6 bits are enough for coding this parameter properly.

The bit rate due to this parameter is evaluated by multiplying the number of bits needed for representing one sample by the number of samples in one second, divided by the decimation factor

$$R_e = \frac{6 f_s}{d}. \quad (24)$$

The LPC synthesis is obtained through the implementation of a digital filter, obtained with the received and decoded a_k, G and T_0 parameters. The input signal of the filter defined right above may be of two types: an impulse train, with period defined by the *pitch* parameter T_0, for voiced sounds; or by a random noise signal for unvoiced sounds. The total bit rate for the LPC-10 vocoder (f_s = 8 KHz, p =10 and T_q = 25 ms) will be then equal to

$$R_{LPC} = R_a + R_g + R_p$$
$$R_{LPC} = 4{,}44 \text{ Kbps}$$

The RELP synthesis is obtained through the implementation of a digital filter, with the received and decoded a_k parameters and unity gain. The input signal for the filter mentioned right above is the received, decoded and over-sampled parameter $e_d(n)$. The total bit rate for the RELP vocoder (f_s = 8 kHz, p =10, d = 4, T_q = 25 ms) is

$$R_{RELP} = R_a + R_e$$
$$R_{RELP} = 16 \text{ Kbps}$$

CONCLUSIONS

The Matlab implementation of these two Vocoders is relatively easy due to its facility of implementing routines that work with matrices and vectors, beside its variety of built-in functions that can be used. The bit rate tests and also the final subjective results show to anyone who uses the software that there is a quality enhance of the decoded signal obtained by the RELP Vocoder, but with the trade-off of a significant increase of the bit rate if compared with the LPC Vocoder.

Finally, we want to remark that our experience with the master students that helped in the development of this software and with the others that used it for learning the LPC coding techniques demonstrated to be very profitable for our educational purposes.

AN EDUCATIONAL APPROACH FOR THE ANALYSIS OF PMD AND SOME LINEAR EFFECTS IN OPTICAL COMMUNICATION SYSTEMS

Josias de Lima Bernardes[1], Breno Luiz Lima Santos[2], Maurício Silveira[3], José A. Justino Ribeiro[4]

Abstract *— With the high transmission rate that the optical communication systems require nowadays, the reduction of Polarization Mode Dispersion – PMD effect is strongly considerate. The main purpose of this paper is to show how to simulate the influence of PMD effect and other linear effects. The great Companies involved in the sector of telecommunications have tested the efficiency of optical devices, using sophisticated surrounding computational tools of simulation before these can be implemented. The PMD studies, in their majority, have been idealized in simulation laboratories, which brings a considerable economy allowing them to optimize each enlace of communication. It can be used in the sizing of many parts of the system, over all, in those for long distances and in the global mapping of a determined network system, through an efficient computational surrounding of simulation - the Virtual Photonic Incorporated - VPI, considered the best and more advanced software in simulation of optical transmission systems in the world.*

Index Terms *— Attenuation, Dispersion Compensation, Polarization Mode Dispersion, and DWDM systems.*

INTRODUCTION

The attenuation, was one of the first properties of optical fibers intensely to be studied. Actually, just the optical fiber appearance with losses inferior to 20 dB/km invokes a strong use for the information transport, having the attenuation been the main limiter to the increase of the capacity of the systems during many years. However, with the development of the technology of the production of optical fibers added to the sprouting of the optical amplifiers a great technological advance it was obtained.

Though with the advent of systems with raised transmission rate, demanding the use of very short pulses, making with that the widening of the pulses provoked for the dispersion becomes the main limiting factor to increase the capacity of the systems. Several techniques have been used, with the objective to control this dispersion.

The continuous exertion in increasing the transmission rate and the length of the link imposes appearance of new restrictive factors, known as non-linear effects. In addition, in high rates the birefringence of optical fibers brings some due to fact of the light does not keep its polarization when spreading through the fiber.

ATTENUATION

The attenuation quantifies the loss of energy of the optical signal during the propagation. If P_{in}, is the optical input power applied at the input of a fiber with L_t length, in the output we have P_{out}, satisfying:

$$P_{out} = P_{in} \cdot \exp(-\alpha L_t) \tag{1}$$

where α is the attenuation constant. The equation (1) indicates that the optical power decays with an exponential law. Ordinarily, the losses of the fiber are quantified in *dB/km*.

The losses of the fiber are dependents of several factors, known as absorption, diffusion and radiation. In optical fibers, the electrical field recovers all regions between the nucleous and the covering, being the losses an average of those presented in each layers of the fiber.

It is verified that the losses have strong dependence of the wavelength in optical communication systems. The silica optical fibers present several windows of transparency comprehended between the wavelengths of *600 - 2000 nm*.

The losses for absorption can have origin in the following phenomena: the intrinsic absorption, the extrinsical absorption and the absorption for atomic defects. The intrinsic absorption is a characteristic of the used material, which in this case is the silica. This absorption is less than *0,03 dB/Km* for wavelengths between *1300 – 1600 nm*. The extrinsical absorption must to have the presence of impurities in the fiber. Owing the sophisticated methods used in the manufacture of fibers currently, we can see that the extrinsical absorption is dominated by the presence of a very small amount ions of $(OH)^-$ and they are strong responsible for the fiber attenuation curve form as a function of the wavelength.

The absorption for atomic defects, as itself name indicates, must includes irregularities in the fiber atomic

[1] Josias de Lima Bernardes, INATEL, National Institute of Telecom, Av. João de Camargo, 510, ZC 37540-000 - Santa Rita do Sapucaí – MG, Brazil, josiasl@inatel.br
[2] Breno Luiz Lima Santos, INATEL,brenol@inatel.br
[3] Maurício Silveira, INATEL, msilveira@inatel.br
[4] José Antônio Justino Ribeiro, INATEL, justino@inatel.br

structure. In normal conditions, the absorption due to these irregularities is worthless, comparatively to the total absorption. However, it can be significant if the fiber will be exposed in the strong radiation that provoked some the alterations in its atomic structure. The losses for diffusion must to have the microscopic variations of the material density, and result in its amorphous nature.

In microscopical variations in the density of the material, some microscopic fluctuations of the refractive index are created, that gives an origin to the diffusion of Rayleigh. This diffusion is a basic limit for all losses of the fiber, transferring part of the contained optical energy in guided modes of propagation to ways not guided. For the current processes of manufacture, the extrinsical absorption due to ions of $(OH)^-$ and the diffusion of Rayleigh are the dominant phenomena for the attenuation of optical fibers.

When microcurvatures are present or curvatures with much closed angles, the losses for radiation appear through the long of the passage fiber. These curvatures can occur at the macrocospic level, due to the passage that the fiber covers, or at the level microscope (microcurvatures), proceeding from the introduction at the fiber in the handle, twist or stress. These losses generally are quantified jointly with those due to the use of connectors and amendment in the fiber, having assigned losses in the handle. These have strong dependence on the installation and the cabling configuration of the optical communication system.

The effect of the attenuation in the fiber can be simulated, leading in consideration the input and output powers. One notices that when the input power is increased the output power also increases, which implies that the gain curve has a notable fall. The attenuation can be solved with the use of an optical doped amplifier (EDFA), as it is shown in Fig. 1.

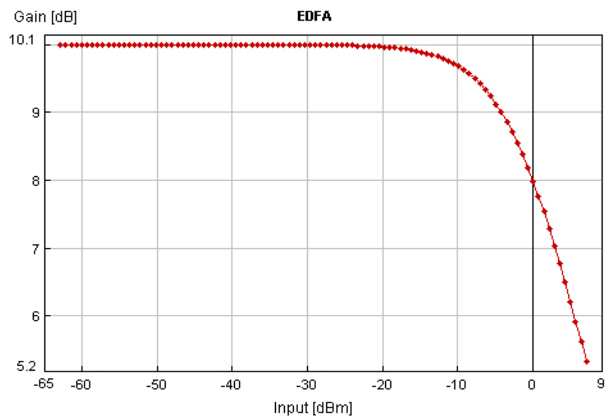

Fig.1 Attenuation Graphic

In the Fig. 2, we can see the used diagram block-type in VPI's simulation.

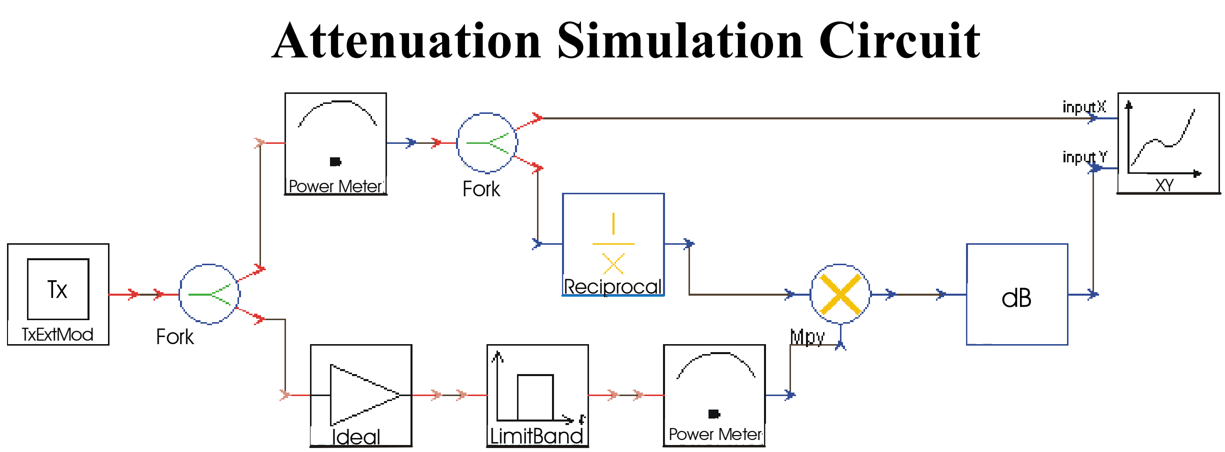

Fig.2 Attenuation Simulation Circuit

Dispersion

The development of the amount of data and the appearance of new services of telecommunication have forced continuously the increase of the capacity of transmission in all link of optical fibers. The attenuation and the dispersion of the fiber are the main obstacles in this process. The appearance of the EDFA already eliminated the barrier imposed for the attenuation.

However for the dispersion, specific strategies of compensation must be adopted in the link it order to be able to operate in rates greater than *10 Gbit/s*.

The dispersion is a transmission characteristic that represents the widening of the transmitted pulses. This widening determines the bandwidth of the optical fiber, specified in *(MHz.km)* and is related with the capacity of transmission of information in the fibers. The dispersion effects are divided in modal dispersion and chromatic dispersion.

In Fig.4 and Fig.5, by using the VPI platform, it can be proven that the pulse through the long of the fiber suffers a temporary widening, as already cited above.

This effect was simulated taking into consideration a length of *100 (Km)* of multimode fiber and with attenuation factor equal the zero *(dB/Km)*.

In the Fig. 3, we can see the used diagram block-type in VPI simulation.

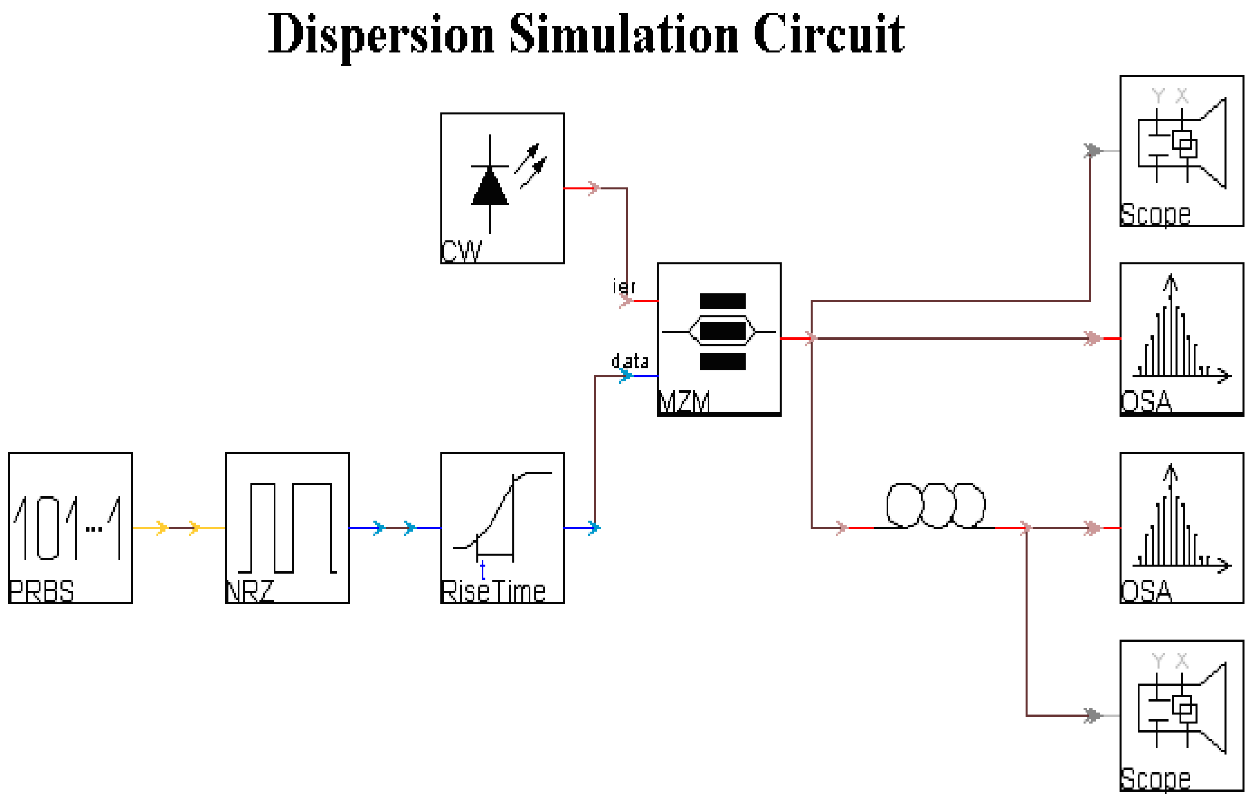

Fig.3 Dispersion Simulation Circuit

Modal Dispersion

This type of dispersion exists in multimode fibers step and gradual, being provoked for some possible ways of propagation that the light could have in the nucleous. In a step fiber, all modes travel with the same speed, therefore the refractive index is constant in the nucleous. Soon, the modes of high order, that in general cover a longer way, will delay more time to leave the fiber that low order modes. In this type, the difference between the arrival times is given by $\tau = \Delta \cdot t_1$, where t_1 is the time of propagation of the low order mode and $\mathbf{\Delta}$ is the percentual difference of refractive index between the nucleous and the covering given by $\mathbf{\Delta} = (n_1 - n_2)/n_2$.

The modal dispersion does not exist in fibers monomode therefore only one mode will be guided through the fiber.

Chromatic Dispersion

This appears due to the fact of the light to be composed for radiation of diverse wavelengths, and during the transmission, all differences in the propagation speed determine the diversity of beams of the light.

This type of dispersion depends on the wavelength and is divided in two types: material dispersion and dispersion of waveguide.

Material Dispersion

As the refractive index depends on the wavelength and as existing luminous sources are not ideal, or either, they possess a certain finite spectral width $\Delta\lambda$, we have that each wavelength is related with a different value of the refractive index in a determined point. Soon each wavelength travels in the nucleous with different speed, provoking a time difference of passage and causing the dispersion of the luminous pulse.

Dispersion of Waveguide

This type of dispersion is provoked by variations in the dimensions of the nucleous and variations in the profile of the refractive index through the long of the optical fiber and depends on the wavelength. This dispersion is observed in monomodes fibers that have material dispersion reduced.

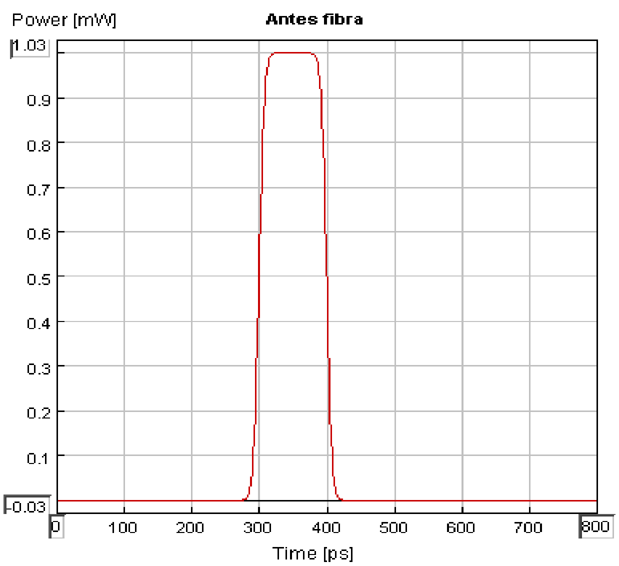

Fig.4 Signal in the input fiber

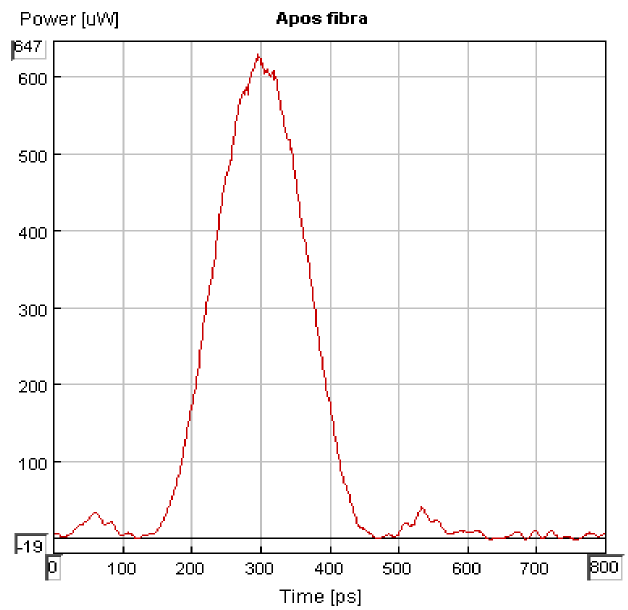

Fig.5 Signal in the output fiber

POLARIZATION MODE DISPERSION – PMD

The PMD is a fundamental effect presents in all fibers (*Dispersion Shifted - DS*) and systems operating in the region next to zero-dispersion, where the contribution of the first orders *(group delay)* increases. Due to the birefringence of the fiber, it is possible to get many different modes of propagation.

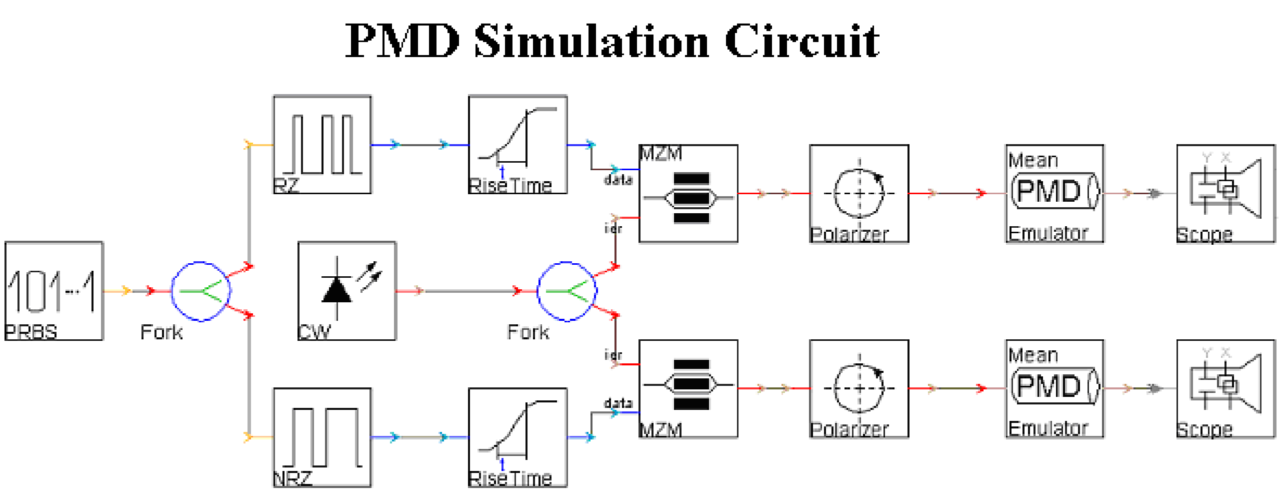

Fig.6 PMD Simulation Circuit

The *interaction* between these modes provokes the delay of a distinguished group, making with that the signal propagates in different speeds, exhausting itself. The main effect caused in the optical system is the intersimbolic interference.

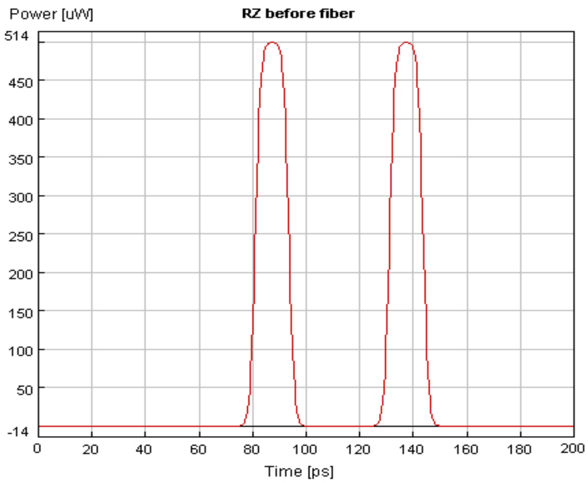

Fig.7 RZ before the fiber

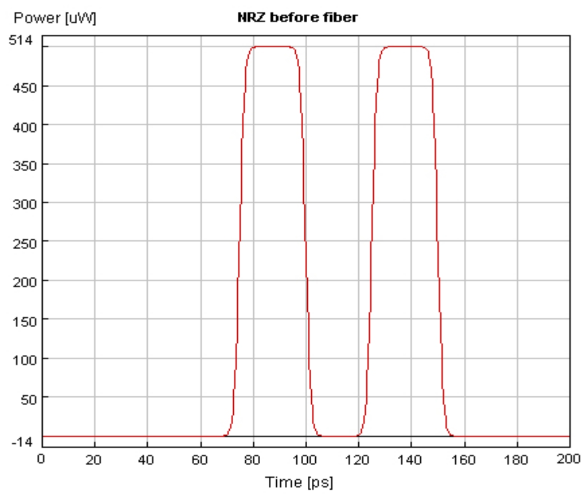

Fig.8 NRZ before the fiber

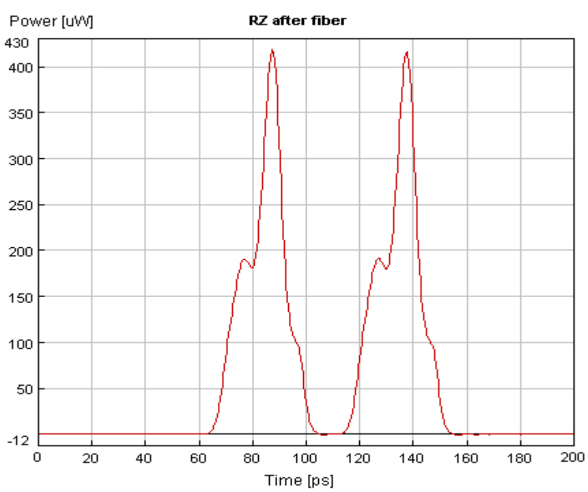

Fig.9 RZ after the fiber

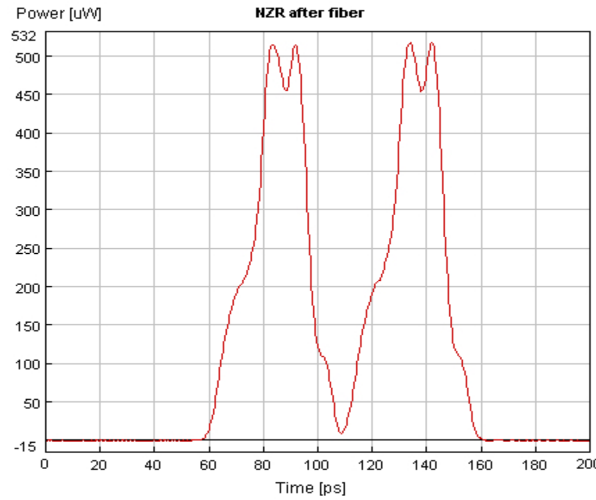

Fig.10 NRZ after the fiber

CONCLUSION

In this paper, the analysis of linear and the PMD effects in optical fibers can degrade the signal in optical communication system with high transmission rate. Practical simulations using the efficient numerical platform VPI had allowed to visualize the consequences in all transmissions that use the multiplexing with high-density wavelength (DWDM).

Despite of some evidences that make progress with the simulations, this work detached the efficiency of the use of RZ codification in comparison with the NRZ one, related with the PMD effect, using an EDFA to compensate the attenuation and, widening transmitted pulses provoked by the dispersion.

Improvement of performance in cellular communications systems with the use of adaptive arrays

Vagner Vilela de Faria, Danilo Lara Carielo, Juliano Silva Brandão,
José Antônio Justino Ribeiro, Maurício Silveira

Abstract – Smart antennas is a system consisting of antenna array and adaptive processor that can adjust the main lobe of the radiation diagram. The direction of main beam maximum and the beam width are determined by a pilot signal. The system can reject or attenuate interference signals or noises occurring outside the main lobe. This performance is obtained if the output signals of the elements of antenna array are properly combined to reduce the interference according to specified directions.

Keywords – Adaptive arrays, BER, Switched beam, Interference.

I. Introduction

The object of this paper is to present a part of the technology of smart antennas, used to improve the performance of radio communication systems. The assignment of smart antennas is an array of radiating elements, each one excited by a signal with amplitude and phase adjusted to control the format and the direction of main lobe and nulls of the radiation diagram.[1] With the control of the radiation diagram, smart antennas can reduce the effect of the interferences, to increase the amplitude of the desired signals and to guarantee increase in the reliability of some types of radio link. The improvement in quality is obtained by increasing the signal-to-noise ratio, reducing the adjacent channel interference or the interference of same channel used in different cells of a cellular telephony system, named as co-channels interference. It allows the reduction or even the suppression of interferences originated by multipath propagation. By reaching the control of the main beam maximum it can be used only the necessary power in each cell, leading to an energy save in the general equipment consumption .[2]-[4]

II. Smart Antennas Features

In radio communications systems, there are factors related to the transmission channel that produce degradation of the signal. There are alterations in the amplitude and form of the modulation signal, mainly in modern systems transmitting digital signals. A purpose of smart antennas systems is to supply resources to correct some bad effects in propagation. Among these difficulties, the co-channel and multipath interferences are critical problems that can damage the reliability of the radio link. [7][8] The co-channel interference appears in systems that use cellular architecture, because the same channels are simultaneously used in different cells and with the lesser possible distance to guarantee the quality of communication. Therefore, the base station that receives a signal from a mobile equipment in its cell also receives undesirable signals from other cells that use the same carrier frequency. There is a commitment between the degradation imposed for the co-channel interference and the reuse of frequencies.[7]

The management of the co-channel interference is an important factor in magnifying systems capacity. To mitigate this effect, smart antennas systems both appoint the radiation diagram maximum to the desired users and, in many situations, also guide null points of the radiation to undesirable users. The smart antennas systems often are presented in the form of structures with switched beam or adaptive arrays[1]. Systems of antennas with switched beam form multiples fixed main lobes, with adequate sensitivity to specified directions. The second type allows a dynamic control of the diagram format to fulfill the requirements of link. The performance of this model will be object of this presentation.

III. Adaptive Array

The advantages of a system of adaptive arrays are increase the gain of the desired signal, the orientation capacity of nulls in the undesirable signals directions, the reduction of the multipath effect and greater exploitation of the electromagnetic spectrum.[1][2] The fulfillment of all these factors guarantees a much better system performance. To radiate the resulting signal in the desirable user direction, it is necessary to adjust the amplitudes and the phases of the elements excitation sources, called sources weights. In traditional antennas arrays, the source control of the radiating elements permit the fields interact in space and construct the resulting diagram format.[5][6] The direction of the main lobe will depend on the relations among sources phases and amplitudes, to satisfy the link necessity. By modifying the element signal amplitude, it is possible to control the radiated power and the communication link length. Fig. 1 shows a system in which the antennas array is formed by L isotropic radiators. Although this type of antenna is not a realizable one, is possible to get the diagram of other structures from an array of isotropic antennas by means of the multiplication diagram principle.[5] To be possible the demanded communication, is necessary to locate the main lobe of the receiving system in direction to desired signal and the diagram nulls must be guided in the directions of the interferences.

As shown in Fig. 1, the complex weights (w_L) make the control on the array radiation diagram.[15] The signals that arrive on the elements, $x(t)$, depend on the angular position of the emitting source and include the noise of the system. For a specified element of array, the received signal can be described as

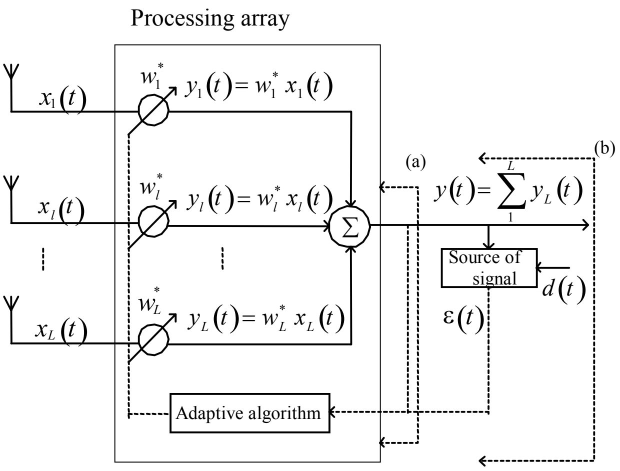

FIGURE 1.
STRUCTURE OF A BEAMFORMER WITH ADJUSTMENTS OF WEIGHTS .

$$x_l(t)=\sum_{\lambda=1}^{L} m_i(t)exp\{i2\pi f_o[t+\tau_\lambda(\phi_i,\theta_i)]\}+n_\lambda(t) \tag{1}$$

where $m_i(t)$ represents a complex envelope, a function of the modulation, depending on communication system type and on access technique, such as the time division multiple access (TDMA), the code division multiple access (CDMA), the frequency division multiple access (FDMA).[14]

The term $n_\lambda(t)$ represents the noise on λ^{th} element of the array. In general, it involves random processes and it is compound by the environment noises and those ones generated in the electronic components of the transmission and reception equipments. It includes the residual noise in the antenna elements in absence of transmitted or received signal. The term $n(t)$ is close to the white noise, with power determined by the system bandwidth and variance.

The wave front delay in one elements of the array, $\tau_\lambda(\phi_i,\theta_i)$, is calculated by

$$\tau_\lambda(\phi_i,\theta_i)=\frac{d}{c}(\lambda-1)\cos(\phi_i,\theta_i) \tag{2}$$

where index i indicates the angular position of i^{th} source of signal in the medium, c is the speed of the electromagnetic wave (3×10^8m/s) and λ is the order of the element of the array. [13] The distance between elements of array (d) is specified in function of the wavelength, usually $d \le \lambda/2$ as form to prevent the increase secondary lobes in the resulting array diagram.

In an environment as the described one, it must be guaranteed that the desired signal is always received and the interferences are reduced to minimum value. For obtaining this performance it is necessary to minimize the average power at output of the beamformer system. This is possible if the weights will satisfy the condition that its products with the position vector of the sources result in a unitary value. As the signals in basic band are represented by complex values, it must be used the conjugated values of the weights to attend this demand.[16] The output of the beamformer system of Fig. 1 are written in the form

$$y(t)=\sum_{l=1}^{L} y_l(t)=\sum_{l=1}^{L} w_l\, x_l(t) \tag{3}$$

Using the matrix notation, (1), (2) and (3) can be write as

$$\mathbf{x}(\mathbf{t})=\begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_L(t) \end{bmatrix} \tag{4}$$

$$\mathbf{w}=\begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_L \end{bmatrix} \tag{5}$$

$$y(t)=\mathbf{w}^H\mathbf{x}(\mathbf{t}) \tag{6}$$

in which H indicate the transposed of the conjugated complex of the array elements weights. The vectors $\mathbf{x}$(t) and $\mathbf{w}$ indicate the signals arriving at the array and the elements weights. The direction vector of desired signal is represented as : [12]

$$\mathbf{a}(\theta_i,\phi_i)=\mathbf{a}_i=\begin{bmatrix} 1 \\ e^{-j\Delta\psi_2(\theta_i,\phi_i)} \\ \vdots \\ e^{-j\Delta\psi_L(\theta_i,\phi_i)} \end{bmatrix} \tag{7}$$

where $\Delta\psi_i(\theta_i,\phi_i)$ is the phase displacement given by

$$\Delta\psi_i(\theta_i,\phi_i)=2\pi f_o\tau_{\lambda,i} \tag{8}$$

The resultant radiation diagram is found by

$$f(\theta,\phi)=\sum_{\lambda=1}^{L} w_\lambda e^{-j\Delta\psi_\lambda(\theta,\phi)} \tag{9}$$

where $f(\theta,\phi)$ it is the array factor, that is, the radiation diagram of an isotropic antennas array. [2][5][6]

IV. ADAPTIVE BEAMFORMER ALGORITHMS

The adaptive algorithms provide a way to optimize the values of the weights to directed the main lobe for the desired signal source. They must adjust the weight values as a function of the position change of desired signal.[12] There are many types of algorithms used in adaptive process. The sampling matrix inversion algorithm (SMI) estimates the weight values as a function of the number of samples of the received signal. The least means square algorithm (LMS) uses a reference signal, or a training sequence, to recognize the signal, determines the error and to achieve the weights adjustments [14]. The scheme of the LMS algorithm is in Fig. 1 with start analysis from the (b) part, where d(t) is the signal reference and ε(t) the error value. The module constant algorithm (CMA) uses a blind adaptation and does not need the reference signal to achieve weight adjustments. They are used in communication systems that have constant envelope signals [1] and its design is shown in Fig. 1, with comments made from the (a) part.

V. COMPUTER SIMULATIONS

In a situation where it is desired the cancellation of interference signal, a computer simulation with the use of the Matlab® program was made. Three sources electromagnetic environment, with two interferences and one desired signal was assumed. The beamformer with four radiating elements was used, as in Fig. 2. The radiation diagram was formed with the null aiming for the positions $\phi_2 = 80^o$ and $\phi_3 = 130^o$, the undesirable signals. The main lobe appoints its maximum to $\phi_1 = 50^o$. The results had been obtained through the program presented in the appendix, elaborated from the equations that define the desired signal direction Fig. 3 shows the radiation diagram in polar coordinates system, normalized with respect to the maximum value. The main lobe was slightly displaced of desired direction , but its null angles are according to directions of undesirable signal sources. The vector weight of the beamformer showed in Fig. 2 is determined through the equations

$$\mathbf{w}^H = \mathbf{e}^T \mathbf{A}^{-1} \qquad (10)$$

$$\mathbf{w}^H = \mathbf{e}^T \mathbf{A}^H \left(\mathbf{A}\,\mathbf{A}^H\right)^{-1} \qquad (11)$$

$$\mathbf{e} = [1 \quad 0 \quad 0\mathrm{K}\ 0_i]^T \qquad (12)$$

$$\mathbf{A} = [\mathbf{a}_0 \quad \mathbf{a}_1 \quad \mathrm{K} \quad \mathbf{a}_i] \qquad (13)$$

where **e** represents the positions of maximum and nulls. The **A** matrix is formed by the direction vectors of the desired and interference signals. [14]

VI. INCREASING SYSTEM CAPACITY

The capacity increase of the system through adaptive antennas can be proven by Shannon's expression. Then, for a channel with bandwidth *B* and additive white Gaussian noise (AWGN), the capacity is

$$C = B\,log_2(1+SNR) \qquad (14)$$

where C represents the transmission rate in bits/s and *SNR* is the signal-to-noise ratio.

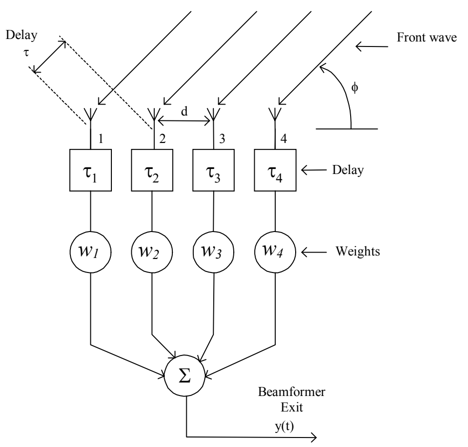

FIGURE 2.
THE BEAMFORMER STRUCTURE WITH NULLS IN DIRECTION OF INTERFERENCE SIGNALS AND THE MAIN LOBE FOR THE DESIRED SIGNAL.

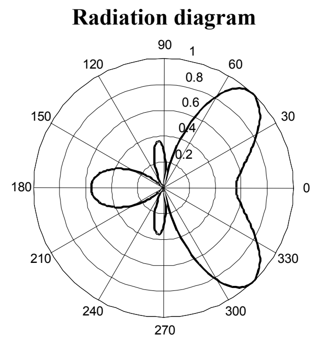

FIGURE 3.
RADIATION DIAGRAM OBTAINED WITH STRUCTURE OF FIG. 2.

In a antennas array with *L* elements, the total power of arrival signal is divided in *L* equal parts and deliver for all channels.[9] Then, the capacity of each channel is

$$C_{ant} = B\,log_2\left(1 + (SNR/L)\right) \qquad (15)$$

and the maximum transmission rate will be the sum of all terms:

$$C = L\,B\,log_2\left(1 + (SNR/L)\right) \qquad (16)$$

Fig. 4 shows the spectrum efficiency, express in bits/s/Hz, as a function of the signal/noise ratio and the number of elements of the array.

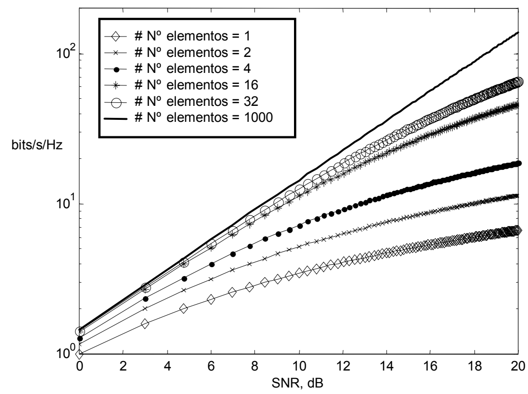

FIGURE 4.
SPECTRUM EFFICIENCY LIMITS AS A FUNCTION OF THE SNR AND THE NUMBER OF RADIATORS ELEMENTS.

VII. CONCLUSIONS

The development of smart antennas has been a very important technology because this system is a possible solution to improve the performance of radio communications link. One of the main applications is in mobile systems in order to provide ways for the solution of problems related to the channel bandwidth, the number of available channels and to cancel interference signals caused for multipath and other sources.

Simulations made in computer prove that with the use of this technology it allows an increase up to 300% in capacity of systems that use the TDMA access technique and up to 500% for CDMA systems.[1] The smart antennas are not restricted to the modulation type or protocol used. It is compatible with all the wireless communication systems. Some companies had carried through exhausting tests in radio-base stations and obtained satisfactory results for several communication systems. [10]-[11]

ECOLOGY IN ENGINEERING EDUCATION

Irina A. Avenarius[1]

Abstract *— Crisis in relationship between nature and society is being increased. Perspectives of humanity development are connected not only with improvements of civilization but also, in a greater extent, with a crucial change of the proper civilization. Future engineer as a promoter of technical progress must realize the need of care towards the nature and our planet. At present many specialists from different areas of knowledge are involved into issues of ecology. The subject of Physical Ecology deals with study of natural and man-made physical phenomena (electromagnetic fields, corpuscular irradiation of the sun, Earth's magnetic field, atmospheric electricity, radioactivity, sound and vibrational oscillations etc.) and their impact on human being. Physics of Environment as a discipline has been developed and delivered in a form of lectures for the students of various engineering specializations.*

Index Terms* — *Ecology, Ecological Physics, environmental protection.

INTRODUCTION

The rapid crisis in the relationship between nature and society is ever growing and it is the education that has a challenge to stop it. The perspectives of humanity development are related not only to a technological improvement of its civilization but also to the crucial change of a proper civilization paradigm as well as to reconstruction of a human spiritual world and to the change of its scale of values. A human being has to change his self-estimation as a conqueror of the nature; now he should strive for being a room-mate of the surrounding world. He has to learn how to secure their mutual evolution and his co-development with the nature [1].

A modern man must learn to see the world in its integrity. A future engineer as a driver of technological progress is obliged in first turn to realize the necessity of his careful attitude towards the nature, our planet, the earth's bowels, atmosphere, rivers, lakes, seas and oceans. It is necessary to inculcate in a future technical specialist from the very first steps of his engineering formation the skills of the right estimation of the impact of his technological solutions on the environmental medium. In this connection, the students of all specialization in MADI Technical University are obliged to attend during one semester the course "Industrial and Transport Ecology" [2].

At present many various specialists are concerned with the issues of ecology: from physicists, chemists, biologists to engineers, lawyers, sociologists, political scientists etc. Studies of physical fields (electromagnetic, acoustic, vibrational) of natural and man-made origins, their influence upon human being and environments constitute the subject of *Physical Ecology* [3].

PHYSICAL ECOLOGY AS A SUBJECT

In 2002, at INTERTECH'2002 Conference in Santos I presented my report about the course *"Ecological Physics"* intended for the students of the 4th year whose future specialization should be *Engineer-Ecologist* [4, 5]. In 2003 the course *"Physics of Environment"* will be presented to your attention. The course has been prepared and delivered by the author to the students of the 2nd year whose specialization is *"Automobile Service"*. Based on concepts of modern Physics, this course is intended to give to the future engineers the notion of natural processes, Earth's properties, its atmosphere, lithosphere, hydrosphere that create the conditions in which the humanity and environments were being developed [5-10].

The syllabus of the course *"Physics of Environment"* is intended for 36 lecture hours. Its structure:

I. Introduction. Backgrounds of Cosmology.
II. Gravitational interaction.
III. Electromagnetic interaction.
IV. Composition and structure of Earth's atmosphere.
V. Contemporary problems of ecology.
VI. Energy pollution of environment.
VII. Conclusion.
VIII. Literature.

In *Introduction* the basic principles of cosmology are given: the Big Bang theory, age, evolution and structure of the universe. The hypotheses of formation of Solar system, planets and their satellites are considered. Data about the planets composition, their densities, masses, distances to the sun and periods of revolution are also given. A problem of mass and angular momentum distribution between the sun and planets is discussed. The physical research methods applied to the universe such as spectrum analysis of celestial objects radiation, Doppler effect for *Red shift*, Hubble's law, hypothesis of expanding or pulsing universe are also considered.

Chapter II deals with gravitational interaction, the law of universal gravity and the Earth's shape. The Earth's gravitational field is considered in the context of its anomalies and variations with the altitude. The gravitational energy of a sphere-like body is calculated. The notion of gravitational radius is then introduced and its value for Earth and Sun calculated as example. The average density observable of the universe gives rise to estimate its gravitational radius. The

[1] Irina Alexandrovna Avenarius, Ph.D., Moscow State Automobile and Roads Institute (MADI Technical University), Leningradski prospekt, 64, Moscow 125829, Russia, zakharov@crdf.ru

latter is compared with its dimensions. A possibility of *black holes* formation and attempts to discover them is a subject for vivid discussions.

The motion of planets and comets is considered in details and Kepler's Laws are derived from equations of motion and equations for angular momentum. The peculiarities of Earth's satellites motion are explained. Here, it is worth saying how the observable trajectories of satellites provide with means to correct the information about the Earth's shape. The influence of Earth's atmosphere on satellite braking is considered. The optimum trajectories of interplanetary cruises as well as the parameters of geocentric orbits for space communication satellites are calculated. The lunar and solar tides on Earth are explained with comparison of their scale and significance. A possibility to build the power station using the energy of tidal waves appears to be a good topic for general discussions. The Earth's nutation is also considered.

One of most interesting topics here is the use of seismic data to study the inner structure of the Earth. It is important to underline here that one of founders of seismology as a science (which was formed at the beginning of the 20th century) was Prince Boris Golitsyn (1862-1916), Russian physicist and geophysicist, Academician of Imperial Academy of Sciences in St. Petersburg. It is explained here that the velocities of longitudinal and transverse waves traveling through the Earth during an earthquake depend on Earth's density. Owing to this fact the Earth's crust, Moho's boundary, Earth's mantle and Earth's inner nucleus have been discovered.

Besides, it is worth discussing the fact that the Earth cannot be treated as an inertial frame of reference because of rotation around its axis and that an introduction of so called *forces of inertia* is necessary to describe the motion of bodies in Earth's reference frame. A centrifugal force of inertia is responsible for change in weight of a body when measured at different latidudes. The force of Coriolis is to be taken into consideration when the motion of rockets, projectiles and air masses of atmosphere are calculated.

Chapter III considers the electromagnetic interaction beginning with the elementary particles classification based on a type of interactions in which the particles participate (photon, leptons, hadrons). A short historical reference is given on the development of knowledge about electric and magnetic phenomena beginning with ancient Greek concepts up to the laws of electrodynamics and quantum mechanics. The development of knowledge about Earth's magnetic field is given in full details. A comparative table for values of magnetic induction of Sun, planets and Moon is given in a context of importance of the magnetic field for life of living things on the Earth. The quantitative parameters to describe the magnetic field are provided (vector of magnetic induction, intensity of magnetic field, its horizontal component, magnetic declination and inclination). The *SI* units of measurement *Tesla (T)* and *Amper/meter (A/m)* are compared with *Gauss* and *Oersted* prevalently used in the past. The hypothesis of the Earth's magnetic field formation is considered. The value for the magnetic induction at poles, equator, middle latitudes are given. As a subject for discussion the issue of the constant component and variations of magnetic field is raised. Brazil (Rio de Janeiro) and Siberia are given as examples of magnetic anomalies. Paleomagnetic measurements, magnetic field inversions, linear magnetic anomalies and a hypothesis about broadening of the oceanic bottom appear as the good subjects for further discussions with students.

Topics about the Earth's electric field begin with quantitative characteristics known from *General Physics* course: intensity and potential of electrostatic field and units of their measurement. The Earth's charge is then calculated starting from known values of the electric field intensity in the vicinity of the Earth. Some values of electric field intensities typical of natural phenomena are given (a good weather field, a field in the channel of lightning electric discharge). The formation of positively and negatively charged ions in the atmosphere is also considered.

This last point leads to the motion of charged particles in electromagnetic fields. Its consideration begins with the equation of motion in stationary electric and magnetic fields under action of Lorentz's force when the parameters of trajectories are calculated. The drift of particles in crossed electric and magnetic fields is also considered with an emphasis that the drift velocity does not depend upon the mass of a particle or its value and sign of charge. The drift in a non-uniform magnetic field is an interesting point which helps to comprehend the action of magnetic mirrors. The Earth's radiation belts and their role in life processes are considered together with the motion of particles in alternating electromagnetic fields.

The differential wave equation is then derived on the basis of Maxwell's equations. The expression for the velocity of an electromagnetic wave in vacuum and in media is given.

The atmosphere's composition and structure are studied taking into account the altitude. It is shown that the presence of troposphere, stratosphere, mesosphere, thermosphere and exosphere is determined by the change of temperature with the altitude. The regions of homosphere and heterosphere are considered in the context of atmosphere's composition. The impact of "small" gases upon the atmosphere's status, weather and climate is discussed. The physical reasons for change of the atmosphere's composition with the altitude in heterosphere find their full explanation. The standard model of Russia's atmosphere serves as an example. Some more complicated formations – ionosphere, magnetosphere and protonosphere – accomplish this topic.

The impact of the Sun on atmosphere's composition and structure is studied together with its astronomic data, its radiation power and temperature of its photosphere, chromosphere and corona. The energy spectrum and absorption bands of Earth's atmosphere together with the indication of absorbent gases are given. The basic laws of heat radiation are also revised (Kirchhoff's, Stefan-Boltzmann's, Wien's shift, Planck's Law of heat radiation). The basic processes of absorption of electromagnetic radiation by the atmosphere are subject for discussions (resonant absorption, photoelectric effect, Compton's effect). The Earth's energy balance is a subject of particular interest. Here we calculate the solar constant, the Earth's temperature and estimate how this temperature is affected by so called "greenhouse" effect.

Next step is the thermodynamic processes in atmosphere. Here we consider how the pressure and the density of air depend upon the altitude (in isothermic and adiabatic approximations). The Boltzmann's formula is then derived. The adiabatic temperature-altitude gradient is calculated and compared with its value obtained experimentally. The thermodynamic stability of the atmosphere is also discussed.

Studies of atmosphere's dynamics are conducted taking into account the action of the force of Coriolis on air streams. The processes of formation of cyclones and anticyclones and of geostrophic wind are explained as well as some traditional historic maritime terms ("roaring forties", "horse latitudes" etc.). The atmosphere's global circulation system is considered (Hadley's cell, Ferrel's cell, polar anticyclone, western transfer, North-Eastern trade-wind). The particular values of energy for powerful tropical cyclones, hurricanes and typhoons are given. The essence of some local winds finds here its physical interpretation and explanation: coastal and seaside breeze, monsoon, mistral. Some attention is paid to meteorological parameters and atmospheric phenomena which determine the physical state of the atmosphere the weather depends on. The climate is considered as "Synthesis of weathers". Then we consider a scheme of a mean radiation and thermal balance of atmosphere and a possibility to predict the weather: beginning from skilled meteorologists of the past and further towards the modern forecasting science based upon mathematical models of atmosphere and ocean. Speaking about models we consider deterministic and statistic methods of calculations. Points of bifurcations are also considered. The problem of global warming takes a particular place in student discussions. All contemporary ecological problems are considered from the point of view of the anthropogenic impact on environment. We consider the "greenhouse" gases of natural and man-made origin in the context of their role in global warming. The Earth's climate is considered in its ambiguity as a subject which may have different stationary states. The solar activity is considered in its action on atmosphere and biosphere.

The ozone problem is taken seriously as one of the most important problems. The following issues are considered in this topic: physical and chemical properties of ozone; absorption of UV radiation by ozone atoms; ozone concentration in the atmosphere; processes of ozone molecules formation and disintegration; chlorine-fluorine carbohydrates and their role; ozone holes. International efforts to decrease atmospheric emission of impurities which disintegrate ozone are presented.

The problem of energy sources is presented as one of the most crucial problems of humanity. For the sake of comparison we present a table of energy values for the following cases:

- gravitational interaction of Earth's particles;
- rotation of Earth;
- heat streams through the Earth's surface;
- Moon's tidal influence;
- earthquakes;
- volcanic eruptions;
- energy of falling rocks and soil erosion, avalanches, tornados, cyclones;
- energy of large power stations;
- energy liberated due to nuclear explosions, rocket start accidents, big fires at oilfields and refineries.

We draw a conclusion that the energy of man-made processes is comparable with that of large geophysical processes. The basic forms of energy influence on environment are brought to light and the ways to solve this problem are considered. The next point is the ways to save energy by means of resources-economy and energy-economy technologies. New cleaner ways to produce energy are considered. In this context we compare the rate of energy produced by power stations of different types: thermoelectric, hydroelectric, atomic. We compare their efficiencies, atmospheric emission, raw materials consumed and prospects for future. Non-traditional sources of energy are also welcome for discussion: solar power engineering (based on photoelectric and thermodynamic transformers and bioconversion of solar energy), wave engineering (with active and passive transformers of wave energy and energy concentrators), tidal power engineering (with its experimental set-up and discussions on advantages and drawbacks of working and anticipated power stations), geothermal power engineering (working stations and their prospects).

Energy pollutions of environment are considered next. Here we consider noise, vibrations, electromagnetic fields and radiations. The elastic waves are studied beginning with the process of propagation of sound oscillations in air. In adiabatic approximation the differential wave equation is derived and the dependence of velocity of elastic waves in a gas on pressure and density is determined. The notion of sound pressure is introduced and its relationship with the vibrational velocity of medium's particles is established. The energy carried by an elastic wave is then calculated and Umov's vector introduced. The intensity of sound wave is then expressed via the sound pressure amplitude and the amplitude of vibrational velocity. Other relevant issues are specific acoustic resistance of a gas, Law of Weber-Fechner, level of sound loudness and units of its measurement, limits of sound audibility and sensation of pain. Some examples of sounds having different levels of intensity are given. A problem of human ear sensibility with relation to different frequencies is discussed and the level of sound pressure (in *A* scale, *dBA* units) estimated. Other kinds of sound noise are also considered.

Next topic is man-made electromagnetic fields and radiations including their impact on human health. A particular accent is made on using cellular telephones. Some means of effective protection are considered. The ionizing radiation (UV, X and radioactive sources) are considered in the context of their impact on human health (ionizing activity, dosimetry, units of measurement, radiation background etc.).

The "grand total" is in the conclusion of the course: collective knowledge is necessary to solve the ecological problems on the Earth and it is the engineers who are to solve this problem.

THE USE OF OPEN AND DISTANCE EDUCATION IN FACILITATING CHANGES IN MANAGERIAL DEVELOPMENT: THE MEXICO EXPERIENCE

José Gpe. Vargas Hernández[1]

Abstract — *This paper examines influences resulting in changes in managerial training and development with particular reference to the University of Guadalajara, Mexico. It starts by examining conditions at the macro and micro levels that bring about change, the nature of change, and the present and future education and training implications to increasing demands on management within diverse organizational environments that are becoming more complex and uncertain. Technology is playing an increasing role in management education and training. Through the use of open and distance education technology learners have greater flexibility of time and place of learning. In addition, where transdisciplinary approaches are used it is leading to the development of "new types of managers" with abilities, behaviors and values that better enable them to cope. Examples draw on management training institutes in Mexico.*

Index Terms — *Facilitating changes, Managerial development, México, Open and distance education*

INTRODUCCIÓN

A sign of the current times is the continuous change, which is modifying everything. This constant change drags the transition of modern organizations toward the manifestations of posmodernity, which are expressed in individual behaviors integrated by means of technological processes in the same structures. Two new variables enter in scene to define the posmodernity of organizations: their complexity and uncertainty of environments in which they are immersed.

The pace of this dramatic organizational change accelerates exponentially every time. It leaves as a a consequence an enormous human insecurity in the face of structural rigidity of economic, social, political and cultural institutions. These institutions are unable to absorb uncertainty derived from changes, hinder instead of facilitating adaptability of people and also hinder the use of benefits. These benefits can be derived from the great wave of technological revolution of information, which has become a self-transforming movement and transformer of development opportunities and human progress. Although these opportunities are increased it is also evident the increase of threatening phenomena which deepen the feelings of human fragility and insecurity. These propitiate the uncertainty that encourages the traps and dangers of mankind survival.

THE MANAGER OF THE FUTURE, THE FUTURE OF MANAGEMENT

The problem of that, as much the individuals as the organizations take advantage of the opportunities that provide this pace of accelerated change, it is reduced to its control and handling. It finds its foundation in the premise of planning changes, as the theoretical sustenance of organization development that aspire to the transition toward the new times marked by posmodernity. Organizational transitions respond to the current expressions of tendencies toward the globalization and internationalization of the markets.

TABLE I

In this diagram it is summarized some ways in which the future can be visualized:

MACRO	MICRO	FUTURE IMPLICATIONS
Changes in the global environment of the business community are the result of:	Impact on individual managers which leads to:	Alternative approaches to managers:
Productivity improvement of business.	Overload of information Demand for a greater continued absorption of knowledge	Local continued education/ Formal/informal distance learning
Globalization of Business relations	Time compression	More concentration on personal Development.
Economic and Technological Changes	Fast changes of of leadership and organizational fluid styles	Changes in careers Early retirements
Turbulence	Change requirements for administrative staff. Bigger and earlier Responsibilities	Reduced activity / without movement.

[1] José Gpe. Vargas Hernández. Posgrado e Investigación. Centro Universitario del Sur. Universidad de Guadalajara. Prol. Colón SN. Cd. Guzmán, Jalisco, 49000, México. Telefax: +52 341 41 25189. E-mail: jvargas@cusur.udg.mx

These trends have appropriated the advances that the technological-computer science revolution provides. Meanwhile, society is more active, more participating and more demanding of better conditions. There are nowadays, bigger demands for human development and quality of life, greater social justice, formation of cultures that respect diversities, propitiate its solidarity and recognize the human rights.

Professional development in management takes into consideration not only, the emphasis of traditional curricula oriented toward assimilation of knowledge in administrative technology, but also development of the abilities, skills and required competencies for instrumental implementation of changes. But above all, a professional manager development that responds efficiently with attitudes and values as a foundation of practices to face the challenges demanded and required by derived situations of an environment characterized as complex and uncertain.

Instead of developing their work –doing it better, to end up being more experts and able – the managers will have to be achievers. They will be able to look for and to command resources, to determine strategies and to break limitations for implementing them. Instead of concentrating on the consistent use of management systems, company policies and rules, and to focus on high standards, they become operative: operators with a group of values, principles and models, but operators in spite of everything, motivated by will and ability to achieve.

Is it reasonable to ask, "to achieve what"? But the answer to this rests in the future; this future that, without a doubt, will it include the means to make better use of any available resource for us, to improve the quality of life, and therefore our growth and development. The manager of the future clearly has to be, like it was said previously, a good operator, a motivated person that can obtain and to control class resources to achieve results, a highly developed administrator and highly self-confident.

This person can be among the graduate of high ranks at universities. Until universities again can teach an action theory, it cannot be found this developed human being, in such a way that it has to be developed. In other words, the development of managers will become, much more than a necessity of survival as it is now.

To speak of manager development implies a change in education, in such a way that this is the result of experiences, not training of the memory. Education will be a creative-innovative process, (that some futurologists identify as the characteristic feature of a new phase of the technological revolution that we live in our days) in which the manager is able to develop trust, ideas, communication and interaction.

The Japanese Companies take to practice the following process, according to Raymond [1].

- **What have learned and toward where it can take this knowledge.**
- **How the previous knowledge could be incorporate and to be applied to the mark of a new position.**
- **How it can improve a new situation when continuing ahead.**

This process should also be incorporated to our organizations, because with it not only is learning continuously, but rather also it is a process of thinking and increasing the knowledge foundations, all the time, as well as applying new knowledge to the same one, and advancing toward the leadership. The above-mentioned helps us to manifest that the education should exist for the reality and for the future.

From an organizational point of view it is necessary to have, a bigger demand of administrators who will be able to cooperate, and therefore, with abilities of leadership. From the individual point of view, the manager will have more up to date knowledge.

As it was previously signaled, it is evident the existence of unavoidable revolution in managerial practices that have global impacts and that modify all the organizational variables: behaviors, structures and technologies. The current generation of professional managers has been called to be educated in the "keyboards".

One of the many ways to increase the wealth of those administrative practices, are the learning outlines at distance which have been developing some universities and other institutions until the level where the abilities and competencies of management can be self-taught. With the use of special text materials, exercises, videotaped examples, use of electronic mail and platforms, the learning responsibility can be broadly transferred. Experiments have shown that the tutor's contact can be designated successfully outside of the programs and that the assignments of tasks can be determined in such a way that a self-assessment and self-evaluation is possible.

With implementation of telematics, education was adapted to the constant change operating in organizations, giving place in this way, that education process does not center around the previously established relationships between the teacher and the student. Thus, more emphasis is given to the link between the information that receives the student and the same student. In this form, the learning process is redefined.

Lack of personal interaction can be a deficiency, but at the same time can be replaced by more modern techniques of interactive video. This allows the student to interact in managerial events on the screen and then to ask, to explore, to answer and to make decisions watching the results of his conclusions displayed in front of him. This is similar to a flight simulator where the training pilots can prove their flight skills without risking. The manager can prove different methods in any kind of problem without being exposed, in a short period of time and space.

With distance learning education, transfer of control of teaching-learning process is given to the individual; this decides what he/she needs to know and then he/she makes the best use in the available learning resources for him.

When being developed continuous education technology it is impelled more and more and designed by the individual adapting it to his own desires and necessities, motivating this way his self-development. Some approaches of this self-development are beginning to emerge. These novel education developments at distance are operated on global bases. Education institutions at distance learning will win, when having an audience in the entire world, but they will have to continue being linked with this audience of foreign countries, by means of consultants.

Of course, one in the best ways of learning at the present time, is doing it. A little less drastic are the outlines of active learning, where the executives either manage special projects inside their own areas or in any other part as a planned process of performance. These outlines that have been with us for several years, also have the advantage of the project's value and the test of managers' audacity. These projects can involve individual action or to lead to a team project, usually of a multidisciplinary nature.

In the past, the time taken to obtain experience and maturity has made to management a field of older men whose energy and forces of creativity weakening are inevitably. One only has to look back, to see that the young men have been able to create when an opportunity has arrived to people of great talent. The executive professional youths, with an urban culture, trained in private universities, also well-known as the " yuppies ", they are those that more quickly are assimilating the technological advances and incorporating them to the directive and managerial practices of the organizations.

To be in agreement with the current changes, organizations not only should incorporate to technology but rather the individuals will have a change in mentality as a change in organizational relationships and it will be a change in the managerial style. The incorporation of technology to the directive and managerial practices and the use of the telematic, make possible that organizations structure their administrative outlines in agreement with the necessities and socioeconomic conditions of the country. With this practice, it should improve the competitive position to the international level. The above-mentioned has given as a result the linking of the administrating and managerial professionals with the productive and social sectors.

CONCLUSION

Concluding, the managers of the future will have to be agents of development of those organizations to which they are integrated. They will be creative and innovative leaders with clear conciousnes and awareness of their social responsibility, with a strong discipline of work, with a high level academic development, and that they know how to appreciate cultural and social values of diverse countries.

HYBRID GENERATION OF COLLABORATIVE LEARNING OBJECTS IN PIAGET

Ismar Frango Silveira[1], Maria Alice Grigas Varella Ferreira [2]

Abstract *— This work discuss the process of hybrid authoring of pedagogical content over PIAGET (Platform-Independent, Adaptive, Generic Environment for Teaching), a three-dimensional tool used in distance learning projects that involve knowledge building based on social interactions. More than a virtual environment for three-dimensional chatting with avatars, PIAGET combines several kinds of interaction in a way that virtually simulates many of the more frequent real interactions among teachers, apprentices and the objects inside a virtual classroom. Through a distributed virtual reality environment, PIAGET allows teachers and students to generate learning objects – like solids, blackboard or notebooks - in a hybrid, collaborative way, while they interact among them and with such objects as they were in a real classroom.*

Index Terms — Collaborative Learning, Distributed Objects, 3D Interfaces, Hybrid Authoring.

INTRODUCTION

When analyzing actual tools that can be used to support collaborative learning process over a multi-user, networked environment, it can be seen that the greater part of them consists into toolkits for building or managing pre-built, usually static, pedagogical content. In some cases, these toolkits reach very high degrees of completeness, in order that they can supply a very large range of academic management services that go since statistical control of page views – that can be used, for instance, to measure the specific points of the pedagogical content that had received more visits, through a large quantity of tools for e-evaluation and videoconferencing, among others.

However, two points deserve deeper discussions: first, the lack of interaction possibilities on these tools, since they barely go beyond chat or videoconferencing as the unique ways of doing synchronous collaboration. Second, even though they usually support a wide range of new technologies, they are commonly used to support static content that are the basis for expositive pedagogical strategies, rarely supporting interaction-based ones, like constructivism.

In this paper, it will be shown how a tool with a different approach of interaction can be used in order to support the process of hybrid authoring when building and managing pedagogical content. It is organized as follows: the next section will present an overall view of PIAGET. Following, the authoring processes will be discussed, detailing the hybrid authoring process as an extension of static and dynamic authoring. To conclude, a brief explanation about PIAGET's learning objects will take place, as well as some final considerations.

PIAGET

PIAGET [4][5][6][7] stands for Platform-Independent, Adaptive and Generic Environment for Teaching, being an inter-institutional project that consists in building a three-dimensional, distributed environment for using on a distance learning context.

Some kinds of interaction that are usually taken in a classroom are very diffuclt to be metaphorized onto a bidimensional screen, specially those ones that are based on three-dimensional elements whose manipulation might be essential for some teaching-learning context. This fact can be verified in common real situations that can vary from architecture, where students are meant to exchange scale models, through medicine, in those situations that require corpse manipulation in anatomy classes. These kinds of element, in fact, are very hard to be represented in a HTML document. Therefore, their creation, manipulation and sharing are features even difficult to be achieved.

Although some sollutions might be designed over proprietary techonologies, or even using open standars, like VRML, most of them are *ad hoc*, even if they are very effective in doing what they are meant to do. Besides, these technologies and standards usually fails in providing a multiuser, multiplatform solution.

PIAGET represents a solution that try to solve some of these problems, in order that it represents a proposal for a platform for interaction through a three-dimensional, multi-user interface built over a distributed objects-based architecture.

CONTENT AUTHORING

Since knowledge building process involves far more aspects than simply to accumulate pedagogical content, the manner by which content's authoring process is done can either limit or extend the range of pedagogical possibilities of its use.

There are different ways to classify the authoring proccess. In this work, we will consider the classifications according to creation, presentation and sharing of pedagogical content.

[1] Ismar Frango Silveira, Universidade Cruzeiro do Sul, Av. Dr. Ussiel Cirilo, 225, 08060-070, Sao Paulo, Brazil, ismarfrango@uol.com.br
[2] Maria Alice Grigas Varella Ferreira, Universidade de Sao Paulo – Escola Politecnica.

Classical hypermedia systems tend to supply a very large range of toolkits for elaborating pedagogical content, often with high levels of elaboration and detail. Nowadays, this fact can be easily observed since the adoption of DHTML standard, with the use of layers, CSS, Javascript and Java, besides a vary of proprietary technologies that are meant to bring a greater kind of interaction in a user-friendly way. However, these tools barely offer interaction means enough in order to fullfill all the requirements CSCL systems usually have.

By means of its creation, pedagogical content can be basically built over three different ways of authoring. First, the static authoring, that names all content that is usually pre-built, often over an HTML basis, using or not supporting tools for this task. Such kind of content is surely the most used for building and deploying of web-based pedagogical content. Even though its spread use, the main problem with static content lies on the fact that it supports a classical, expositive pedagogical strategy, under which the student is meant to follow a guided tour or indexed schema to browse the contents that are exposed to him, and from this he is expected to built his own knowledge.

Figure 1, extracted from [1], presents an UML Use-case diagram that shows the roles that are played by actors when doing static authoring of pedagogical content.

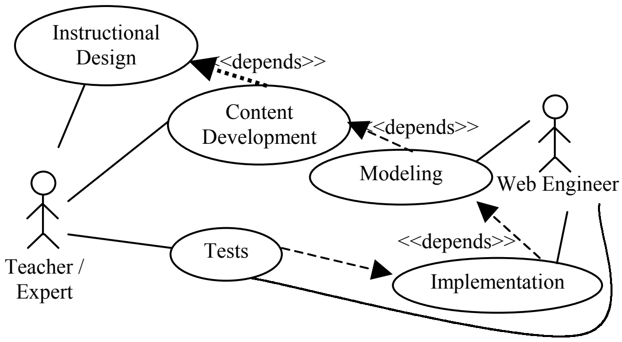

FIGURE. 1
USE-CASE DIAGRAM FOR STATIC AUTHORING

It must be noted how such diagram preserves some characteristics that are common to classical process of Experts Systems modeling: the Teacher -which plays the Expert's role- is responsible for the use cases related to the Instructional Design [10], the Content Development and Tests. Moreover, the Web Engineer has as responsibilities to model and implement that content developed by the Teacher, also acting in the Tests use case.

In other hand, we have those contents that are generated while the interaction among students, like chat sessions, or even some content that are created generally from reasoning about some subject, e.g., forum messages and mails exchanged in a group. All these content must be also considered as a part of the course's content, since it is referred to an externalizable part of knowledge building process. This way of obtaining new, on-demand content is named dynamic authoring, and a use-case diagram that contains the actors and the roles played by them during the dynamic authoring process is shown on Figure 2.

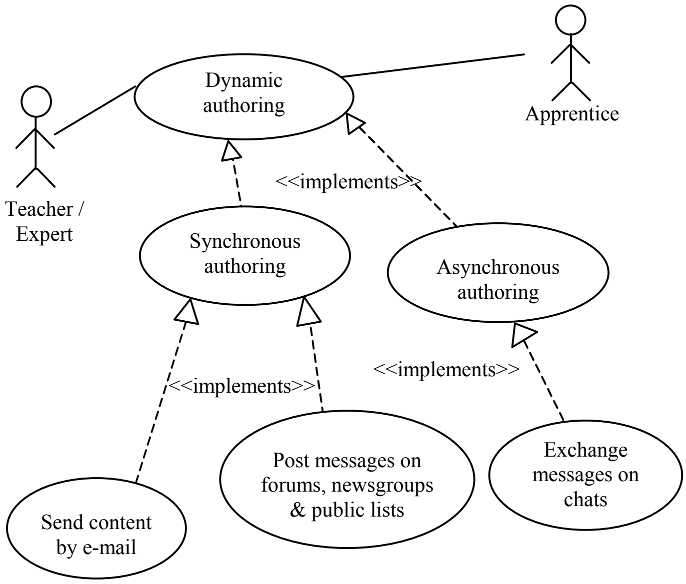

FIGURE. 2
USE-CASE DIAGRAM FOR DYNAMIC AUTHORING

The thoughts of Jean Piaget [8] reinforced the need for knowledge building by own, but this building was intended to be done through the interaction among students and subject. In other hand, Lev Vygotsky [9] proposed that such building must be taken through social interaction among learning agents. Based on this, the PIAGET Project is meant to support inter-agents interactions, as well as interactions among learning agents and learning objects or even agent-environment interactions. Clearly, those interactions would only have meaning under an authoring scenario that supports dynamic content..

In spite of the importance of this sort of knowledge, which reflects the way the information that is given to the students is transformed into knowledge, some supporting tools for learning do not comprise it as a part of the formal content for a given course. This is more evident on exposition-based learning programs, since interaction among students is not an important matter to these programs.

The hybrid authoring is achieved when dynamic authoring can be done over static, commonly pre-built, pre-deployed content. However, this way of authoring also includes the dynamic insertion of new content into some learning context.

This kind of authoring is generally obtained by mixing classic static authoring tools with CSCL systems in order to allow the organization and management of pedagogical content, integrating static and dynamic content in a well-structured, concise context.

However, it must be pointed that hybrid authoring is not solely a sort of juxtaposing of static and dynamic authoring, since this kind of authoring brings new possibilities referred to the collaboration among learning agents through the sharing of learning objects. Figure 3 shows a scenario for dynamic authoring, in which static and dynamic authoring whole scenarios are encapsulated into single use cases, in order to assure more clearness.

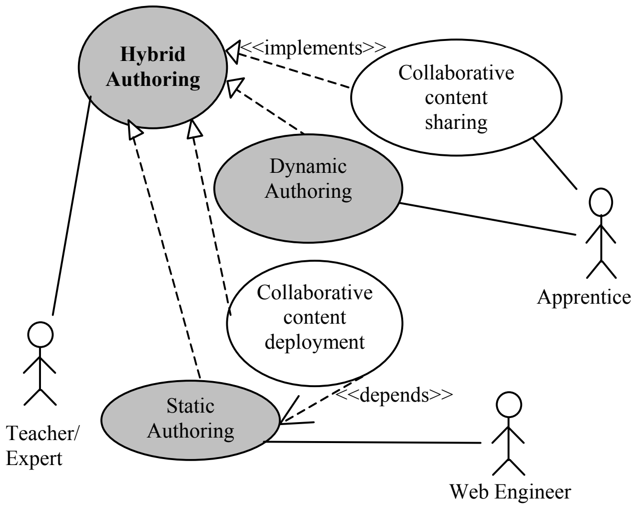

FIGURE 3
USE-CASE DIAGRAM FOR HYBRID AUTHORING

Another way to classify authoring is according to the content's presentation. In a more general way, authoring can be done even over a textual basis, involving or not graphical user interfaces. (Here, it is necessary to point that the content is meant to be textual, not the tools for doing it under this kind of authoring.)

Most of the available contents nowadays are deployed over two-dimensional, WIMP user interfaces [3], largely using hypermedia resources. PIAGET, however, brings a mixed proposal of a WIMP-based interface to control a three-dimensional world that serves as environment where interaction among learning agents might occur. The reason for mixing two distinct paradigms together was based in a Jakob Nielsen's article [2], in which he points the lack of expertise students and teachers have about manipulating a 3D interface with non-appropriated devices, like mouse and screen, as limiters to the possibilities of using a whole three-dimensional interface for interaction systems. The interface that was used for early PIAGET versions [4] had to have some of their 3-D related metaphors translated to button-triggered actions in order to improve the users' performance, since the metaphors being used seemed barely familiar to students, since it diverged from classical WIMP standard. Figure 4, adapted from shows this mixed-mode interface through a screenshot of PIAGET.

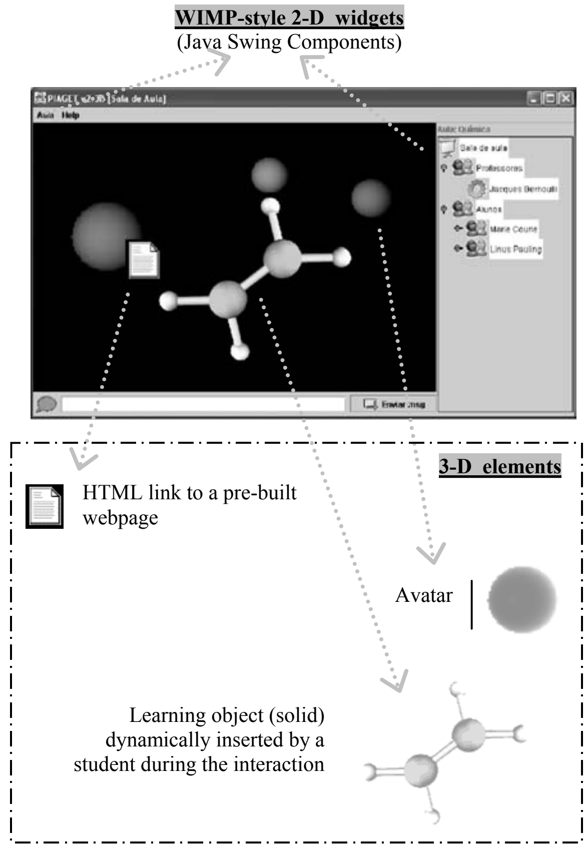

FIGURE 4
MIXED-MODE PIAGET'S INTERFACE

Figure 4 showed a screenshot of PIAGET, with some avatars, representing learning agents sharing a learning object during a chemistry class. The use of three-dimensional metaphors to represent learning objects is based on the fact that some kinds of learning objects are intrinsically better represented by three-dimensional elements that can be handled and shared by learning agents.

Collaboration is another way for authoring classification. It could be said that static authoring would lead to a non-collaborative authoring, but collaboration can occur beyond computers' limits, since a group of teachers can collaborate among themselves in order to elaborate pedagogical content.

However, by means of collaboration through a networked, computer-based environment, authoring can be done in ways that goes from stand-alone authoring, which means no collaboration at all, through collaborative authoring in a bi or even multilateral way.

Figure 5 shows an "authoring cube", which is used for classifying collaborative learning systems according to the authoring processes supported by them.

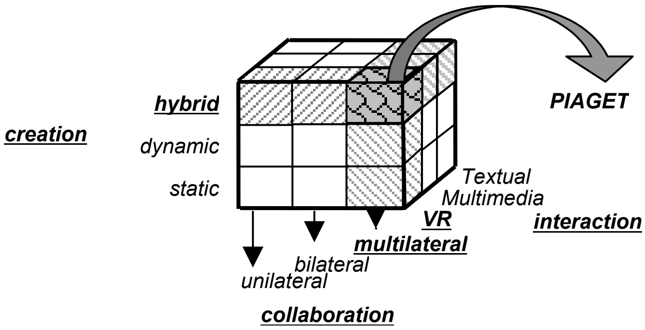

FIGURE 5
AUTHORING CUBE

Although the term "collaboration" might be interpreted in several ways, it is not meant to be a synchronous task, in order that it can be done in an asynchronous mode. In this paper, we will consider as collaborative learning every task of knowledge building that is done by two or more learning agents over learning objects shared through the learning environment.

PIAGET'S LEARNING OBJECTS

In PIAGET, every learning agent can contribute with their own learning objects, which can be pre-built content or some kind of content made on-the-fly. The PIAGET's metaphor set contains representations for the following allowed learning objects:

- *Image2D* objects, representing two-dimensional raw images that can be inserted into the three-dimensional world (normally as textures for thin rectangle parallelepipeds), and thus shared among the learning agents.
- *Solid* objects, which are three-dimensional elements (Java3D objects, VRML worlds or another supported format). PIAGET interface has some resources for their handling –rotation, translation, zooming, etc., although its execution might demand some kind of expertise when used with improper devices. It is important to note that, since PIAGET's architecture was built in a high level of abstraction, it is completely device-independent.
- *Blackboard* is a teacher's exclusive object, representing a metaphor for a place where teachers – or another learning agent with similar permissions- place pre-built content. A Blackboard object is merely a metaphor for representing a place where content is placed by the teacher, being a container for other objects with a more refined control over their sharing.
- *Register* is an object that represents annotations done by teacher during the interaction time, with limitations for sharing – it can be shared only among teachers, and is not visible by students.
- *Notebook*, which represents personal annotations done by students, which can be shared among another learning agents. A notebook is also a container for other learning objects.
- *Message* objects represent textual messages that are exchanged during interaction time. A set of all Message objects that are created during a virtual class can be serialized for a better control.

Since PIAGET's architecture is completely open-source, more learning objects can be added to the metaphor set simply using inheritance, given that its basis are entirely object-oriented. In fact, the ability for expansion can be seen at any tier of its architecture, since its interface, until the data tier. More details about PIAGET architecture can be seen at [5] and [7].

CONCLUSIONS

This work presented hybrid authoring of pedagogical content as a way to support collaborative learning through the use of PIAGET, a three-dimensional tool that is meant to cover a representative range of the steps that are taken for knowledge building.
Hybrid collaborative authoring process is expected to cover the most important aspects of social interaction that commonly occurs in a physical classroom, which is reached by the simulation of those interactions, at the same time that the possibilities for such interactions can be expanded at a limit imposed only by virtual reality technological issues.
At the moment this article had been written, PIAGET was being implemented with some beta-releases being tested under controlled situations. Therefore, future works points to a continuous optimization of PIAGET, which includes the use of ontology for managing large quantities of learning objects that can be shared in a real learning situation.

A HIGHLY INNOVATIVE MODEL FOR EDUCATION IN ENGINEERING AND APPLIED SCIENCES

M. Kemal Inan[1]

Abstract — *Sabancı University is a private university funded by one of the largest industrial holdings in Turkey. It is ranked within the first top five universities of Turkey. The university structure and mission was meticulously planned since 1994 and the university started its undergraduate and graduate education in 1999. In this paper some of the innovative features of Faculty of Engineering and Natural Sciences are described in the context of our overall educational system, university infrastructure and the preliminary results observed within the first three years of our undergraduate and graduate education and research experience. Among the novel features is a flat faculty administrative organisation (no departments) that offers undergraduate and graduate programs mostly in information technology related areas as well as molecular biology and materials sciences. Absence of departmental separation greatly enhances the interactivity required for cross-disciplinary communications in teaching and research. Other features include liberally oriented program curriculums allowing the students a much greater space for choice and facilities that enable students to get involved in independent and hands-on project work throughout their education.*
Index Terms — Innovative university, engineering education, higher education in Turkey, liberal curriccula in science and engineering

INTRODUCTION

This paper describes a new and innovative private university with a meticulously architectured and well-equipped campus placed at the outskirts of Istanbul, Turkey. In order to appreciate the innovative aspects of Sabancı University it is important to understand the prevailing higher education system in Turkey the outline of which we present in the next section. Following that we describe the initial conception and the underlying structure of the Sabancı University. In the section on operational aspects we first describe some positive observations mostly involving the Faculty of Engineering and Natural Sciences and then discuss some problematic areas that await solutions. A few thoughts on future prospects are given in the conclusion .

THE CONTEXT : HIGHER EDUCATION IN TURKEY

According to *The Word Almanac 2000* percentage of population at or below age 19 in Turkey – with a total population of 67 million - is 38.5. The world average is 38.9 whereas the figures for the developed and less developed world are 24.8 and 42.2 respectively. The social and political context of having a relatively higher percentage of younger population becomes clear when it is contrasted to the average figure for Europe which is 24.1. Hence if education at all levels and contexts – i.e. primary, secondary, higher,vocational, other professional such as IT etc. – are taken seriously this demographic property can be turned into an advantage : if the context is taken as formal or de facto integration of Turkey into Europe then a relatively educated younger population means a driving human resource much needed by Europe. This is why education in general and higher education in particular has an immediate strategic significance for Turkey.

Turkey has 74 universities out of which 53 are public and 21 are privately governed. All universities, be they public or private, are tightly coordinated by a highly centralized bureaucracy, *Higher Education Authority* (**HEA**) according to the dictates of an one-size-fits-all higher education law. One arm of the **HEA** is the *Student Selection and Placement Board* (**SSPB**) which is responsible for organizing a centrally managed student placement examination given every year simultaneously at selected number of locations both inside and outside Turkey. New as well as old high school graduates - students attempting another go for a desired place in a university - take the exam. The number entering is approximately 1.5 million and over 10-15 %, including open education positions, are admitted to a program in a department in one of the 74 national universities. The logic of placement is that of supply and demand. In simplified terms each student specifies a priority list among available programs offered by the universities ; each university department announces its quota of student intake and the rest is an automated calculation based on these data and the points scored by the students computed according to a rather complex formula taking into account student's exam performance and individual high school standing with adjustments that take into account historical performance record of the school in past entrance exams.

[1] M. Kemal Inan, Dean of the Faculty of Engineering and Natural Sciences, Sabancı University, 81474 Tuzla , Istanbul,Turkey, inan@sabanciuniv.edu

Possibly owing to a high degree of automation it is a fact that the central entrance examination managed by the **SSBP** enjoys the prestige of being free of corruption where no form of clientalism has ever succeeded in distorting the placement order of this automated process. On the other hand it has still been subject to criticisms on two accounts: the lack of social justice in the selection process; and the validity of the test evaluation system judged by the correlation between the student placement scores and their later academic performance. The social justice aspect is a problem to be solved on a different platform and thus we shall not dwell on it here. Much research has been performed on the scientific evaluation merits of the system and there seems to be some correlation with academic success especially on top echelons of performance. Yet the criticism can be radicalized in a way that calls into question the centralized process of selection judged by its negative influence on the entire secondary education. We elaborate on this below since it bears relevance to some of the innovative features of Sabancı University.

Higher education has become of great concern globally since it implies access to well-paid jobs, a commodity that is becoming more and more scarce in an age of radical automation. In addition to the economic benefits, university education is also an important status symbol in Turkey and a good university education will secure a highly respected social position as well as a good job. Consequently the competition to acquire a decent place in a high rated university has generated a sizable commercial industry of enterprises coaching the students to perform well in the test-style entrance examination. The skills involved for a successful performance are based on categorizing possible test questions in mathematics and sciences into a number of types and subjecting the students to drills on solving problems through exhausting all types. Social sciences are no exception to this approach since Turkish secondary education in social sciences has a high doze of nationalistic indoctrination which makes the contents suitable for rote memorization based on text books approved by the ministry of education. These observations have some serious consequences discussed below.

The commercialized university entrance examination market has damaged Turkish secondary education in radical ways. Students, during their last two – if not three – years in high school focus entirely on university entrance activities by choosing and attending one of the private preparatory coaching courses. The high schools, even the most reputable ones, accept this as a fact of life and simply support the students in their extra-curricular preparation activities instead of supplying them with a rigorous secondary education.

The necessary skills for solving test questions have little to do with the requirements of contemporary higher education. Nor are they related to a good secondary education. Among the qualities that lack in most high school graduates are *literacy*, *purpose guided socialization* and *hands-on experimentation* as explained in the following paragraphs.

- In general students do not possess the oral and written comprehension and self-expression skills even in their native language of Turkish, leaving aside extending those skills for a universally valid language like English.
- Students have little or no exposure to working in simple team projects whereby a group of participators organize themselves to shape a loosely defined project topic into an operational program. In such an exercise the students learn something about leadership, initiation and communication.
- Finally students lack a sense of hands-on experimentation, an important preparatory step in *learning by doing*. For example carefully designed laboratory experiments orient the youngsters to professions in science or engineering or exposure to computers orient them to professions in information technologies.

On the positive side let us, nevertheless, admit one useful attribute that all Turkish students possess before they enter a university: a strong sense of self-guidance and a fighting spirit for survival in a competitive environment.

Before we move onto the next section it is important to mention two distinct peculiarities, one linguistic the other professional, of the Turkish higher education.

In the 50'ies Turkey had a few universities which were structured in the German style where professors occupied chairs and younger faculty members did not have the authority to teach or supervise research work independently. After the founding of a new state university in 1956, the Middle East Technical University (**METU**), the entire Turkish university system gradually transformed into an US-like system. **METU** was the first example of a purely national – as opposed to foreign missionary based schools carrying over from the 19th century - education institute whose official language of teaching and research was English. Adoption of English as the official operational language of **METU** had an immediate practical consequence: students after completing a one year preparatory language course attended university courses in which internationally accepted text books were used which eliminated the necessity and dangers of being bound to a Professor's possibly outmoded notes or books in Turkish. The access to a large number of resources in English gave the students a self-confidence which culminated in a different culture and attitude of graduates coming from

METU. All of this survived among heavy criticism on grounds of cultural degeneracy. Adopting a foreign language was taken an insult to the national pride. Yet there was no viable example of any educational institute that could successfully teach professional courses in the national language and teach enough English on the side as, for example, practiced in the Scandinavian countries. The national pride criticism continue to date though with much less influence since after the example of METU the new understanding kept on proliferating. The **top** ranked five universities of Turkey perform all academic activities, including teaching, in English. This is a remarkable and unique example of cultural pragmatism with a bottom-up support in a country without a colonial past under British Empire or any other English-speaking power.

Three areas that are extremely popular in Turkey are electrical engineering, computer science and industrial engineering. According to the 2002 entrance examination statistics, students who were accepted to the departments of the top five universities offering programs in these areas come from the top 1% of those accepted to universities. Even for low rated universities in less developed regions where quality of education is questionable, students accepted to these high demand departments are in the top 10-15%. This shows an overwhelming concentration of demand for a small number of areas mostly in engineering. Other relatively high demand areas are management and economics,molecular biology and medicine. Demand for mathematics, pure sciences and social sciences are lower except for a very limited number of positions in some elite private universities that offer scholarships.

Two important conclusions can be drawn from the observations above. The first is that the demand for higher education in Turkey fits international job markets of the developed world. That is, a work force that consists of fluent English speakers trained in information technologies and other technological areas for which there is definite shortage in regions like Europe and US. This probably is no coincidence since a great number of university graduates from Turkey in these areas fill up graduate schools or silicon valley jobs in the US. The second conclusion is that this collective demand pattern overrides individual tastes or concerns of the students in choosing professions. A gifted student choosing a low demand area, such as say psychology, is viewed as an anomaly and a waste of the gift. Advisers in coaching enterprises have been successful in generating an environment in which students are already conditioned to choose areas and universities compatible with their performance.

THE FOUNDING PRINCIPLES AND STRUCTURE OF THE SABANCI UNIVERSITY

Sabancı University was officially founded – by law like all the other universities – in 1997 and started its undergraduate and some of its graduate programs in 1999. The principal investment and operational funding comes from a foundation of Sabancı Holding, one of the two largest private industrial holdings - both of which are family owned - of Turkey.

The university is composed of three faculties : Faculty of Engineering and Natural Sciences (**FENS**), Faculty of Arts and Social Sciences (**FASS**) and Graduate School of Management (**GSM**). Together with an undergraduate program in management sciences to be offered next academic year there are 12 undergraduate programs, 7 out of which are offered by **FENS**. These are: *microelectronics, telecommunications, computer science, mechatronics, industrial engineering, genetics (molecular biology) and materials science*. In addition to undergraduate programs there are graduate (MS and PhD) programs offered by the three faculties. **FENS** academic graduate programs are: electronics engineering and computer science (an integration of the first four **FENS** undergraduate programs stated above), materials science, molecular biology, industrial engineering and mathematics. In addition **FENS** offers two professional masters programs, one in IT and the other a industry sponsored double degree program in a field of engineering and management with the collaboration of **GSM**. The size of the university is small: first stage planning targets a total number of 3500 students - including the graduate students which will constitute 15-20% of the total. This target is expected to be reached in 2007. The campus is built on an area of 900 acres with 10 large buildings and a small artificial lake.

The actual planning of the university formally started in 1994 and in 1995 an international search conference was held with participants from 25 countries ranging from academicians, technocrats, businessmen to students and parents. The purpose of the search conference was to brainstorm in order to generate an outline of the founding principals of a university for the 21st century. There were no constraints or preconceptions other than the fact that the university was to be built in the outskirts of the 1500 year old city of Istanbul. Much of the innovative aspects, which we discuss next, of the Sabancı University has its origins in this search conference.

Sabancı University enjoys a *departmentless* system. That is, there are no formal administrative units under the faculties. This puts some additional load on the faculty deans where an informal and flexible delegation is used for coordinating activities like the academic programs. The existing faculty sizes have rendered this arrangement of flat organization administratively manageable. On the other hand the advantages have already began to reap their fruits. Recent internal projects such as using liquid carbon dioxide as a coolant in high-speed machine tooling or synthesizing micro-surfaces for automated biological sample analysis are just a few examples of research collaboration between materials science, mechatronics and biology disciplines. What is, however, more important is the multidisciplinary atmosphere of the **FENS** building within which the students get educated and do research. **FENS** building is the largest building in the campus that occupies 17500 meters squared of space with over 50 research labs, auditoriums and classrooms and faculty and graduate student offices. To take a striking example consider a biology student that is constantly in *contact* with students in computer science mechatronics, electrical engineering, materials science or mathematics. By the word *contact* we mean sharing common elective courses, participating in common informal discussions, participating in undergraduate or graduate projects possibly of interdisciplinary nature etc. This is a remarkable feature that is non-existent in any Turkish university or even in other world universities, at least at undergraduate level.

Sabancı University stands unique in Turkey in allowing students to declare their diploma areas at the end of their second year in an absolutely unconstrained manner – i.e. no program quotas, no performance requirements etc. The purpose of this liberal principle is to maximize student motivation and responsibility. In a patriarchally oriented and hierarchically organized educational system - and in general a society - this comes as a cultural shock to all the students. There is a faculty advising system that informs and helps students in choosing their diploma areas and that supports them in solving their academic and social problems. In addition to faculty tutoring and advising system there is a *Center for Individual and Academic Development* (**CIAD**) in which professional staff as well as bright junior and senior students perform tutoring activities to freshman and sophomore students.

Sabancı University is also unique in the country in its well-designed IT infrastructure. All undergraduate and graduate students are given a laptop computer for their use as soon as they enter the university. After two years all laptops are renewed through an agreement made with the company that leases the laptops. The university has a high bandwidth internal fiber network and external connectivity is one of the best in the country. There are nearly 9000 network entry points at a large number of classrooms, student dormitories and faculty housing, all information center (library) study desks, faculty and graduate student offices, all labs etc. Access to information is smooth and uninterrupted. Such an infrastructure helps students become computer literates at an early stage after they enter the university even before taking a single formal course in computer science.

Sabancı University is structured to make up for the gaps in the Turkish secondary education mentioned in the previous section. These are very briefly summarized below:

- **University courses.** These are mostly first year courses to make up for the lack of literacy both in sciences and mathematics and social sciences . All students are required to take these courses. The emphasis is more on concepts and less on background building and technicalities. For example there is a two semester freshman course *Science of Nature* integrating concepts in physics, chemistry and biology where, for example, in physics, rather than exhausting all topics three concepts : mathematical formalization, action at a distance and the universe of small particles are covered in the context of classical mechanics, electromagnetic theory and quantum theory respectively. *Humanity and Society* is an introductory anthropology-history course which presents to the students a well-designed set of topics rich and meaningful in intellectual contents and not overridden with indoctrination concerns. Taken together university courses expose students who aspire to become engineers or scientists to historical and social concepts to enlarge their vision of the world in their post-university lives as professionals and citizens. On the other hand it exposes students who want to study arts or human sciences to the concepts and culture of sciences without overburdening them with technicalities.
- **Faculty courses.** These are mostly second year courses offered by **FENS** and **FASS**. These courses are basic professional or background courses of the diploma areas. Faculty courses give the students a deeper understanding of a diploma area and in that sense can be used as instruments of window shopping in making their choices.
- **Independent team projects.**
    a) All students, either in their language preparatory year or first year are required to participate in a community activity for a total of 40 hours. For that purpose the university has established close links with NGOs such as Earthquake Relief, Human Rights, Amnesty International, Care for Street Children etc. both in the vicinity of Istanbul and in more remote and deprived parts of Turkey. This sharpens the students' socialization habits with a strong

component of commitment and responsibility.

b) All **FENS** students are required to take a team project course at the spring semester of their first or second year. The project topics are suggested mostly by the faculty members and sometimes by the students themselves.

c) At the end of their third year all **FENS** students are required to complete an 8-10 weeks of internship in an industry. The internship is also structured on a team project where a technical representative of the industry and a faculty member either jointly advise the project or at least maintain a reasonable amount of coordination. All internship projects are publicly presented in poster sessions within a specified week of the following semester.

d) Finally FENS students are required to take a two semester design and implementation course in their senior year. Since students have already acquired prior experience in independent project courses or activities as summarized above, our professional expectation from the design and project course is more ambitious. The outputs of these projects are desired to be at most one step away either from a commercializable or a precompetitive product or process of high calibre. The evidence so far neither confirms nor negates our ambition. More time and experience is needed for further structuring this course into a positive and fruitful experiment.

To summarize, independent team projects described above enrich the hands-on learning, communication, presentation and socialization abilities and skills of the students.

Sabancı University can be viewed as a managerially run university in the fashionable parlance of university management theories. At the topmost layer of management is the board of trustees that usually meet four times a year . The administration of the university has a dual structure. Non-academic administrative tasks are run by an administrative staff managed by the general secretary of the university. The administrative functions of the faculty members are reduced to purely academic matters such as tasks in committees for curriculum improvement, juries for graduate theses or undergraduate projects etc. The rector, as the highest administrative and academic officer of the university plays a key role in maintaining a healthy communication between the business or bureaucrat minded administrative staff and the academic community. There is a separate office directly responsible to the rector that manages all external relations such as funded projects, relations with other research institutions or commercial companies etc. Because of the widely differing cultures of managers and academicians the system requires good communication between the parties involved. It is a common hope that as the system evolves, institutional learning will gradually build a unique collective culture.

So far we have described features of the university related to education and administration. The research vision of the university is aptly summarized in the understanding stating that *the dissemination of the research results for the good of the society at large is a distinct mission of the university*.
In the context of **FENS** this translates itself as getting involved in activities like technology transfer to public or private companies, assuming a primary role in founding hi-tech start-up companies, actively participating in technoparks etc.

FENS research strategy is founded on three pillars. The first pillar is basic research, the output of which is scientific publications and practical know-how accumulated within the research labs. The second pillar is possibly commercializable research in knowledge intensive hi-tech areas. So far as the university mission goes this is the pillar of greatest strategic importance The third pillar is fund generating activities or projects. Such a project may have been originally initiated by a faculty member as an R&D activity and after reaching a saturation phase where things become routine the project can be continued by specially hired staff or university related companies to generate steady funds for the university. The most desirable R&D projects are those for which the three objectives above overlap. However, reality is not always that generous and maintaining a suitable balance between these activities is important.

The undergraduate and graduate programs as well as research interests in **FENS** constitute interwoven, future-looking and knowledge-intensive areas. There is a definite harmony between the choice of areas, research strategies and interdisciplinary concerns. Short term research concerns heavily lean on applications of information and communication technologies in all aspects of life whereas longer term research concern is that of *engineering in the small* in materials, biology, mechatronics, microelectronics and optics.

PRINCIPLES IN ACTION

In this section we summarize some of our observations and comments based on the past four years of experience.

An interesting example of unleashed student energy occured a year after the introduction of student team projects in Spring 2000. Motivated by this project course and through the efforts of the mechatronics faculty members a number of first and second year students decided to enter a national competition in robotics which was part of a world wide competition organized by Japan. As a result of hard and arduous work these students were able to win the national competition by eliminating groups of fourth year mechanical engineering students coming from two of the best rated and well established state universities. They then went to Tokyo and were able to end up within the first eight contestants out of approximately 25 nations and won a prize for that. This has set an example within the university making mechatronics a popular choice and further accelerating the competition between the seven programs for attracting the best students.

A program that has proved extremely popular is the community projects done in cooperation with the NGOs as described previously. A significant number of junior and senior students still maintain their ties with the NGOs with which they had first worked a number of years ago. Aside from having developed a sense of social responsibility and political maturity this activity has been the *first* occasion in which they improve their computer literacy by becoming fluent power point and excel users and by learning to make ample use of information resources of the library and the internet.

In a liberal environment where students were forced to make their personal choices and program their daily routines under academic pressures two problems became visible. These were time and stress management problems faced by the students. Special courses were organized by **CIAD** on both time and stress management which in time became popular and are still repeated every now and then.

On the research side there have also been spiriting developments. Sabancı University recently became a partner in a technopark company that is now actively launching training and recruiting activities for attracting progressive hi-tech companies. This technopark is placed within a privately funded industrial site about ten kilometers away from the campus. The expectation is that at some stage this technopark to become an outlet for our enterpreneural students and the creative technological research carried out in the university labs.

As an example for progress in commercializable research activities two short term projects have been completed for a multinational German company , one in computer vision applied to industrial production process and the other a control problem involving removal of a belt instability problem in a serial production system. Sabancı University has again set a unique example in successfully completing research projects for a reputable European company in a very *professional* manner.

Notwithstanding these positive moves and success stories there are also problems. In order to meet the challenges in education and research faced by **FENS,** high calibre students are needed. This however depends on the scholarship policy, which in turn depends on the business plan according to which the ratio of students with full scholarships will have to drop to less than 30% from the original 50%. This means that systematic and creative publicity and promotion campaigns of the university targeting high schools with highly rated students who can afford to pay tuition fees must be repeated intensively and frequently. Or other creative arrangements must be seeked for generating repayable loans for good students who cannot afford to pay.

Students usually respect the views of their peers and seldom trust advise coming from academic or administrative officials. This means that as the new culture starts settling in inter-student communication is the most effective means of proliferating and transforming the new mentality into a liberal academic tradition owned up by the students. This takes time and the university management must exhibit persistence and determination to guard the liberal environment within which students can freely express their views and practice their creative activities.

Another difficulty is to generate a common culture among faculty members whose origins constitute a heteregenous mix: either fresh PhDs mostly from US universities or engineers or scientists from other academic institutions, research institutions or industry. The correct balance between academic or scholarly activities and technologically creative activities that fit the **FENS** research strategy mentioned above requires an unorthodox academic performance system that must be designed and implemented in support of a common culture and understanding. We are at best halfway in our efforts in this direction.

CONCLUSIONS

As we approach the end of the first four year undergraduate program cycle this year, Sabancı University has already established a reputation for being one of the most innovative universities in the nation.

In the last fifty years two universities in Turkey have made history by setting examples to others. The first one was a milestone for moving the entire system to a US–like structure from the old Germanic model and normalized English as a universal language of communication. The second one was the first private university in Turkey that proved that by moving outside the boundaries of the state system one can build a world class institution measured by its scholarly activities. Sabancı University aspires to become a third such milestone through its impact on society by gearing its activities to transfering technological innovations into industry through its agents, namely its faculty and its graduates. This is why and how education meets research in the context of **FENS** of Sabancı University.

Sabancı University will perhaps resemble in time to one of the five enterpreneural European universities thematized in Burton Clark's celebrated book:

Creating Enterpreneural Universities : Organizational Pathways of Tranformation, Elsevier 1998.

Yet there are a few differences in the nature of innovations reported here. The innovations in Clark's examples stem from very creative managerial maneouvers in the context of highly rigid state university systems in four European countries. The managerial dynamism to transform the income base of universities by an order of magnitude by mobilizing the technological and educational capability of the faculty is no trivial matter. The same challenge is valid, important and indeed even a greater one for Sabancı University in view of the less developed technological base of existing industries in Turkey. On the other hand the strong student-centered and faculty-involved internal component of innovations mentioned here is non-existent in Clark's examples.

AN EMPIRICAL COMPARISON OF BACCALAUREATE PROGRAMS IN COMPUTING

Barry Lunt[1], Han Reichgelt[2], Tina Ashford[3], Andy Phelps[4], Erick Slazinski[5], Cheryl Willis[6]

Abstract *– When a new academic discipline emerges, it is often difficult to distinguish it from the disciplines closely related to it. Information Technology (IT) is just such an emerging discipline. This paper outlines the emergence of the Society for Information Technology Educatioin (SITE), a definition of IT curriculum, and positions IT relative to similar disciplines by empirically comparing it to programs such as Computer Science, Computer Engineering, Electrical Engineering, EET/ Telecommunications Engineering Technology, Information Science, and Management Information Systems, at a total of 12 institutions.*

Index Terms – academic disciplines, computing, curriculum, information technology,

INTRODUCTION

Recently, a number of Universities in the United States and elsewhere have started baccalaureate programs in Information Technology (IT). In addition to the universities with which the authors are affiliated, other institutions include Capella University, Illinois State University, Indiana University, Pennsylvania College of Technology, State University of New York at Morrisville, the University of Baltimore, and the University of South Alabama. Most of the institutions in question have added the baccalaureate degree in Information Technology to other computing-related baccalaureate degrees already in their portfolio, such as degrees in Computer and/or Electronic Engineering, Computer Science, Information Systems, Computer Information Systems, Management Information Systems, and so on.

While some (e.g., Denning, 2001) welcome this development, others are less accommodating and argue that there is nothing that would make a baccalaureate program in IT sufficiently distinct from a baccalaureate program in an existing computing discipline to warrant a separate degree program.

There are two popular methodologies that one can use to try to refute the proposition that there are no significant differences between a baccalaureate program in IT and other computing programs. The first one is to engage in a more philosophical debate about the nature of IT and to distinguish it theoretically from, say, Computer Science or Information Systems. While such debate is not without merit, the results are often inconclusive, and opinions that were closely held when entering such a debate are, in general, not likely to be modified.

In this paper, we therefore adopt a second methodology that one might use in support of a particular position, namely an empirical investigation. The aim of this paper is to provide an empirical comparison between the structure of IT programs and the structure of other computing programs in support of the position that IT programs have a character of their own and are distinct from other computing programs.

METHODOLOGY

The problem with any empirical comparison is of course the measure that one uses. In this particular instance, the question is specifically how to determine the structure of a degree program. Courses that were required in each of the degree programs were classified into one of 7 categories, namely

- Business related courses;
- Courses concentrating on interpersonal communication;
- Software related courses;
- Courses on networking, web-related technologies or databases;
- Electronics and signals;
- Hardware;
- Physics, mathematics or chemistry.

Absent from the above categories are general education courses that were taken by all students at that particular institution because they are not unique to a given major, and therefore do not help define differences between majors.

The reason for classifying courses in this way was not arbitrary. In December of 2001, 15 representatives from schools currently offering baccalaureate programs in IT attended the first Conference on Information Technology

[6] Cheryl Willis, Industrial Technology, 334 T2, University of Houston, Houston, TX, USA, clwillis@uh.edu

Curricula (CITC I) in Aspen Grove, Utah, to discuss a number of IT related issues. One of the topics for discussion was IT curricula and delegates at the conference engaged in an exercise to capture their views on what a core IT curriculum should contain. Each delegate was asked to write down ach topics that they felt were important in an IT curriculum on a separate piece of paper. Some 700 pieces of paper were collected, with some obviously mentioning the same topic.

The topics thus collected were then classified into a number of categories, and their frequencies noted. 28 categories emerged from this exercise, of which the most frequent were

- Networking;
- Interpersonal communication;
- Software;
- Web systems design;
- Databases;
- Business related issues (e.g., project management, e-business, organizational structure);
- Digital communications;
- Data security/privacy;
- Mathematics;
- Systems design;
- Hardware.

Further details can be found in Lunt et al (2002).

The first author used these topics as a starting point in a pilot study to analyze the various computing and related degrees offered at Brigham Young University (BYU), Utah. In addition to Information Technology, BYU-Utah offers baccalaureate degrees in Computer Engineering, Computer Science, Electrical Engineering, and Management Information Systems. It was on the basis of this pilot study that he combined several of the categories to arrive at the seven categories mentioned earlier, and used throughout this study.

The numbers used in the study represent unit courses, the equivalent of 3 semester credit hours. This was done to simplify understanding of the comparison. If a course was listed as 2 semester credit hours, it counted as .667 classes.

One further issue that needed to be resolved was the fact that many programs allow students options and the question was how to rate these options. The methodology that we used was simply to score each course by a ratio. Thus, if the student was required to choose 2 out of 5 courses, then each course was given a rating of .4 (2/5).

In addition to his or her own institution, each author also analyzed the programs offered at one other institution. The only requirement was that the institution in question should offer a baccalaureate program in IT. This led to programs at the following institutions being analyzed:

- Brigham Young University, Provo (BYU);
- Capella University (Capella);
- George Mason University (GMU);
- Georgia Southern University (GSU);
- Macon State College (MSC);
- Pennsylvania College of Technology (PCT);
- Purdue University (Purdue);
- Rochester Institute of Technology (RIT);
- University of Baltimore (U of B);
- University of Houston (U of H);
- University of South Alabama (U of SA).

RESULTS

The summary table of the results of this study are given in Table 1 below. The study covered seven main academic disciplines, shown in alphabetical order in Table 1. In some cases, the names of these disciplines were a combination of similar programs, as in the cases of Computer Eng/Eng Tech (a combination of programs in Computer Engineering and Computer Engineering Technology), EET/Telecomm ET (a combination of programs in Electronics Engineering Technology and Telecommunications Engineering Technology), and Mgmt Information Systems (a combination of programs in Information Systems and Management Information Systems). This was done only after it was evident from the data gathered that these programs were similar enough to be counted together; it is not suggested by this study that these programs are identical.

One of the first things a person will notice when looking at Part 2 of Table 1 is the large number of programs found under the discipline of Information Technology. This is due to two factors: 1) every institution included in this study had to have a program in IT, or it would not have been included; and 2) some of the institutions included have multiple specializations within their program of IT, and they were different enough that they were included separately. This gave a total of 22 IT programs in the study. This was followed by 8 programs in Computer Science, 8 in Management Information Systems, 5 in Computer Eng/Eng Tech, 2 in Electrical Engineering, 2 in EET/Telecomm ET, and one in Information Science.

The number of courses required for the programs included in this study ranged from a high of 35 (Information Technology at Capella) to a low of 15 (Computer Engineering at GMU), with the average being just under 26 courses. The seven program areas had averages ranging from a high of 29.8 courses for EET/Telecomm ET to a low of 23.25 for Computer Science.

COMPARISON

It can be seen from the data in Table 1 that there is a great degree of variation in programs between institutions, even in programs as well-established as Computer Science. However, when one looks at the trends of the averages, the respective disciplines become very distinct. This is perhaps best shown in Figure 1, which is a graph of the percentage of classes required in each sub-area. For example, Figure 1 readily shows where the emphasis lies for programs in MIS: about 58% of all their required classes are in Business, with the other 42% being made up of Networking, Web & Databases (18%), Software (11%), Interpersonal Communications (6%), and Physics, Math & Chemistry (6%). There is essentially no required coursework in Hardware or Electronics & Signals.

This can be contrasted with programs in Computer Science, where the main components are Software (39%), Physics, Math & Chemistry (30%), Networking, Web & Databases (10%), Hardware (8%), Interpersonal Communications (4%) and a bit of Business (3%). This comparative view of the courses required in each topic area for each of the programs is best seen in Figures 2-7, one for each of the respective academic programs.

A comparison between the topics areas required for each program is the focus of this paper. Figures 2-8 show the relative ranks between the topic areas for each of the programs included in this study.

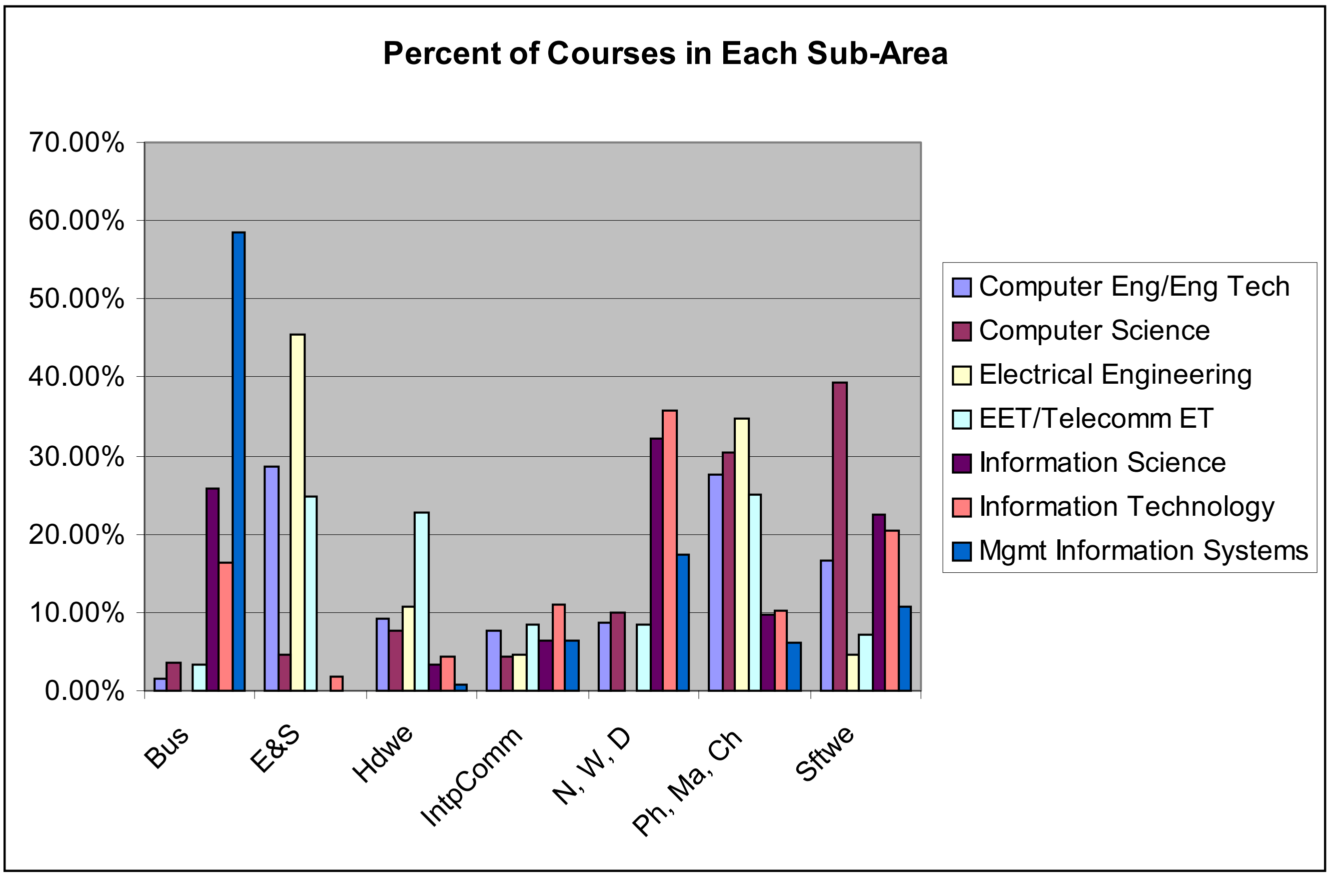

FIGURE 1

NUMBER OF COURSES REQUIRED BY EACH PROGRAM IN EACH SUB-AREA

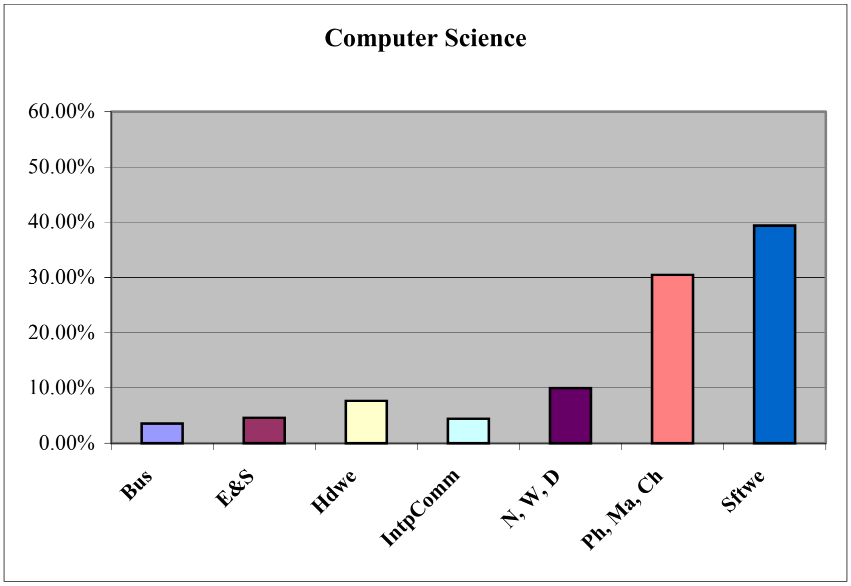

Figure 3
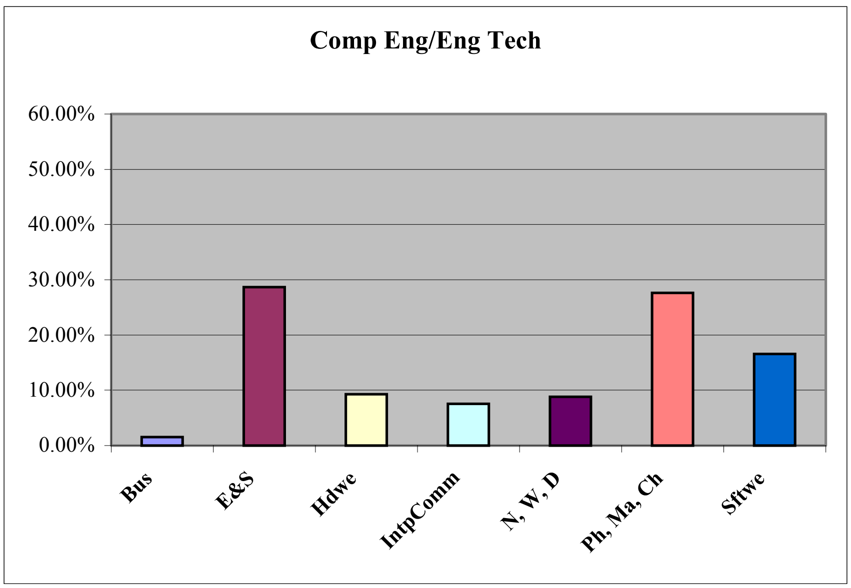
TOPIC AREAS BY RANK FOR PROGRAMS IN COMPUTER SCIENCE.



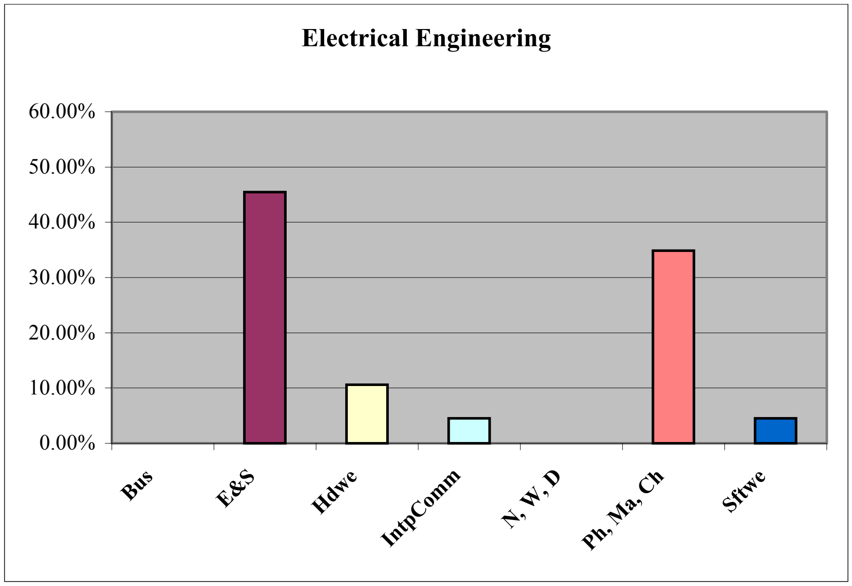


Figure 4

TOPIC AREAS BY RANK FOR PROGRAMS IN ELECTRICAL ENGINEERING.

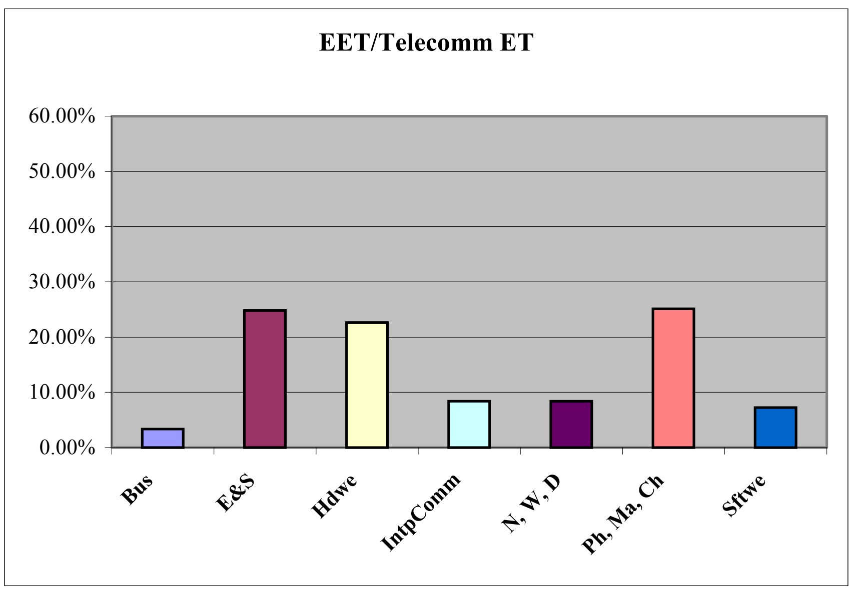

Figure 5

TOPIC AREAS BY RANK FOR PROGRAMS IN ELECTRONICS ENGINEERING TECHNOLOGY AND TELECOMMUNICATIONS ENG. TECH

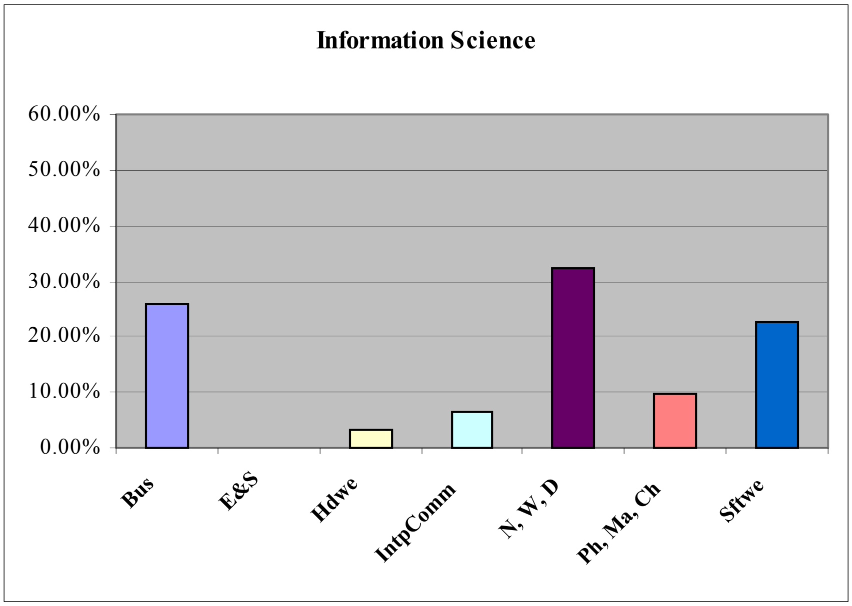

Figure 6
TOPIC AREAS BY RANK FOR PROGRAMS IN INFORMATION SYSTEMS

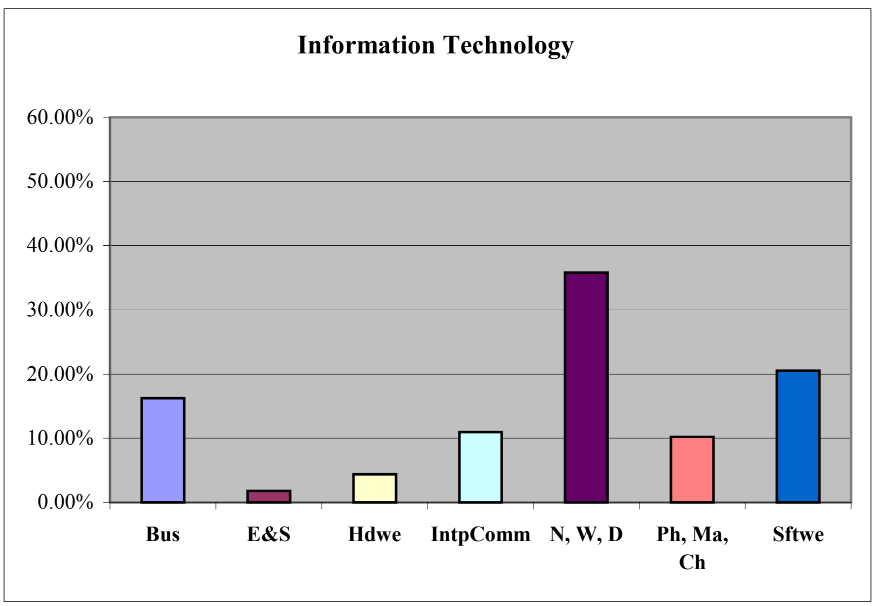

Figure 7
TOPIC AREAS BY RANK FOR PROGRAMS IN INFORMATION TECHNOLOGY.

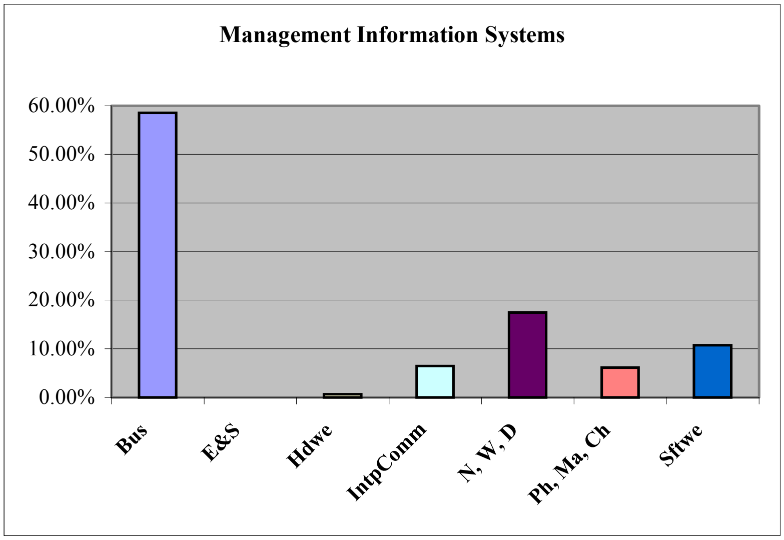

Figure 8
TOPIC AREAS BY RANK FOR PROGRAMS IN MANAGEMENT INFORMATION SYSTEMS.

It is typical for any program to have two or three strength areas, followed by appropriate support topic areas. It is evident from Figures 6 and 7 that the strength areas for programs in Information Systems and Information Technology are 1) Networking, Web & Databases; 2) Software; and 3) Business, with only a slight difference in the #2 and #3 areas. The strength areas for programs in Computer Engineering or Computer Engineering Technology are 1) Electronics & Signals and 2) Physics, Math & Chemistry, which shows their strong emphasis on electronics and basic engineering principles. A similar emphasis is seen in programs in Electrical Engineering, where the strength areas are the same, but make up a much greater part of the curriculum. Similarly, the strength areas in programs in Electronics Engineering Technology or Telecommunications Engineering Technology are 1) Physics, Math & Chemistry; 2) Electronics & Signals; and 3) Hardware, making up a combined 72% of the curriculum.

As one would expect, the strength areas of programs in Computer Science are 1) Software and 2) Physics, Math & Chemistry, with an emphasis on the Math. And also, as implied by the name, the focus of programs in Management Information Systems is Business, making up over 50% of the curriculum,

with a secondary emphasis in Networking, Web & Databases making up about 18% of the curriculum.

CONCLUSION

It is the hope of the authors of this study that the preceding information, especially the tables and graphs, will be helpful in two main endeavors: clarifying the differences and unique characteristics of existing programs in Information Technology, and assisting in academic advisement in the field of computing. When any new program emerges from closely related programs, it is often difficult for those in the closely related programs to clearly distinguish the differences between these programs, and to understand the unique focus of the new program. This paper has presented information which should significantly promulgate a better understanding.

Many are the students who are interested in the broad area of computers, but a large number of these students are quite unaware of the different programs that deal with computing and their respective emphases. This paper should be very helpful in clarifying this situation as well. For example, a student interested primarily in the Networking, Web and Databases part of computing would be well advised to go into either Information Systems or Information Technology. Those interested primarily in the software should go into Computer Science, while those whose interests lie most strongly in computer hardware should be advised into programs in Computer Engineering, Computer Engineering Technology, Electronics Engineering Technology, or Telecommunications Engineering Technology. Students who love the business applications of computers should be advised into Management Information Systems.

COLLABORATIVE LEARNING IN INTERDISCIPLINARY AND INTERCULTURAL TEAMS

Arvid Andersen

Abstract*— *Many observers consider that Engineering courses in general should turn out graduates who

- *Are proficient with open-ended problem solving*
- *Are familiar with multidisciplinary problems*
- *Posses teamwork skills*
- *Posses appropriate entrepreneurial and social skills*
- *Are able to plan and run a project effectively*
- *Have the ability to communicate efficiently*
- *Are proficient with computer systems and applications*

Let us admit that the Paradigm has changed and adjust accordingly. Various avenues of teaching, learning and assessment, such as those described in this paper, are required to develop soft and hard skills needed. The educational concept described i.e. simultaneous cross-cultural and interdisciplinary teamwork influences the individual personal attributes. Through project organized teaching/learning mental agility as well as inner resilience are influenced and strengthened. After completing this semester course students posses a blend of personal attributes and soft and practical entrepreneurial skills. Further it has been shown that students learn good judgement tinged with sagacity. In using our modern computer facilities students become rather proficient in management of engineering projects and applications.

Index Terms—*Avenues of learning, diversity, international teamwork, project performance, theory and practice*

INTRODUCTION

Global awareness is of paramount importance. International collaboration and cooperation are developing very fast and require knowledge and understanding of cross-cultural business behaviour. In order to deal and compete on the global market, we must make sure that the qualifications of our engineering graduates are appropriate. Future researchers predict, that work in future life will merge with leisure time and family life making things more blurred. It is expected that engineers in the future will be given a special task rather than being employed in a company from nine to five. In Denmark there is already a tendency to employ people on short-term contracts buying competence and expertise rather than employing people, as we know it to day. This requires a solid basic engineering knowledge combined with the ability to tackle problems alone and solve them in cooperation and collaboration with people across disciplines and cultures. Understanding of a broader area of disciplines such as economics, marketing, environmental subjects, management of engineering projects and a solid training in teamwork are required. Both Society in general and engineering have become increasingly more technologically advanced. This produces a demand for many new skills that our graduates must posses. The new skills base is no longer just technological. There is now an increasing demand for our graduates to be proficient with open-ended problem solving and with computer systems and applications. In addition, to have the ability to plan, navigate and manage complex engineering projects, work systematically and be able to work in multidisciplinary teams with international participation where the common language is English.

A major supporting activity in engineering courses in Denmark is the use of an extended project based activity. This is to day considered to be such an important part of the general teaching technique of learning that it is being extensively employed. This teaching and learning technique is based on the dual concepts often referred to as Collaborative learning and Scaffold Knowledge Integration.

COURSE DELIVERY

As described in the Scaffold Knowledge Integration framework, autonomous learning is facilitated on the course by having students work in project groups to allow them to:

1. Serve as social supports for each other
2. Share design ideas and provide feedback
3. Provide critical assessment of the ideas of others
4. Discuss, negotiate, debate and compare

The assignments undertaken are designed to make students listen actively to each other, to make mistakes, to argue, to discuss and to explain their ideas to other students, to members of the academic staff and to experts from industry.

FINDINGS

Interdisciplinary working combined with the participant's diversity in cultures needs careful scrutiny by lecturers, supervisors, mentors and participants. A number of key issues are the differences between the deal focused and the relation focused way of conducting meeting and negotiating between different suggestions. The level of informality in some cultures such as Denmark and the UK and the formality-structured relation ships in several mainland Europe cultures can cause strained relationships. Sensitivity to status differences and the

Arvid Andersen, Professor, director of European Project Semester (EPS), dept. of Export Engineering, Engineering College of Copenhagen (IHK), Denmark, jar@ihk.dk

rigid hierarchies frequently displayed in a number of Universities can also provide initial uncertainty in students.

DIVERSITY

To appreciate diversity and take advantage of it in collaborative learning is essential. However, to do so we need to be aware that each individual has a perception and understanding of the way things are or should be. This situation is strongly accentuated when dealing with students mixed in multi-cultural and multidisciplinary teams. All involved i.e. students, supervisors or staff should know that diversity in cultures means different mind-sets and therefore many individual paradigms. Normally we do not question such differences in our individual perception of life. However, this is exactly what we need to do when dealing with mixed teams of different disciplines and cultural backgrounds. Each team is typically a mix of three different cultures and four to six different disciplines working as an integrated engineering group. All projects are real projects done in cooperation with Danish or foreign industry. Language of communication is of course English.

STUDY DISCIPLINES INVOLVED

The basic structures of the programme of study are designed to give participants an overview of the diverse fields of engineering business and technology and to break down barriers between disciplines and promote a common approach. This course has shown to familiarise the students with the practice of engineering analysis, design and problem solving. This is achieved by providing a set of project-based activities designed to simulate the real world engineering practice. In this case practice relates to the skills required to achieve a successful project. At the start of the project student teams struggle with their project/problem formulation and planning trying to allocate activities related to the individual fields of study involved. As the project progresses the differences between each of the technical disciplines begins to disappear, and the class begins to extract engineering and technical skills that are consistent across disciplines involved. This is where student starts to recognise the interdisciplinary nature of the operation and see the possible solutions to the various parts of their project.

PROJECT PERFORMANCE, LIMITATIONS AND DIFFICULTIES

It is well known that it is necessary to have a certain amount of knowledge and insight to be able to resolve problems and to be creative. To accommodate a wide range of student disciplines requires a great number of broadly based projects within engineering, business and technology. To accommodate different cultures and disciplines in the same team requires certain skills, patience, time and understanding. It further requires consideration and courage to resolve cognitive, political and social problems as they occur. Although students technical background/knowledge is similar it can be very difficult to communicate. Also conflicts in student's individual aims and ambitions must be published and discussed among team members to promote the project performance. Further it is important to tell each other what is required of the home university. In case of trouble a facilitator, usually a supervisor or a qualified tutor is consulted.

AVENUES OF LEARNING

Following is a list of avenues of teaching and learning applied:
Project Organized Teaching i.e. problem oriented or discipline oriented.
Self study
Independent and autonomous learning
Traditional class teaching
Working together where students share and distribute the responsibility of learning
Helping each other
Collaborative learning
Supervisor consultation
Practice of making things (prototyping)
IT, Blackboard, web learn
Ad hoc teaching according to immediate need
Group meetings
Tutorial sessions with Oral Presentation exercises and written feedback from the audience

METHODS AND TECHNIQUES USED

A mix of different situations and events deliberately designed reflects the avenues of learning practised on this semester. These events enable students to present, discuss and defend their professional work and discuss other matters of concern such as communication problems, cognitive and political problems in their group. Teaching and learning methods such as autonomous learning, tutorial discussion sessions where oral presentations are performed and discussed, group meetings where teams present, defend and discuss their work with each other, weekly meeting with supervisor, here students plan, organise and prepare the meeting, they work out the agenda for the meeting, they take minutes and they take turns in chairing the meeting. As we express it: We pay attention to the 3P´s as we have defined it: The PRODUCT i.e. the documentation set, the PROCESS performed i.e. the teamwork and the PEOPLE involved. Also use of our web-based blackboard system should be mentioned which is used as a distant learning tool. It is also used as a forum for discussion. Here the professor can work on distance and participate in discussion with students.
Each team of international students is involved in defining, systematizing, planning and navigation of their project. Two supervisors, a commercial and a technical, are allocated to each team. On compulsory weekly meetings things of concern such as project development, teamwork problems and

communication difficulties and if needed cognitive and political problems are discussed. From those meetings students learn good meeting techniques and disciplined behaviour. Further they learn to work out a good agenda for the meeting and to write a good minute of the meeting. Abilities such as awareness, self- confidence, responsibility and communication in English are improved through those activities. Also the ability to listen actively, discuss and negotiate solutions in place is developed. Company advisors do join the weekly meetings if their busy timetable allows. All team supervisors meet regularly to discuss matters of concern.

THEORY AND PRACTICE

It is essential that University reach out to Industry to establish a good relationship. It is crucial to get industry involved and committed in education of engineers. The Engineering College of Copenhagen is an undergraduate institution. The study is vocational i.e. a mix of theory and internship in industry. Students enrolled here find this combination very useful and relevant and a real eye-opener to many students. To illustrate their concern for a proper mix of theory and practice the following statement, expressed by a by a student representative at a graduation ceremony, will serve. Quote: " Theory is when you know everything but nothing works. Practice is when everything works but nobody knows why. Therefore keep calm and combine your knowledge or else you might find out that: Nothing works and nobody knows why" Unquote.

ASSESSMENT

Interim report, self and peer assessment, project report and oral exam. Assessment procedure for the team-based project:
1. Oral presentation of the written report
2. Discussion of professional, technical and specific content of the report
3. Discussion of the precise communication value of the written report
4. Evaluation of the project-process

MOBILITY OF STUDENTS ACROSS BOARDERS

Since the inception of the European Union student funding programmes such as Socrates/Erasmus, Leonardo, Tempus and Comett students have been increasingly encouraged to move part of their study to a foreign University. The number of students and the range of countries annually involved in international exchange of students have increased dramatically. The EORUPEAN PROJECT SEMESTER (EPS) programme reflects this general trend. From six students in 1995 coming from three countries to 80 international students per year coming from 14 different countries in 2002.

STUDENT STATEMENT

Andrew Perez, a participant in 2001, graduate from University of Notre Dame 1999 with a degree in Mechanical Engineering says about this international teamwork semester: "This semester programme is essentially a semester devoted to a final design project, which is provided and partially supervised by Danish companies. Just like at Notre Dame it entails a team based approach, a lengthy final paper and also a final project presentation. The differences, however, is that my team-mates were from different countries. My team consisted of three women from Spain, The Netherlands and Lithuania. Likewise, the six other groups comprised of multinational teams presenting most of the countries in Europe. Within my group there were two engineers and two business majors, which was tailored perfectly to our project.

Let me start by saying that I cherish this experience as much as I do my four years at Notre Dame. I have learned more about world, the life and myself in the last five month than I have in my previous 24 years of living. I came to the programme believing that with my credentials and experience, I would be able to easily succeed in this setting; I have never been so wrong I my life. My error was that while I have experience working with Americans of various ages and egos, we are all American and therefore predominantly of the same mindset. When I started working within a multi-national team, I found myself having to reinvent my work habits, my communication skills and my choice of words. It was a huge and complete paradigm shift.

Personally, I am forever changed because of this program. I can assure you that this sentiment was also shared by the other American attending and by every single other participant. I am not sure how this program would fit into Notre Dame's strict four-year curriculum, but if you are serious about improving the quality of the degree, then look no further than across the Atlantic to a small country in the north".

CONSTRUINDO UM PORTAL PARA CRIANÇAS COM CRIANÇAS: UMA ABORDAGEM PARTICIPATIVA AO DESIGN

Amanda Meincke Melo[1] *and M. Cecília C. Baranauskas*[2]

Abstract *— Sistemas de Informação na Internet ampliam a possibilidade de construção de conhecimento através do acesso à informação e da interação entre as pessoas. Enquanto educadores reconhecem a influência dessa mídia na educação de jovens e crianças, ainda são necessários muitos esforços com o objetivo de oferecer ambientes na Internet que atendam às especificidades das crianças e façam sentido para elas. A literatura de Interação Humano-Computador tem mostrado a importância de trazer o usuário para o processo de design de software e várias propostas metodológicas têm sido discutidas. Uma vez que reconhecemos a relevância de trazer as crianças para o processo de design, nossa proposta inclui atividades planejadas com o objetivo de ter crianças como co-autoras de um site na Internet. As crianças que participaram dessas atividades apontaram que desejam um espaço para se divertir, aprender e trocar experiências. Suas idéias para o espaço infantil na Internet – sugestões sobre conteúdos, atividades, suas formas de apresentação e acesso – foram utilizadas para informar a modelagem do sistema. Esse artigo tem como objetivo discutir o processo de design de um site infantil com a participação de crianças.*

Palavras-chave — Internet, crianças, design participativo, sistemas de informação.

INTRODUÇÃO

Sistemas de informação na Internet ampliam as possibilidades de construção de conhecimento através do acesso à informação e a mecanismos de interação entre as pessoas.

Enquanto o uso desta mídia pelas crianças tem crescido cada vez mais e sua influência na aprendizagem tem sido reconhecida por educadores, ainda são necessários muitos esforços com o objetivo de oferecer ambientes na Internet que atendam às especificidades das crianças e façam sentido para elas [14, 2].

Ainda hoje, a participação das crianças na mídia está bastante restrita ao acesso a informações, sendo poucas as iniciativas que garantem às crianças o direito à liberdade de expressão e definição dos conteúdos e suas formas de apresentação [8].

A importância de trazer o usuário da tecnologia para o processo de design de *software* tem sido largamente reconhecida. Áreas do conhecimento como a Engenharia de *Software*, Sistemas de Informação e principalmente a área de Interação Humano-Computador (IHC) mostram diferentes maneiras de envolver o usuário no processo de criação de artefatos computacionais: em atividades de avaliação e testes [17]; em observações e/ou entrevistas [5]; como parceiros nas atividades de design [20]. Esse envolvimento não tem ocorrido da mesma maneira quando o usuário é uma criança. No máximo as crianças são chamadas a participar de atividades de teste de novos produtos, em geral em cenário escolar.

Trabalhos de pesquisa como os de Druin [10], Barcellos e Baranauskas [3], Barcellos [4], Baranauskas e Barcellos [1] mostram que, assim como o adulto, a criança como uma categoria de usuário, tem muito a contribuir no processo de design de tecnologia para seu uso. Como bem coloca Druin [9], as crianças são capazes de falar sobre o que gostam ou não gostam, têm curiosidades e necessidades que não são as mesmas dos *designers* de *software*, de seus pais ou professores.

Este trabalho tem como objetivos apresentar a abordagem participativa utilizada no design do portal Caleidoscópio Júnior e discutir como a significação de crianças para o espaço infantil na Internet, a partir da sua atuação com elementos de design, foi carregada para o processo de desenvolvimento do portal.

O artigo está organizado da seguinte forma: a Seção 2 apresenta o referencial teórico para o trabalho; a Seção 3 apresenta as atividades realizadas com crianças para envolvê-las no design do portal Caleidoscópio Júnior e seus principais resultados; a Seção 4 discute como esses resultados derivaram no sistema e apresenta alguns aspectos da implementação do portal; a Seção 5 conclui.

DESIGN PARTICIPATIVO E O CONTEXTO DA CRIANÇA

O Design Participativo (DP) [16, 6, 11] teve início na Escandinávia na década de 70, com suas bases fundamentadas no princípio da democracia no ambiente de trabalho. Nesta abordagem os sistemas computacionais são "desenhados" pelos *designers* e usuários em conjunto, contrapondo a abordagem tradicional ao desenvolvimento de sistemas computacionais, onde muitas vezes os interesses dos usuários do sistema não são considerados, ou não são

[1] Amanda Meincke Melo, Instituto de Computação, Universidade Estadual de Campinas, Cx. P.: 6176, 13.083-970, Campinas, SP, Brazil, amanda.melo@ic.unicamp.br
[2] Maria Cecília Calani Baranauskas, Instituto de Computação, Universidade Estadual de Campinas, Cx. P.: 6176, 13.083-970, Campinas, SP, Brazil, cecilia@ic.unicamp.br

captados de maneira satisfatória. Na abordagem tradicional, em geral, prevalece somente o interesse de quem contrata o sistema e a vontade dos próprios *designers* do sistema.

Outro aspecto a ser destacado no DP é a possibilidade de melhorias no próprio processo de design. A colaboração dos usuários no processo de desenvolvimento provê subsídios e o *feedback* adequado para os *designers*. Além disso, o DP surge como uma abordagem capaz de aprimorar a qualidade de design e do sistema resultante, através da melhor compreensão da atividade do usuário e da combinação das experiências dos diversos participantes do processo de design [7].

Em adição aos aspectos políticos conseqüentes do design participativo em sua versão escandinava original, a pesquisa em DP ganhou novos contextos socioculturais em outras partes do mundo e em geral visa desenvolver práticas que promovam uma cooperação produtiva entre *designers* e usuários.

Druin [10] observa que essa abordagem ao design, que tenta capturar a complexidade e aspectos do contexto do trabalhador pela sua própria perspectiva, poderia ser útil também para capturar aspectos do contexto da criança. A criança como parceira de *designers* e educadores no design de tecnologia tem sido apresentada nos trabalhos pioneiros de Druin [9], que propõe como equipe de design um grupo que a autora denomina *intergenerational*. Essa equipe inclui membros de diversas idades, disciplinas e experiências, sendo que algumas crianças têm feito parte da equipe juntamente com educadores, cientistas da computação e artistas.

Enquanto reconhecemos a importância de trazer a criança ao processo de design, estamos igualmente interessadas em entender o processo de significação da criança a partir da atuação delas com os elementos de design e refletir no sistema, através de sua interface, esse entendimento. Em função do estágio de desenvolvimento cognitivo em que se encontra, a criança nem sempre consegue expressar, da mesma maneira que o adulto, idéias abstratas [19]. Assim, o *designer* deve interpretar as ações da criança com os objetos concretos e simbólicos utilizados e gerados nas atividades participativas.

Participação e Significação como Base do Processo de Design

O entendimento do contexto de significação, capturado em atividades participativas, deve ser representado de maneira a informar a modelagem do sistema. Argumentamos que métodos da Semiótica Organizacional (SO), em especial a Análise Semântica, podem facilitar essa transição do que resulta de atividades participativas para o design do sistema. Dessa maneira o significado é construído como resultado da cooperação entre os *designers* e as crianças, usuários prospectivos da tecnologia.

A Semiótica Organizacional é uma disciplina que explora o uso de signos e seu efeito em práticas sociais. Baseada nas escolas de Peirce [18] e Morris [15], a SO propõe um conjunto de métodos para o design de Sistemas de Informação. Organização é entendida num sentido amplo como um grupo de pessoas, uma sociedade, uma cultura, que não somente compartilham regras de linguagem, costumes e hábitos, mas também participam da construção social dessas regras. A Análise Semântica é um método utilizado para produzir modelos semânticos ou diagramas de ontologia do domínio do problema. A Análise Semântica apoia-se em dois conceitos principais: agente e *affordance*. Agentes possuem *affordances* manifestadas por padrões de comportamento, e, ao mesmo tempo estão sujeitos a *affordances* dos objetos e agentes com os quais interagem.

O conceito de *affordance* foi proposto por Gibson [12] e utilizado pelos estudiosos da abordagem ecológica à percepção visual, para designar o comportamento de um organismo possibilitado por alguma estrutura combinada do organismo e seu ambiente. Por exemplo, se uma superfície terrestre é horizontal, plana, rígida, relativa a um determinado animal, então essa superfície "*affords*" suporte. Da mesma maneira, artefatos da nossa cultura *afford* um tipo de utilização. O formato da maçaneta da porta *affords* o tipo de movimento necessário para abrir a porta. O que percebemos quando olhamos para objetos são suas *affordances*, não suas qualidades. *Affordances* não são propriedades físicas ou fenomenológicas; são propriedades tomadas relativas a um observador [12: 143].

Conforme apresenta Gibson, entretanto, o conjunto mais elaborado de *affordances* do ambiente é fornecido pelas outras pessoas que interagem com o observador, umas com as outras e com os objetos do mundo. Comportamento *affords* comportamento.

A definição dos conceitos de agente e *affordance* em SO é sensível ao contexto; um agente pode ser simplesmente uma pessoa e ser ontologicamente dependente de algum agente mais complexo, por exemplo, a sociedade. Nesse caso o agente pessoa é, ele próprio, uma *affordance* de sociedade [13].

O método de Análise Semântica possibilita modelar um sistema computacional com o foco em agentes e *affordances*. O método pode ser sumarizado em quatro fases principais: definição do problema, geração de *affordances* candidatas, agrupamento de *affordances* e criação do diagrama ontológico.

A definição do problema é a primeira fase da Análise Semântica, onde o problema a ser modelado é introduzido basicamente através de um enunciado. Esse enunciado pode servir como uma fonte inicial de agentes e *affordances*. Mas em geral o enunciado do problema é muito vago, e atividades de design participativo podem colaborar na descoberta das atribuições do sistema e de seus usuários. Na fase de geração de *affordances*, o enunciado do problema é investigado e toda a documentação que colabora para a definição do problema, na busca de unidades semânticas que podem indicar agentes, *affordances* e suas relações. O agrupamento de *affordances* e o diagrama de ontologias construído pelo *designer* como resultado de seu entendimento da significação, por sua vez, podem realimentar novas práticas participativas e refinar esse processo de entendimento do problema e significação dos participantes a partir dos elementos de design. A Figura 1, a seguir, ilustra a abordagem proposta, envolvendo atividades participativas de design e Análise Semântica.

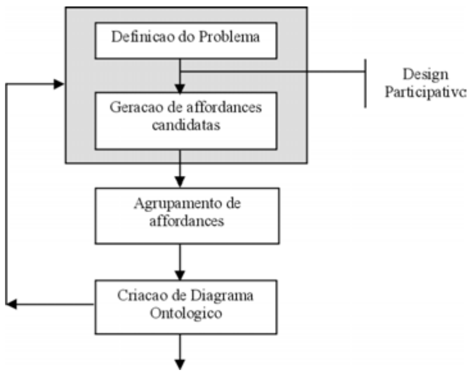

FIGURA. 1
DESIGN PARTICIPATIVO COMBINADO À ANÁLISE SEMÂNTICA.

DESIGN COM PARTICIPAÇÃO DE CRIANÇAS: UM ESTUDO DE CASO

Para participar do processo de design do portal Caleidoscópio Júnior, dez crianças entre 6 e 10 anos – meninos e meninas com diferentes níveis de acesso à tecnologia – foram convidadas a atuar em uma diversidade de atividades. O planejamento dessas atividades foi realizado por pesquisadores das áreas de educação, computação e IHC.

Os encontros com as crianças ocorreram durante 4 sessões de 2 horas cada, nos meses de outubro e novembro de 2001, no NIED/UNICAMP. Para registrá-los, foram utilizadas máquinas fotográficas, câmeras de vídeo e gravadores de som.

As crianças foram envolvidas em várias atividades, incluindo criação de protótipos do portal Caleidoscópio Júnior, exploração de uma ferramenta de comunicação para crianças na Internet, exploração de *sites* infantis e conversas que colaboraram para a troca de idéias sobre o espaço infantil na Internet.

Pela criação de protótipos, ilustrada na Figura 2, as crianças puderam expressar sua compreensão sobre a Internet, as atividades que gostariam de realizar em um espaço infantil na rede mundial de computadores, bem como os conteúdos desse espaço, sua forma de apresentação e acesso.

FIGURA. 2
PARTICIPAÇÃO ATRAVÉS DA PROTOTIPAGEM.

Na atividade que promovia conversas entre as crianças via Internet, o Papo-Mania – desenvolvido para o público infantil no contexto da educação inclusiva [3] – foi utilizado como ferramenta de bate-papo. Por meio da conversa estabelecida através do Papo Mania, as crianças puderam vivenciar uma das formas de interação e comunicação oferecidas pela rede mundial de computadores. Da atuação com a ferramenta e dos diálogos mantidos entre os participantes emergiram sugestões de modificações e incorporações de opções à interface da mesma.

Durante a navegação em *sites* infantis, as crianças mostraram algumas atividades de maior aceitação, suas expectativas em relação a esses espaços, os problemas relacionados aos conteúdos e às formas de apresentação dos mesmos e questões de segurança dos *sites* visitados.

As trocas de idéias sobre o espaço infantil na Internet ocorreram em diversos momentos e ofereceram indícios aos *designers* sobre o que havia sido representado pelas crianças nos protótipos do portal, além de complementarem as observações realizadas por eles durante a navegação nos *sites* infantis.

Pela participação nas atividades de design, as crianças mostraram que elas querem um espaço na Web para se divertir, aprender e trocar idéias com outras crianças, inclusive, de outros países. Sugestões de conteúdo, estrutura e atividades emergiram durante essas atividades e foram utilizadas para informar a modelagem do sistema.

Entre os conteúdos que elas querem acessar estão incluídas informações de como montar um caleidoscópio, sobre quem fez o *site*, sobre como o *site* foi inventado, informações sobre cinema, sobre plantas e links para outros *sites*.

Através dos protótipos, as crianças sugeriram diferentes estruturas de navegação para o portal. Entre as estruturas sugeridas – amparadas pelas metáforas de livro virtual, canais de televisão e mesa de trabalho, por exemplo [14, 2]–, as que fazem uso de menus laterais parecem ser mais fáceis de navegar, conforme apreendido da navegação em portais infantis.

As atividades que elas querem realizar no espaço infantil na Internet incluem trocar idéias com outras crianças sobre os mais variados assuntos – jogos, cinema, trabalhos escolares, entre outros –, jogar – jogos de tabuleiro, de estratégia e outros jogos –, fazer pesquisa escolar, desenhar e fazer agenda.

As crianças utilizaram cores, brilhos e elementos de interface comuns em ambientes computacionais como menus, caixas de seleção, botões (voltar, avançar, sair), ícones e textos para compor a interface do portal, indicando que já possuíam alguma familiaridade com o computador/Internet. Ao conversarem sobre as idéias que elas têm de *site* infantil, acrescentaram que alguns elementos são dinâmicos e interativos.

O DESIGN DO CALEIDOSCÓPIO JÚNIOR

Além de contribuírem para a definição da interface, os resultados das atividades participativas geraram os elementos semânticos básicos que compõem o portal e definem seu contexto de uso: agentes e *affordances*. Tais elementos foram, então, representados em diagramas de ontologias, conforme proposto na Figura 1. Os diagramas de ontologias representam, portanto, o entendimento e a expressão do *designer* para espaço infantil na Internet, a partir de sua interpretação da significação da criança para os elementos de design do portal. A Figura 3, a seguir, ilustra um dos diagramas de um conjunto que, combinados, compõem o projeto do portal como um todo.

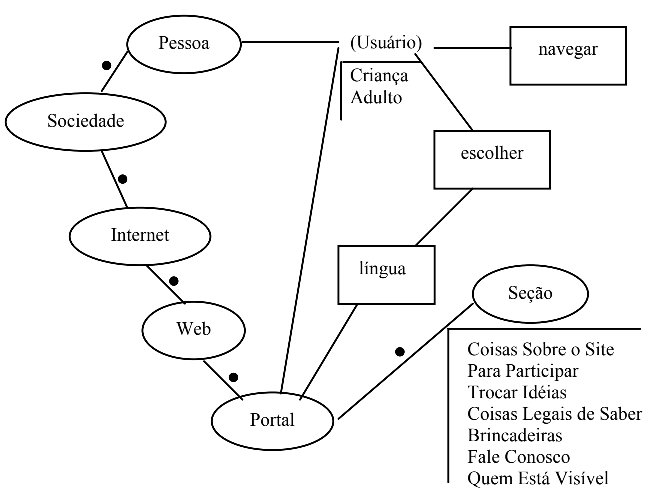

FIGURA. 3
UM DIAGRAMA DE ONTOLOGIAS: VISÃO PARCIAL DO PORTAL.

No diagrama de ontologias da Figura 3, existe um agente raiz: a sociedade, onde os significados sobre as ações das crianças na Internet são compartilhados de forma coletiva. A relação ontológica entre agentes e *affordances* é representada da esquerda para a direita. Por exemplo, a *affordance* "escolher" depende da existência de um "Usuário" – papel de "Pessoa" no "Portal" – e da *affordance* "língua", que depende da existência do agente "Portal". O diagrama também apresenta as "Seções" principais do "Portal", que agrupam os conteúdos do *site* e as atividades que as crianças querem realizar.

Os diagramas de ontologias, que descrevem o contexto do sistema de informação, serviram como fonte para a modelagem da base de dados do portal, juntamente com os materiais gerados durante as atividades de design com as crianças. Por exemplo, a idéia de que o portal fosse acessível para crianças de outros países – internacionalização do *site* – apareceu durante as atividades de *design* participativo e foi contemplada no diagrama de ontologias, sendo carregada para a modelagem da base de dados do portal.

A Figura 4, abaixo, mostra como os resultados das atividades com as crianças e os diagramas de ontologias derivaram no sistema.

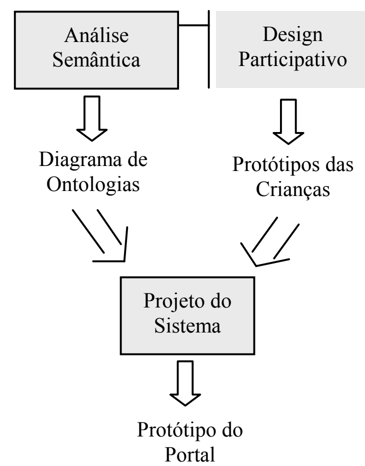

FIGURA. 4
DO REFERENCIAL TEÓRICO AO PROTÓTIPO.

Aspectos de Implementação

Entre as tecnologias utilizadas para implementação do portal estão HTML, CSS, JavaScript, MySQL e PHP.

A linguagem HTML, interpretada pelos navegadores Web, é utilizada para descrever a interface do portal Caleidoscópio Júnior. As folhas de estilo (CSS) permitem especificar a apresentação das páginas HTML – cor de fundo, formatação da fonte, estilo de bordas, etc –, independente de seu conteúdo. A linguagem JavaScript é utilizada para responder a algum evento no navegador. O MySQL é o servidor de banco de dados utilizado, enquanto que PHP é a linguagem de programação empregada para implementação da aplicação interpretada no servidor Web.

O uso dessas tecnologias permite a programação de interfaces customizáveis e de fácil manutenção. Um exemplo de customização da interface Caleidoscópio Júnior se refere à possibilidade de escolha de diferentes estilos de apresentação do conteúdo do portal pelo usuário. A Figura 5, a seguir, apresenta a página inicial do Portal Caleidoscópio

Júnior e destaca alguns de seus estilos de apresentação, que podem ser selecionados.

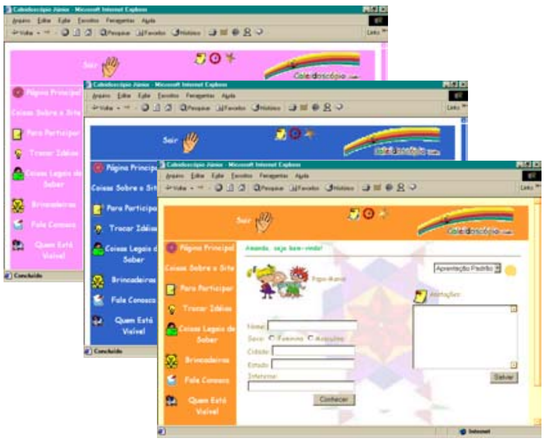

FIGURA. 5
INTERFACE DO PORTAL CALEIDOSCÓPIO JÚNIOR.

CONCLUSÃO

A metodologia de trabalho apresentada serviu como base para definição da estrutura do portal Caleidoscópio Júnior e configuração de uma primeira versão a ser avaliada com crianças.

Seu desenvolvimento continuará através de um processo incremental, ou seja, sua utilização irá definir os conteúdos e outras ferramentas adequadas ao seu contexto de uso.

Além da criação de novos conteúdos e ferramentas, faz-se necessário o projeto e a implementação de um ambiente de administração dos dados do portal. Hoje essa administração é realizada através de uma interface Web que possibilita o envio de consultas SQL ao servidor de banco de dados da aplicação – uma tarefa que ainda requer conhecimento especializado do sistema.

Ainda, como uma das propostas do portal é permitir que crianças troquem idéias de forma mais livre, através dos mecanismos de comunicação já disponíveis no portal, será preciso restringir seu uso, em um primeiro momento, a projetos e atividades escolares, onde elas não ficariam tão expostas às "inseguranças" da Web.

AGRADECIMENTO

Agradecemos a participação valiosa de Maria Cecília Martins e Raquel Zarattini Chebabi no planejamento, participação e discussão das atividades realizadas com as crianças. Este trabalho contou com apoio do CNPq.

THE IMPORTANCE OF ENVIRONMENTAL PROTECTION AND PROFESSIONAL ETHICS TO ENGINEERING AND TECHNOLOGY DEPARTMENTS IN HIGHER EDUCATION

Muthar Al-Ubaidi[1] and Mark Fritz[2]

Abstract — *As nations spend billions of dollars cleaning up environmental mistakes from decades of abuse, the question arises of what role institutions of higher education may play in preparing future professionals to prevent environmental destruction. Primary and secondary educators in the United States have, over the past decade, incorporated programs into their curricula designed to develop student sensitivity to the environment. Institutions of higher education, however, may lag behind. We believe that assessing the current practices of higher education in teaching environmental protection and professional ethics could provide critical information for improving educational practices. To obtain this critical information, we developed a pilot survey to explore the extent to which courses in environmental protection and professional ethics are taught within higher education. The survey was sent to 2000 educators representing undergraduate and graduate programs in engineering, science, and technology. The survey results suggest that professional ethics courses may be widely taught, but environmental protection courses are not.*

Index Terms — *environment, ethics, pollution.*

INTRODUCTION

Human survival depends on a number of natural resources. Water is certainly one such resource; air is another; and energy sources such as fossil fuels are a third. Reviewing the presence and effects of pollutants in each of these natural resources is a helpful way to begin a discussion of the role of higher education in preparing future professionals to prevent environmental destruction.

Water. Water is a resource with unique properties, essential to all life. It is a basic factor in the growth of natural communities and human civilizations. The safety of a drinking water supply is influenced by impurities that fall into three classes: organic chemicals, inorganic chemicals, and microorganisms. Discharge of wastewater represents a growing threat to water supplies by adding all three of these impurities to water resources. Wastewater from cities, industries, mining operations, farms, and rural homes contains organic, inorganic, and microorganism impurities that can and do contaminate drinking water supplies. If organic pollutants present in wastewater are not removed, they can rob water of the dissolved oxygen normally present. Also, organic chemicals such as pesticides may directly poison aquatic organisms, including those connected to human food supplies. Inorganic chemicals in wastewater such as certain phosphorus and nitrogen compounds can cause excessive overgrowth of algae. Microorganisms in discharged wastewater are a major cause of disease [1]. For many years industrial and municipal wastes have been buried in landfills, in abandoned wells and mines, or discharged directly into rivers and other bodies of water. Only recently have we come to better understand how these practices can pollute groundwater which was once thought to be the safest source for drinking water.

Air. Air is as essential as water; however, numerous pollutants taint the air we breathe. Misuse of fossil fuels has polluted the air so severely that in some regions it is a significant cause of death [1]. Solid particles such as lead, asbestos, and soot are dispersed in the air. Liquid droplets of hydrocarbons and sulfuric acid float in the atmosphere. Gases such as carbon monoxide, nitrogen oxides, and sulfur dioxide are mixed in the atmosphere that surrounds us. These pollutants may impair breathing and exacerbate heart and lung diseases. The landscape is also influenced because forests and other vegetation are sensitive to air pollutants. Construction materials such as mortar and metal are corroded by some of these pollutants. Smog and acid rain are a few other examples of the effects of air pollution.

Energy Sources. Energy sources are essential and commonly used in three ways. First, the energy released by mining and burning fossil fuel may be used directly as heat. Second, the heat energy might be converted into work, using refined oil to run machinery and power automobiles. Third, the heat energy from either fossil fuel or nuclear sources may be converted to electricity. All of these uses of energy discharge pollution in forms that can range from waste heat, to many of the air pollutants mentioned above, to radioactive materials.

The last few decades have seen a strong movement begin to clean the environment from these pollutants released by new technologies and lack of concern for their effects. This lack of concern may be due to the dearth of understanding by engineers of the effects of these technologies on the environment, and also to a preference

[1] Muthar Al-Ubaidi, University of Cincinnati, College of Applied Science, Mechanical Engineering Technology Department, 2220 Victory Parkway, Cincinnati, Ohio, 45206, USA
[2] Mark Fritz, University of Cincinnati, College of Applied Science, Chemical Technology Department, 2220 Victory Parkway, Cincinnati, Ohio, 45206, USA

for economic factors over ethical factors. Nonetheless, cleanup costs may be shown to be many times greater than the cost of educating engineers to protect the environment and to build in them strong ethical behavior to protect natural resources.

EXAMPLES OF CLEANUP COSTS

Cleaning up pollution is expensive. The average cost to clean a contaminated groundwater site under the U.S. Superfund cleanup program, for example, is $25 million [2]. Cleaning up some polluted sites is even more expensive than this average. For example, cleaning up lead-contaminated soil and groundwater from an eastern U.S. site where automobile batteries were discarded will cost an estimated $40 million [3]. And the cleanup cost of toxic metal and acid releases from California's Iron Mountain Mine is estimated to approach $1 billion [4]. Thousands of such polluted sites can be found worldwide, and estimating the cost to clean up all of these sites is likely to yield a staggering number. In the U.S. alone, estimates place the total cost of cleaning up all the private and public polluted sites as high as $500 billion to $1 trillion [5].

In addition to paying for cleanup, the high cost of pollution is often incurred in terms of human health. Some human costs are local. For example, in the Great Lakes region of the U.S. and Canada, children born to women who have high levels of PCBs (polychlorinated biphenyls) from widespread improper disposal suffer retarded growth and score significantly lower on certain memory tests [6]. Other human costs are global. In 2002, the World Health Organization listed unsafe water as one of the top ten health risks worldwide [1]. Widely-read publications indicate that an estimated 1 billion people worldwide drink contaminated water [7]. Also worldwide, urban air pollution killed an estimated 800,000 people in 2002. Lead pollution killed an estimated 234,000 people [1].

These few examples illustrate the high cost of pollution, both in terms of the money required for cleanup and in terms of the impact on human health. The cost of pollution is many times greater than the cost of educating engineers to protect the environment and its natural resources.

A CHALLENGE FOR ENGINEERING AND TECHNOLOGY EDUCATORS

Most engineering and technology educators would agree that environmental protection is a matter of primary importance to humans and to the future of humanity. Some of us also feel a sense of frustration, of "where can I begin?", "how can I help?" or "what are my roles and responsibilities?" Some of us fear that we do not know enough or that we are just "amateurs," unlikely to have any significant impact whatever we do. Others ignore the issue hoping that it will go away. These thoughts were the driving force behind our desire to survey educational institutions regarding their courses in environmental protection and professional ethics.

PILOT SURVEY OF EDUCATIONAL INSTITUTIONS

A four-question pilot survey was designed to explore the extent to which environmental protection and professional ethics are taught in undergraduate and graduate institutions in engineering, science, and technology. The survey was sent by e-mail to over 2000 educators around the world. The four survey questions are listed below as the captions to Figures 1-4.

Sixty educators responded to the survey. Almost all of the respondents taught in engineering and technology programs. Most of the respondents (42) were in the United States. Other respondents were in Latin America (8), Asia (5), the Middle East (4), and Europe (1). Survey results were tabulated by location and by discipline. Two locations were considered, the U.S. and other countries as a whole. Other countries were considered as a whole because of the small number of non-U.S. respondents. Three groups of engineering and technology programs were considered: those in the civil, mechanical, and electrical/computer disciplines.

RESULTS

The first survey question asked respondents if their institution has a department in the field of environmental or green engineering. As illustrated in Figure 1, 64% of all respondents indicated that their institutions have no such departments. When responses from the U.S. were collected and compared to responses from other countries as a whole, the results for the two groups were almost identical. In the U.S., 64% indicated no environmental or green engineering department. In other countries as a whole, 65% indicated no such department.

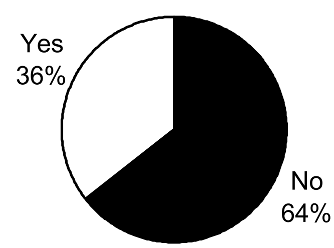

FIGURE 1
DOES YOUR INSTITUTION HAVE AN ENVIRONMENTAL OR GREEN ENGINEERING DEPARTMENT?

The second survey question asked respondents about required courses in their department on environmental protection. As illustrated in Figure 2, 69% of all respondents indicated that they have no required courses in environmental protection. When divided into responses from the U.S. and responses from other countries as a whole, the results were 70% no required courses for the U.S. and 66% no required courses for other countries. Among disciplines, respondents from civil engineering departments were most likely to indicate one or more required courses. In these civil engineering departments, only 34% of respondents indicated no required courses, in contrast to the 69% rate for all respondents shown in Figure 2. Electrical/computer engineering departments were most likely to indicate no required courses. In these departments, 92% of respondents indicated that they had no required courses in environmental protection.

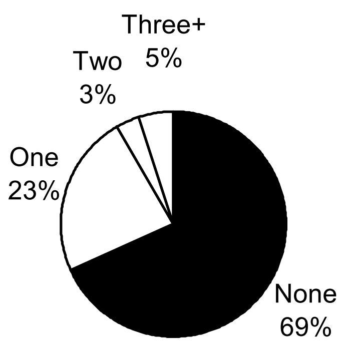

FIGURE 2
IN YOUR DEPARTMENT, HOW MANY REQUIRED COURSES ON ENVIRONMENT PROTECTION DO YOU HAVE?

The third survey question asked respondents about optional or elective courses in their department on environmental protection. As illustrated in Figure 3, about half of all respondents—52%—indicated that they offer no optional or elective courses in environmental protection. Results from the U.S. suggest that other countries as a whole may be more likely than the U.S. to offer optional and elective environmental protection courses. In the U.S. 55% indicated no optional or elective courses; in other countries as a whole only 44% indicated no optional or elective courses. Among disciplines, the results were similar to those above for required courses, with respondents from civil engineering departments being least likely to indicate that they had no optional or elective courses. Respondents from electrical/computer engineering were most likely to indicate that they had no optional or elective courses.

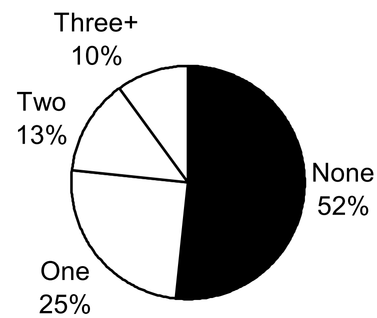

FIGURE 3
IN YOUR DEPARTMENT, HOW MANY OPTIONAL OR ELECTIVE COURSES ON ENVIRONMENT PROTECTION DO YOU OFFER?

The fourth and final survey question asked respondents about courses offered in ethics and professional responsibilities. As illustrated in Figure 4, 24% of all respondents indicated that their department or college offers no such courses. Results by location suggest that other countries as a whole are more likely than the U.S. to offer no ethics and professional responsibility courses. In other countries as a whole 44% of respondents indicated offering no such courses. In the U.S. only 15% of respondents indicated offering no such courses. Among disciplines, civil engineering respondents were most likely to offer no such courses (56% indicated none.) Mechanical engineering respondents were least likely to offer no such courses (30% indicated none.)

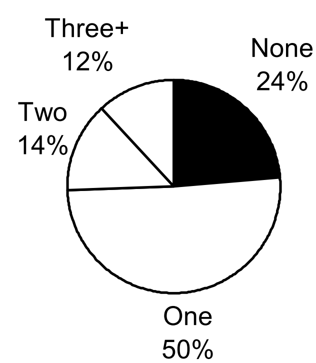

FIGURE 4
IN YOUR DEPARTMENT OR ELSEWHERE IN YOUR COLLEGE, HOW MANY COURSES IN ETHICS AND PROFESSIONAL RESPONSIBILITIES DO YOU OFFER?

CONCLUSION

The results of the pilot survey help reveal the extent to which environmental protection and professional ethics are taught in undergraduate and graduate programs in engineering and technology. The survey results suggest that professional ethics are widely taught in these programs. Adding percentages in Figure 4 shows that a total of 76% of the respondents indicate offering one or more courses in ethics and professional responsibilities. In contrast, except for civil engineering, most engineering and technology programs appear to pay little attention to environmental protection courses. Adding percentages in Figures 2 and 3 shows that a total of only 31% of respondents indicate courses in environmental protection that are required; only 48% indicate courses that are optional or elective.

The low response rate to the pilot survey (60 respondents out of 2000 contacted) is consistent with the conclusion that most programs pay little attention to environmental protection courses. Also, educators in programs with interest in environmental protection may be more likely to respond to a survey on that topic. As a result, the survey results may even overestimate the true extent of environmental protection coursework in engineering and technology disciplines.

Why so little interest in environmental protection courses? One possible explanation lies with the industries that we serve. Because educators adapt curricula to meet industry needs, industry is a major driving force in the curriculum. Industry may simply not be interested in students who have completed courses in environmental protection. We propose that educators could improve the engineering and technology disciplines, however, by being proactive. The huge costs of pollution and its cleanup are borne by all of us, either directly through our health or through the cleanup costs to industry and taxpayers. By improving education for our students about the consequences of pollution, we can lead change in industry and reduce the costs of pollution and its cleanup.

To build on this pilot study, we plan to survey educators further to increase the number of respondents. Our goal is to create a more complete picture of the state of environmental protection education in engineering and technology departments.

ACKNOWLEDGMENT

We thank Maria Kreppel for critically reading a draft of this paper and for making helpful suggestions.

EFFECTS OF CONTROLLED RAMP-DOWNS/UPS FOR CRYOGENIC PROCESSING OF RAPID PROTOTYPED MATERIALS

J. Jackson[1], G. Chapple[1], J. Do[1], X. Zhuang[1], M. Mendelson[1], R. Noorani[1], B. Fritz[2]

Abstract — *Rapid Prototyping (RP) turns a virtual three-dimensional drawing into a solid structure and useable part. Increasing the material properties of RP materials allows rapid prototyped parts to be employed in a wider variety of applications. The major goal of this study is to increase the scope of usage of RP materials through cryogenic processing by optimizing the combination of strength and ductility for the stereolithography photopolymer epoxy resin DSM Somos 8110. The research will investigate (1) the effects of cryogenic processing of prototyped samples, (2) the effects of controlled ramp-downs/ups on the ultimate and tensile strengths of samples,(3) the equipment and procedures used, (4) the results and analysis of the experimental data. Test specimens of RP thermosetting resin (DSM-Somos 8110) were fabricated and cryogenically aged from 10-25 hours. The tensile strength and impact toughness were measured.*

Index Terms — *Rapid prototyping materials, cryogenic processing, tensile and ultimate strengths*

INTRODUCTION

The primary objective of this research is to apply cryogenic processing to Rapid Prototyped materials. Cryogenics is the science and art of producing cold. It started in 1877 when two scientists, Cailletet in Paris and Picet in Geneva, developed a procedure to liquefy oxygen in a laboratory[1-2]. Nowadays, nitrogen and helium are the most common cooling media. Since the normal boiling points of nitrogen and other permanent gases such as helium, oxygen and argon are about 120K (approx. –244 ^{o}F), the cryogenic temperature is generally considered 120K or below [3-4].

Cryogenic processing is one of the most important fields in industry today [4]. It helps to reduce costs for industry and increase industrial efficiency. For example, industrial application has reported 195% to 817% increase of wear resistance for standard steel that was cryogenically treated [5]. The cryogenic process consists of 3 stages based on time and temperature variables. This process starts with gradual ramping down of temperature to a specific point, then the temperature is held at that point for a period of time, then the temperature is brought up to room temperature . As a result of this deep cooling and heating cycle, molecular changes occur, binding the atoms in the metal together [4].

Over the last 10-20 years, not much research has been conducted on cryogenic processing. Most research that was done on cryogenics was on metals. Rapid Prototyping (RP) is a new technology that takes information from a computer-aided design file and makes a 3D part by building it one layer at a time [5]. When RP was first introduced in the late 80's, the materials used to produce the parts had low yield strength. Our research attempts to show that the strengths of RP materials can be increased by cryogenically processing the samples before its industrial applications. As mentioned before, in all the cryogenic work, the scientists and engineers basically lowered the temperature of the sample to cryogenic condition very fast, held it to the temperature for a few hours and then ramped up the temperature as fast as possible [4,5]. Two years ago, the author did research on the cryogenic processing of both ABS plastic from Fused Deposition Modeling (FDM) and DSM SOMOS 8110 using Stereolithography Apparatus (SLA)-250 machines. While the cryogenic processing did not have much effect on ABS plastic, the yield strength of DSM SOMOS was increased between 25-50% [6]. The author believes the ramp-down and ramp–up conditions might make a significant contribution to the increase in strength of the polymer samples.

The author has recently developed a Data Acquisition System (DAS) using LabVIEW from National Instruments that provides us the programming power for the ramp-down and ramp-up conditions. The conventional and proposed cryogenic processes are shown in Figures 1and 2.

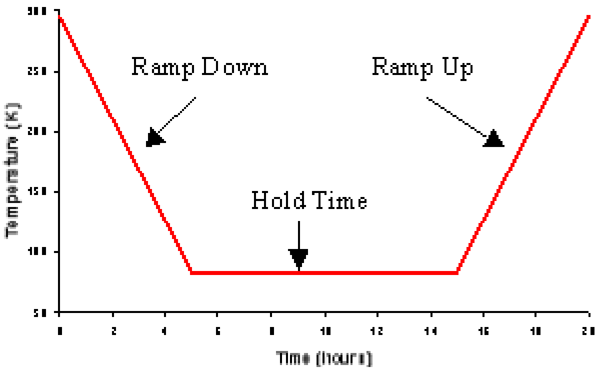

FIGURE 1 CONVENTIONAL CRYOGENIC PROCESSING

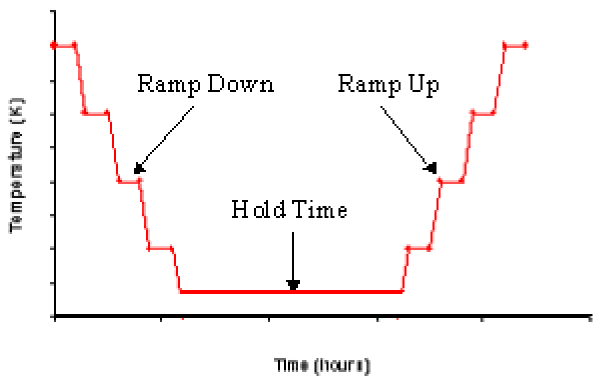

FIGURE 2 PROPOSED CRYOGENIC PROCESSING

NSF REU PROGRAM AT LMU

LMU received an NSF grant two years ago to establish a research experience for undergraduates (REU) site. The objective of the proposed REU site program is to provide, each year, 20 community college students and four LMU students the opportunity to engage in engineering research on meaningful projects during a ten week summer period. Community college participants are recruited from the twenty community colleges in closest proximity to LMU. A further objective is to attract students from those groups traditionally under-represented in the engineering profession. The work is conducted under the guidance of two faculty who has much successful experience in directing undergraduate students in research work. The results of the research are published in journals and reviewed conference proceedings. The goal of the program is to inspire the students to complete their undergraduate study and go on to participate in research at the graduate level.

EXPERIMENTAL PROCEDURE

Equipment and Process

The following major equipment was used in this research.

1. Northrop Grumman SLA-250 RP Machine
2. Cryogenic Treatment Equipment
3. Instron Tensile Testing Machine
4. Izod Impact Tester
5. Scanning Electron Microscope (SEM)

The experimental setup if shown in Figure 3.

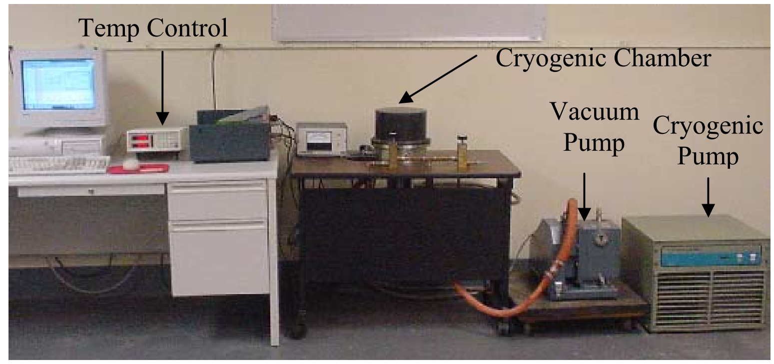

FIGURE 3. EXPERIMENTAL SETUP FOR CRYOGENIC PROCESSING.

The following outlines the steps used in the experimental process that was used to design, fabricate, test and analyze the samples.

1. Design Dog Bone and V-Notch Samples
2. RP Machine Builds Parts from Design
3. Expose Parts to Cryogenic Treatment with Liquid He.
4. Tensile and Impact Testing

The programming of the temperature controller using LabVIEW 6i is shown in Figure 4.

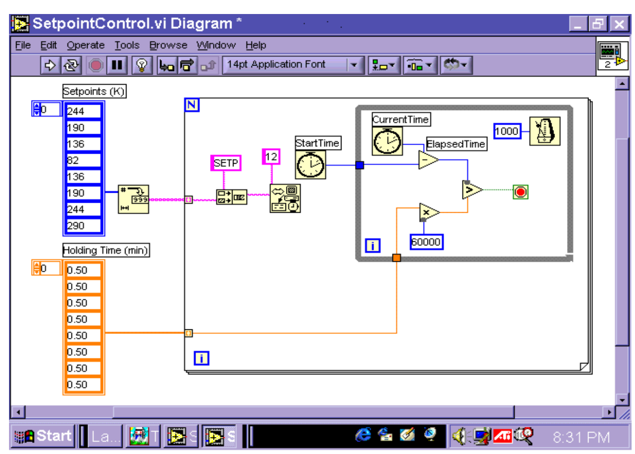

FIGURE 4. TEMPERATURE SETPOINT VI DIAGRAM

Designing and Prototyping the Samples

Drawings of the dog bone and v-notch shaped samples were created using AutoCAD (Figs. 5A and 5B) and these were saved as separate .DWG files. These files were then converted into STL format for use with stereolithography software. SLA-250 (Northrop Grumman) RP machines was then used to rapid prototype the parts.

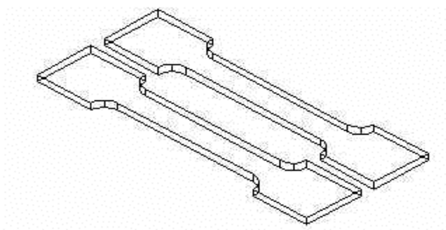

FIGURE 5A. TWO DOG BONE-SHAPED SAMPLES.

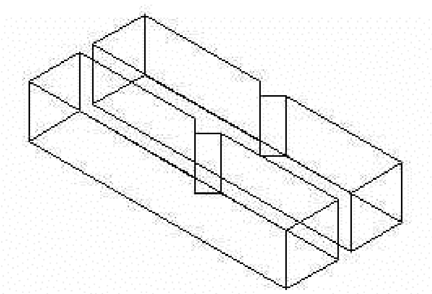

FIGURE 5B. TWO V-NOTCH-SHAPED SAMPLES.

Cryogenic Treatment

The following process was used to cryogenically treat each sample.

1. All samples except the baseline went through cryogenic treatment before testing. The samples were prepared at Northrop Grumman, and cryogenically aged at Loyola Marymount University.
2. The cryogenic process is characterized by three parameters: ramp-down time from room temperature to 88K (–300^{o}F), hold time at 88K, and ramp-up time from 88K to room temperature.
3. Preliminary experiments were performed on cryogenic treatment. The ramp-down time of 14 hours was used. Three holding times of 10, 15 and 20 hours, and ramp up times of 14 hours were used.

Samples are labeled as follows: XX-XX-XX. The numbers represent the ramp-down time, holding time and ramp up time, respectively, in hours. (e.g: 14-10-14 means that the samples were ramped-down in 14 hours, cryogenically aged 10 hours, and then ramped-up in 14 hours.)

Tensile Testing and Izod Impact Testing

The yield and ultimate strengths of the samples were measured using the Instron Universal Testing Instrument 4500. The cross-head speed of the test machine was 0.0212 mm/s. The interface with the machine was performed using the front panel and a software program running on a desktop computer. Izod impact testing is performed to determine the toughness of a material. The sample is made with a centered v-shaped notch. During the impact testing, the sample is subjected to a quick and intense blow by a hammer pendulum. The impact test evaluates the material's resistance to crack propagation. The impact energy absorbed by the sample during failure is determined by calculating the difference in potential energy of the hammer.

RESULTS AND DISCUSSION

Tensile and Impact Testing

The results of the yield strength and ultimate strength vs. cryogenic treatment time (0-20 hours) are shown in **Figures 6A, 6B.** In both cases, the strengths appear to be affected by aging time. To verify these results, the data were statistically analyzed using multiple t-testing, which compared the means of two treatments at-a-time at a 0.05 level of significance [7]. A one-way analysis of variance (ANOVA) could not be used, because the variances of the treatments were unequal. For the yield strength data (**Figure 6A),** it was determined with 95% confidence that the means of the treatments were statistically insignificant. Due to the large variances at 15 and 20 hours, we can say that there was no significant increase in the yield strength with aging time.

For the ultimate strength (**Figure 6B)** vs. aging time, the data were analyzed in the same way. Again, one-way ANOVA could not be used. Multiple t-testing on the treatment means showed that for 95% confidence two conclusions were reached: (1) the mean strengths at 0, 10 and 20 hours were equivalent, and (2) the mean strength at 15 hours was significantly lower than that at 10 and 20 hours. Hence, aging time produced a drop in the ultimate strength between 10 and 15 hours. Otherwise, there was no significant effect of cryogenic aging on the ultimate stress.

The effects of ramp-up times on the yield strength and ultimate strength are shown in Figures 7A and 7B. In both cases, the strengths appear to be negatively affected.

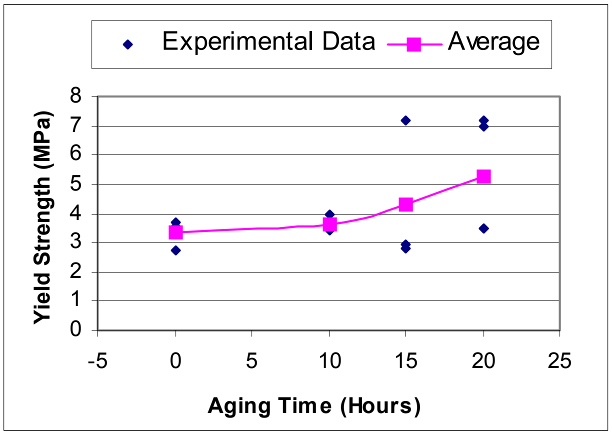

FIGURE 6A. YIELD STRENGTH VS. CRYOGENIC AGING TIME.

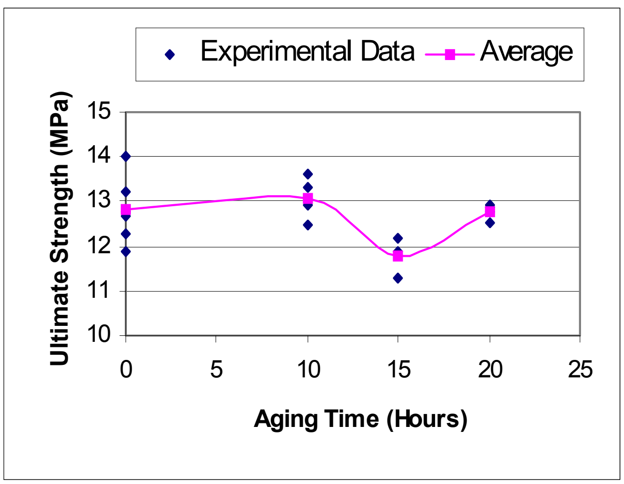

FIGURE 6B. ULTIMATE STRENGTH VS. CRYOGENIC AGING TIME.

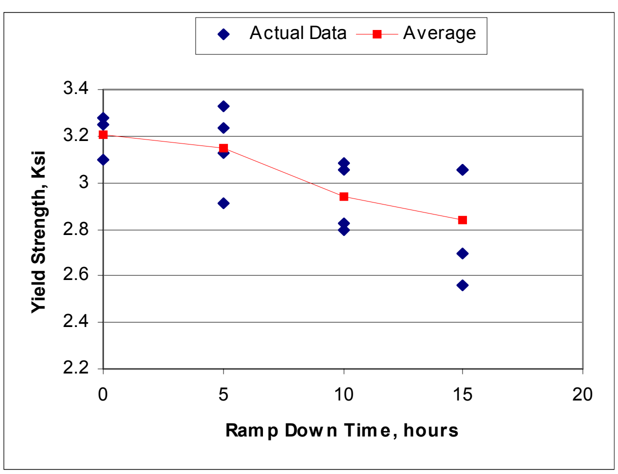

FIGURE 7A. YIELD STRENGTH VS. RAMP-DOWN TIME

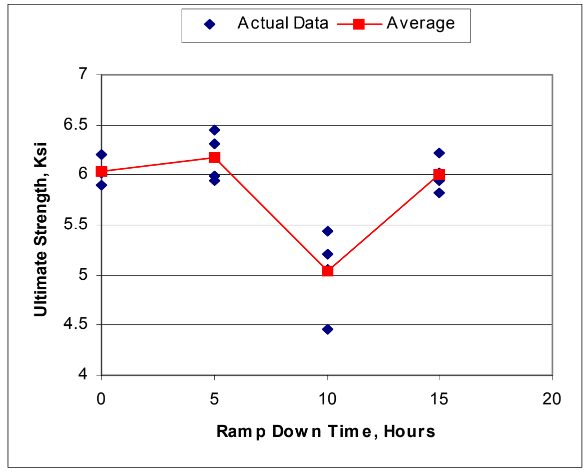

FIGURE 7B. ULTIMATE STRENGTH VS. RAMP-DOWN TIME

CONCLUSIONS AND RECOMMENDATIONS

Based on the findings from our research, the following conclusions and recommendations can be made:

1. DSL-Somos 8110 test specimens were fabricated by stereo-lithography using SLA-250 RP equipment. The specimens were laser cured by pulling the specimens parallel to the tensile axis.
2. The test specimens were cryogenically treated by a ramp-down cycle from room temperature to 88K in 14 hours, a hold cycle of 10 - 20 hours, and then a ramp-up cycle from 88K to room temperature in 14 hours.
3. Due to large data scatter, the yield strength and impact energy were not affected by cryogenic aging treatment. Only the ultimate strength exhibited a significant decrease with aging treatment from 10 to 15 hours.
4. The yield strength of slower ramp-down decreased exponentially while the ultimate strength did not show any positive increase, indicating that the slower ramp-down did not have any effect on the cryogenic processing of DSM SOMOS 8110.
5. It was expected that the wide data scatter was caused by microscopic steps and their associated defects at the fillet radius of the tensile specimens. Samples with steps and defects had lower strengths, and those without steps and flaws had high strengths. The variability in the surface texture of the fillet radius caused a wide variability in the tensile strength and impact energy.
6. For future work, it is recommended that the SLA specimens be rapidly prototyped normal to the face of the dog-bone specimen. This will hopefully reduce the data scatter, which currently masks any potential effect of cryogenic aging time on the tensile strength and impact energy.

ACKNOWLEDGEMENTS

The work was partially funded by an NSF Grant under Research Experiences for Undergraduates (REU). The authors also appreciate the support provided by the Northrop Grumman Corporation.

EDUCATIONAL PROGRAMS IN HIGH-TECH

Alexander I. Chuchalin, Mikhail A. Soloviev

***Abstract** – During the last years Tomsk Polytechnic University (TPU) has successfully followed world trends in the evolution of education. One of the prospective strategies is innovative international educational programs development and implementation. Now the stress is laid upon innovative activity in Masters Degree Programs in Hi-Tech. The basis these programs is integration of the scientific and educational potential of TPU and academic research institutes in Tomsk; international cooperation with the foreign universities; innovative technology of studies. In the 2003/04 academic year TPU calls students' attention to six M.Sc. Programs: in Material Science (Computer Design of New Materials, MegaElectronics), in Electrical Engineering (Discharge and Plasma Technology, Methods and Instruments for Non-Destructive Quality Testing), in Applied Physics (Physics of Condensed Matter, Generation and Application of Electromagnetic Radiation). The aim of this paper is to present the TPU practical experiences in development of innovative educational programs, and to encourage foreign partners to take part in the implementation and development of new educational programs.*

Index Terms – Masters degree program, e-learning studies, international cooperation, innovative technology of studies.

Tomsk Polytechnic University, the first higher educational institution (HEI) in Siberia, established on the initiative of the enlightened minds of the Russian intelligentsia, marked the beginning of the engineering education in the Asian part of Russia and trained more than 100 000 engineers for the years of its existence. [1] Today TPU includes eight institutes: The Institute of Language Communication, The Institute of Geology and Oil & Gas Industries, The Institute of Distance Learning, The Cybernetic Center, The Professional Development Institute, The Institute of Electrical Engineering, The Institute of International Education and The Institute of Engineering Education; eight faculties: Applied Physics & Engineering, Electrophysics & Electronic Equipment, Mechanical Engineering, Chemistry & Chemical Engineering, Thermal Power Engineering, Economics & Management, Humanities and Natural Science & Mathematics; three research institutes: Nuclear Physics, High Voltage and Introscopy. More than 20000 students take their studies in the university.

Tomsk Polytechnic University is the leading HEI, focused on the mobilization of intellectual elite, training of highly qualified specialists with the broad scientific views. Its' graduates work in the leading Russian and foreign scientific centers. The university actively pursues a policy of integration in world educational space; international contacts of the university are intensively developed, including contacts with educational and scientific establishments in the USA, Great Britain, Germany, France, Japan, Cyprus, Southern Korea, China, India, Vietnam and others. [2]

One of the prospective trends is development and realization of international educational programs. In 1998 the strategy of educational services export to ex-USSR countries and foreign countries was developed at TPU.

The first experience was gained by realization of international Bachelor Degree Programs. At present more than 60 international students take their Bachelor Degree studies at TPU (Electrical Engineering, Material Science, Chemistry, Computer Science, Environmental Protection and others). The Global Alliance for Transnational Education (GATE, USA) awarded certification to TPU Bachelor Degree Programs. Today the programs are in the process of accreditation and validation by Open University Validation Services (OUVS, UK) and the Accreditation Board for Engineering and Technology (ABET, USA). [3]

The next step was the development of international Masters Degree Programs. The year 2000 saw the initial preparation of Masters Degree Programs in High-Tech. Multi-stage system of education and Masters Degree Programs have existed in Russia since 1994. At present Tomsk Polytechnic University has 65 Masters Degree Programs in 16 fields of study. Special requirements are established for Masters Degree Programs for the international market. In accordance with the results of the university contest, the development of the six pilot Masters Degree Programs in High-Tech were started in cooperation with the leading scientific and research institutes of Tomsk (Nuclear Physics, High Voltage, Non-Destructive Testing, Institute of Strength Physics and Materials Science of Russian Academy of Science and others). It represents a uniquely innovative project. The Masters Degree Programs are synthesized on the basis of the Russian educational standards and the educational programs of the leading foreign universities. As a result, foreign students recognize the programs, which retain the best traditions of Russian high school, scientific and the methodical experience of Tomsk Polytechnic University.

These Masters Degree Programs in High-Tech represent three fields of knowledge:

Material Science
Specialization: Computer Design of New Materials
Specialization: MegaElectronics

Electrical Engineering
Specialization: Discharge and Plasma Technology
Specialization: Methods and Instruments for Non-Destructive Quality Testing

Applied Physics
Specialization: Physics of Condensed Matter
Specialization: Generation and Application of Electromagnetic Radiation

Masters Program – Computer Aided Design of Advanced Materials and Technologies (M.Sc. in Materials Science)

The Masters program is developed and administered by Mechanical Engineering Faculty, TPU. Institute of Strength Physics and Materials Science (ISPMS) of The Russian Academy of Science highly qualified professors, modern laboratory equipment of ISPMS (automated laser measuring system, optical microscopes, atom and scanning tunneling microscopes, X-ray installations and a unique optic-television installation for the testing of plasticity and strength of materials of the new generation) are engaged in the studies process. The scientific basis of the program includes the following topics:

Metals science and Mesomechanics of materials after surface hardening;

Materials Science and Technology of new constructional and tool materials;

Metals science, Computer aided design and the technology of surface treatment.

Masters Program – MegaElectronics (M.Sc. in Materials Science)

“MegaElectronics” is widely used in the modern industry with products whose value is in the trillions of dollars.

“MegaElectronics” studies:

Fundamental principles and technology of the particles fluxes generation and forming;

Principles and mechanisms of the sources of fluxes operating;

Principles and laws of the interaction between particles and plasma fluxes and substance;

The basic processes and phenomena, initiated by particles and plasma fluxes;

Modern technological equipment for beam and plasma treatment of materials.

The Program is run by the Faculty of Natural Sciences and Mathematics in cooperation with the TPU Research Institute of Nuclear Physics in company with our highly professional foreign partners – the University of Rostok, Germany and Ecole Polytechnique, Palaiseau, France.

TABLE 1
M.SC. IN MATERIALS SCIENCE

	M. Sc. in Material Science	
	MegaElectronics	Computer Design of New Materials
1st semester	Core Courses	
	• Modern Issues of Science (in Material Science)	
	• Computer-aide Technology in Science	
	• Theory and Properties of Crystals and Disordered Materials	• Diagnostics of Loaded Materials and Constructions
	Electives	
	• Effectiveness of High Technology • Project Management	
2nd semester	**Specialization Courses**	
	• Interaction of Charged Particles and Radiation with Matter • Physics of Atoms, Ions, Molecules, and Chemical Bonds. Plasmochemistry • MegaElectronics of Dielectrics, Semiconductors and Metals	• Mesomechanics and Computer Simulation of Materials • Modern Technology of Coating and Surface Hardening • Thin Films and Multilayer Materials for Electronics
3rd semester	• Defects in Solids • Generation and Application of Synchronized Pulse Electron and Ion Beams • High-Energy Pulse Electron and Ion Treatment of Materials	• Metal and Ceramic Based Nanostructural Materials • Simulation of Ceramic Materials Based on Silicate and Oxide Systems
4th semester	Master’s Thesis	

Masters Program – Discharge and Plasma Technology (M.Sc. in Electrical Engineering)

At present “Discharge and Plasma Technology” includes:

Destruction of materials and products;

Rock crushing;

Fragmentation of products and wastes;

Recovering and cleaning of heat exchangers;

Generation of ozone and ultraviolet radiation, air, water and sewage refinement;

Materials and products hardening;

Products and materials functional coating;

Modification of substance surface and properties.

The Masters Program is run by the TPU Institute of Electrical Engineering, The TPU High-Voltage Research Institute and the Institute of High-Current Electronics of the Russian Academy of Sciences.

Masters Program – Methods and Instruments for Non-Destructive Quality Testing (M.Sc. in Electrical Engineering)

The scientific basis of the Masters Program is exemplified by the advanced achievements of TPU Research Institute of Introscopy. The Department of Physical Methods and Instruments for Non-Destructive Quality Testing and the TPU Research Institute of Introscopy comprise a unique scientific and technical complex, which undertakes research in the field of Methods and Instruments for non-destructive quality testing and diagnostics of products, materials and constructions. The devices and methods, developed here, enable to test a wide range of products from miniscule objects of radioelectronics to large-sized constructions. The program is run in cooperation with the University of Saarbrucken.

TABLE 2
M.SC. IN ELECTRICAL ENGINEERING

2nd semester	**Specialization Courses**	
	• Generation and Measurement of High Voltage and High Current Signals • Theory and Properties of Crystals and Disordered Materials • Physics of Low-Temperature Plasma and Technology for Material Treatment	• Radioactive Diagnostics • Acoustic Diagnostics • Measuring Instruments
3rd semester	• Electrical Discharge Technology for Material Treatment and Fragmentation • High-Energy Pulse Electron and Ion Treatment of Materials • Beam-Radiation Technology of Materials' Modification	• Electromagnetic Diagnostics • Infra-Red Testing • Statistical Analysis and Quality Management • Methods of Direct Diagnostics
4th semester	**Master's Thesis**	

Masters Program – Physics of condensed Matter (M.Sc. in Applied Physics)

This Masters Program is aimed at training specialists in the field of research of surface, nearsurface layers of solids and thin films; development of new technologies for creating materials with particular electrophysical properties; nuclear physics; the interaction of radiation with substance. The Masters Program is run by the Faculty of Natural Sciences and Mathematics in cooperation with the TPU Research Institute of Nuclear Physics, Universitat des Saarlandes and the Frauhofer Institut Zerstorungsfreie Pruferfanner (Saarbrucken, Germany).

Masters Program – Generation and Application of Electromagnetic Radiation (M.Sc. in Applied Physics)

Training of Masters in the field of generation of electromagnetic radiation beams is carried out by the Faculty of applied Physics and Engineering, TPU. The department studies new techniques of generating electromagnetic radiation in cooperation with the scientists of Hiroshima University in Japan. The educational process uses modern laboratory equipment of the departments of the TPU Research Institute for Nuclear Physics, the Institute of High-Current Electronics of the Russian Academy of Sciences and the Department of Applied Physics at TPU.

	• Non-Linear Physics • Quantum Mechanics • Fractal theory	
2nd semester	**Specialization Courses**	
	• Special Physical Practicum • Isotope, Chemical and Structural Analysis of the Surface • Experimental Methods for Studying of Solids • Theory and Properties of Crystals and Disordered Materials	• Special Physical Practicum • Interaction of Charged Particles and Radiation with Matter • Physics of High-Energy Accelerators • Modern Sources of X-ray and Gamma Radiation • Application of Accelerators in Industry and Research
3rd semester	• Hydrogen in Metals and Alloys • Computer Simulation in Physics • Scanning microscopy	• Radiation Effects in Condensed Matter • Generation of Radiation with Relativistic Electron Beams • Monte-Carlo Method in Theory of Radiation Transport • Simulation of Radiation Transport by Using "GEANT" Code
4th semester	**Master's Thesis**	

The technology Masters Programs realization is interesting enough. The normative period of studies for Masters

Degree is two years in accordance with the State educational standard. The educational program includes core courses, specialization courses, electives, scientific and research students' work and the preparation of a master's thesis.

TABLE 4
PROGRAM OF STUDIES

Courses	Credits
Core Courses	12
Specialization Courses	16
Electives	4
Research	4
Master's Thesis	6
Total Required for Graduation	42

The technology of studies assumes an element of distance learning (1st year) and laboratory practicum with preparation of a master's thesis based at TPU (2nd year). Distance learning assumes direct contact between student and professor at adjusting lectures and examinations (10% of the total time for distance learning) and independent work on the part of the student with teaching materials (textbook, tasks, testing materials), which are available in an Internet teaching environment. In the process of Internet teaching the student – professor dialogue is carried out by e-mail and by means of specialized chat-seminars. The first semester (17 weeks) is devoted to distance learning of core courses and electives. During the second semester (21 weeks) study process is structured as follows: 14 weeks of distance learning of theory of specialization courses of Masters Program and 8 weeks of studies in Tomsk laboratory and practical studies. The third and the fourth semester (2nd year) assumes studying of specialization courses, work on unique laboratory equipment in Tomsk, and as a result the defense of the master's thesis. Depending on his or her participation in research the student can be coauthor and coowner of any resulting project.

The unique aspect of any given Masters Degree Program is the fact that a part of the program (core courses, theory of specialization courses) is carried out on the branches of the university. This technology allows international students a portion of their period of study to live in their home country, to contact with the professors through Internet and listen toour professors' lectures in TPU branches. The TPU branch on the basis of Czech Technical University in Prague can serve as an example.

Thus, the TPU Masters Degree Programs have the following specific features:

The use of the newest scientific and technical developments, as well as the results of fundamental scientific researches, recognized in the world market;

The close integration of the TPU educational potentiality and scientific potentiality of Tomsk Research Institutes;

Joint realization of educational programs with the foreign universities-partners;

The innovative mechanisms of its' realization.

The Masters Degree Programs at TPU are original, fundamental and of universal application. They are characterized by the width of subject fields combined with the balance of theoretical and practical skills. The experience of pilot realization of the given programs in Tomsk Polytechnic University for Russian students in 2002/03 academic year demonstrated an interest from both students and the enterprises, which may employ them. It gives us hope that the given programs during the academic year 2003/04 will find consumer interest among international students. We hope as well that it will attract the attention of foreign universities with the aim of future cooperation in realization of TPU Masters Degree Program.

ENHANCING STUDENTS LEARNING IN ELECTRONICS THROUGH THE USE OF COMPUTERS AND LEARNING BOARDS

Smail Djirar[1]

Abstract — *This work uses available software tools to enhance student learning and to improve online delivery by the practical aspect added to the courses. Through the use available and easy to use software packages and applications learning boards online courses can be more interesting and attractive to students. The boards can also used to enhance the students learning outside normal classes. These learning boards are designed for Electronics Engineering courses. They can also be used in different modules of the curriculum. Students will get more skills by the use of more simulation packages such as Electronic Work Bench and Lab View. Through the whole process students get also to use different software applications such as PCB design software, Office applications. Several learning boards have been designed and built already.*

Each learning module can consist of but not limited to:

- *Construction guidelines of the circuit;*
- *Computer –based simulation to analyze the circuit;*
- *Practical activities related to the appropriate topic;*
- *Mathematical activities.*

A set of language activities for developing both written and oral skills, based on the technical content of the module can be added because our students are Arabic speakers.

The online teaching will be improved and the practical aspect is enhanced. The Virtual instruments are generated by Lab View software package. The Virtual Instruments are used for the necessary signal generations and measurements. All signal generations and measurements are done through a data acquisition card.

Once the goals and objectives of each module are specified, the boards can be used in different courses according to their mapping into the curriculum.

Index Terms — *E-learning, E-Lab, Online, Virtual Instruments.*

INTRODUCTION

This paper describes how the use of software and the introduction of computers (Laptops) have made easier and enhanced the learning of electronics courses.

Learning boards [4] have been developed to be connected to the laptops. The learning boards are give students the opportunity to have an e-lab. The e-lab consists of these learning boards and a virtual instruments software package.

The whole system consists of a set of software applications, a set of vitual instruments, a data acquisition card, and a set of learning boards. The method is then to give students a set of activities in Electronics related to theie courses. In the following sections all these components are described.

LEARNING MODULES

Learning modules are constructed by students on 160 mm over 100 mm printed circuit board. Students are asked to build a practical circuit on a pre-designed printed circuit board. They are are provided with construction guidelines and the necessary components. At this stage, students use also PCB design software (e.g. Niche).

The other software application, students after the construction of the board , is the use of a simualtion package. The simualtion allows studens to observe the behaviour of the circuit . The comptuer –based simulation for the whole project is Electronics Work Bench [1].

Once the test measuremnts are passed, students are rady to use their boards with laptops.

Each module contains the goals and objectives. Practical activities related to the appropriate topics have been designed.

[1] Smail Djirar , Faculty of Electronics Higher Colleges of Technology, PO BOX 25035, Abu Dhabi, United Arab Emirates, smadjir@emirates.net.ae

ELAB

The boards can be connected to a computer or a laptop. The connection is done through a data acquisition card. The card used in the project is a National Instruments card [2]. It has channels for analog inputs, anlog outputs, digital inputs and outputs.
Virtual Instruments are available, from National Instruments LabView [3] package, such as variable power supply, function generator , oscilloscope and digital multimeter. These instruments and the learning boards allow students to undertake all the practical activities designed for the learning modules. Figure 1 shows the elab system consisting of a laptop containing adata acquisition card connected to a learning module.

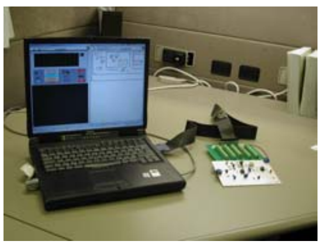

Figure 1: Elab system

The elab will be used soon in an online course. The course is on instrumentation and control fundamentals. One goal of this course is on signal conditioning. Students will be have the opportunity to do practical experiments related to this topic anywhere and anytime. They will have the possibilty to have more hands on activities outside the normal college hours.

ACTIVITIES AND CORRESPONDING SOFTWARE

As it was mentioned before, each learning module consist of several activities. Following are the acticities and their associated software:

- **Module construction**: At this stage students use a PCB design software such as Niche. A pre-designed printed circuit board
- **Simulation:** Simulation package such Electronic Work Bench helps students to investigate the behavior of the circuit. They can add, modify components. The aim is to get a clear idea about the response of the circuit for a given input.
- **Practical activities:** Pre-designed practical experiements are undertaken by students through the elab system, described previously.
- **Mathematical activities:** A maths activity sheet related to essential skills for circuit analysis is alos provided to students. This will give students a better of the theoritical concepts of the circuits.
- **Software applications activities:** A spreadsheet-based analysis of the circuit is also provided to students.

EXTENSION TO ONLINE COURSES

The Elab system is being extended to be used to online courses. It is being tested in particular with an online course. It is an introduction to instrumentation and control systems. The course investigates the basic principles of instrumentation and control systems, practical laboratories and industrial field trips. Topics include: examples of process control and automation systems, measurement systems, final control elements, signal conditioning systems, piping and instruments diagrams.

The focus is on signal conditioning. The goal is to investigate to the possibilty for students to undertake practical experiments using a laptop, a practical board and some Virtual Instruments as was mentioned previously.

CONCLUSION

The learning boards were tried with some students and they were very useful. Students enjoyed learning electronics. The main issue is that students were more interested because it applies to students with different learning styles.

The extension to the online course. The students were less confident at the beginnig but later they become more confident as they learned the logging process, and they other features of WebCT. They can build and test the learning boards. The next stage is to try the learning modules with their laptops.

INTEGRATING ENGINEERING CURRICULUM USING COMPUTER BASED MANUFACTURING TECHNOLOGIES

Vedaraman Sriraman[1]

Abstract *— Pressures due to global competition have forced manufacturers to continually diminish the product development time. In response to this challenge, time compression technologies are being used by industries to speed up the product development time. Time compression is effected through the application of such technologies as rapid prototyping (RP), Computer Aided Design (CAD), Computer Aided Manufacturing (CAM), rapid tooling and various casting and molding processes. It is important to expose engineering students to these computer-based tools. Rather than present these diverse tools in a piece meal fashion, it is important to expose students to the integrated applications of these tools in a capstone fashion. This paper details a National Science Foundation (NSF) funded project that was conducted at Southwest Texas State University (SWT) in which students were made to experience the entire product cycle from design through manufacture, using a "hands-on", integrated laboratory approach featuring the application of several time compression technologies such as rapid prototyping, rapid tooling, CAD and CAE.*

Index Terms — Curriculum Integration, Rapid Prototyping, Rapid Tooling, and Time Compression Technologies.

INTRODUCTION

This paper primarily describes an engineering curriculum integration effort that was carried out at SWT with support from NSF. The following summarizes the results of a literature survey that was used to drive our curriculum development efforts.

In a report published by the Society of Manufacturing Engineers (SME) entitled, "Manufacturing Education for the 21st Century: Manufacturing Education Plan" [1], the following competency were identified in current graduate engineers – concurrent engineering, product engineering, CAD/CAM, manufacturability, material selection and application and tooling. A survey conducted by the Mechanical Engineering Department [2] at Seattle University, in which nearly 100 manufacturing companies were asked to comment on current and future manufacturing practices and on curriculum recommendations, revealed that CAD, concurrent engineering and computer simulations were cited amongst the top ten manufacturing technologies. Based on these studies, it was concluded that it was important to teach the applications of rapid tooling and other time-compression technologies that center around RP such as CAD, CAE, CAM, investment casting, and injection molding [3]. Rapid tooling has been defined as tooling constructed from RP machine output and resulting in parts molded from production materials [4]. The concept of rapid tooling is becoming increasingly popular as a method of saving time and money [5].

In their NSF project of 1997 [6], Higley and Kin involved the use of industrial quality equipment to implement integrated design/manufacturing projects in which students could experience the complete product cycle from product inception through recycling. Based on these prior works, it was concluded that SWT's curriculum efforts would focus on:

- inclusion of RP, rapid tooling, CAD, CAM, other computer-based time compression technologies.
- the use of senior-level laboratory projects to provide students the opportunity to experience the entire product cycle. This would be effected by bringing to bear the integrated application of computer tools from several engineering courses to the solution of the senior project.

Once our goals were established, the next stage was the procurement of funds to support this initiative.

OUR APPROACH

The NSF was determined to be a primary funding agency with priorities that were similar to our goals. Therefore, in Fall 1998, a proposal was sent to the NSF that focused on curriculum development and capital equipment.

The project impacted three courses directly. These are TECH 2310 – Machine Drafting, TECH 4330 – Foundry and Heat Treatment, and TECH 4310 – Technical Drafting (now Tool Design).

The lower level machine drafting course was used as a vehicle for introducing the concept of design and rapid prototyping. Other lower level courses such as ENGR 2300 – Materials Engineering and TECH 2332 – Material Selection and Manufacturing Processes provided students background in materials and processing. Once these basics were individually covered in these lower level courses, the upper level classes (TECH 4330 and TECH 4310) permitted students to experience the entire product cycle through the avenue of laboratory projects. Thus, our curriculum development efforts focused on reengineering these existing courses to incorporate the aforesaid innovations.

Curriculum development in turn led to the choice of capital equipment. Accordingly, the following equipment was deemed essential for project implementation:

[1] Vedaraman Sriraman, Department of Technology, Southwest Texas State University, 601 University Drive, San Marcos, TX 78666, vs04@swt.edu

- Stratasys FDM 3000 Rapid Prototyping Machine.
- Investment Casting Equipment
- Mini-Jector 45 Injection Molding Machine.

The equipment sought through grant funding was complemented by other equipment and facilities that were already available and on hand. These included:

- CAE laboratory with 16 engineering workstations that were loaded with Pro/ENGINEER (for solid modeling), Algor (for Finite Element Analysis) and AFS Solid (for solidification modeling).
- Helisys LOM 1015 RP machine.
- Foundry and Heat Treatment laboratory with general sand casting capabilities.
- Automated Machining laboratory with a three-axis Bridgeport machining center and a Browne and Sharpe coordinate measuring machine (CMM).

The grant was funded in Fall 1999 and lasted until Summer 2001.

DETAILS OF PROJECT IMPLEMENTATION

For purposes of convenience, this section is detailed through the medium of one of three courses previously cited, i.e. TECH 4330, to explain how curriculum integration was achieved.

One of the areas in which rapid prototyping and time compression technologies have had a major impact on product lead-time is in metal casting. With the advent of CAD, CAE, RP, and common format file transfer (such as the STL format), it has become very easy to take advantage of many manufacturing engineering applications using a single data base. Just 8 or 10 years ago, castings were typically produced using hand made or hand machined patterns. In just a short time however, advancements in computer based technologies have totally redefined the rules for the metal casting industry.

Students who enroll in this course would have typically completed prior courses in CAD, materials science, quality assurance, RP and fundamentals of manufacturing processes. In this course, lecture and laboratory activities include castings design, heat preparation, spectrographic analysis, the relationship between heat chemistry, cooling rate and microstructure and all of the standard tests that are currently used to provide manufacturing engineering with the ASTM traceability for cast products.

Towards the conclusion of the semester, students are assigned a capstone project wherein they design, analyze, optimize and manufacture a cast part. Students use CAD and CAE tools to design and optimize the castings. RP is used to support manufacturability analysis and generate the pattern/tooling. Students have to deal with issues such as recycling of the casting and molding materials. Thus, they have an opportunity to experience all aspects of the product cycle.

CASE STUDY

An example of a senior design project involved re-engineering a brake drum for a forklift (see figure 1). The brake drum was broken and neither spare parts nor engineering drawings were available. Measurements from the old brake drum were used to create a solid model of the same in Pro/ENGINEER (see figure 2). Students selected a material for the brake drum based on functionability, castability, machinability, and cost.

FIGURE. 1
BROKEN BRAKEDRUM

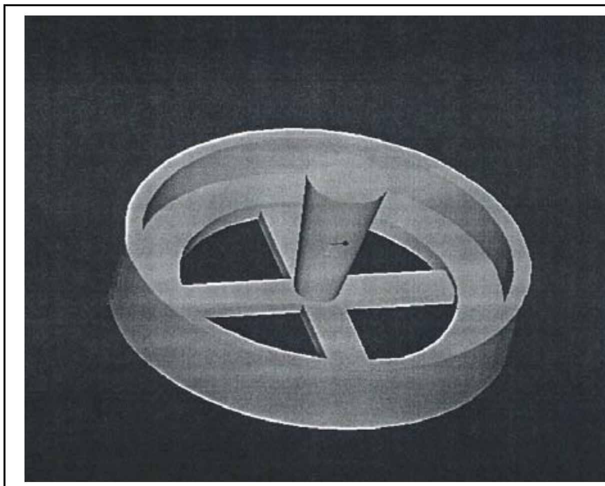

FIGURE. 2
PARAMETRIC SOLID MODEL

Next, a stereolithography (STL) file of the part was generated. This file was used as an input to the RP process (Stratasys FDM machine, see figure 3). Once the prototype was developed, it was evaluated for form, fitness, draft angles, machining allowances and shrinkage allowances.

Subsequently the rigging system was determined, modeled in CAD, and assembled on to the casting. This model was used as an input to AFS Solid to perform a solidification analysis. Upon completion of this analysis, students used outputs such as temperature distribution, solidification time, critical fraction solid, porosity and hot spots to refine the rigging system.

FIGURE. 3
STRATASYS FDM MACHINE

The next step involved creating a match plate model in Pro/ENGINEER for the brake drum (see figure 4). An STL version of this model was input to the Helisys LOM RP machine, so as to produce the appropriate tooling.

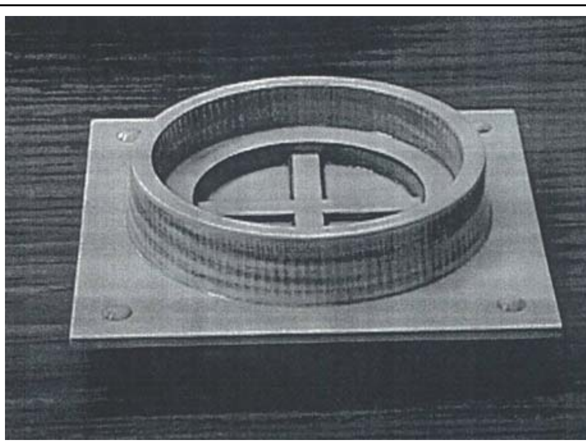

FIGURE. 4
RAPID PROTOTYPE OF TOOLING

Lastly, the match plate was used in the Metal Casting laboratory to make molds in sand. The mold was poured. Upon solidification the cast part was retrieved. The final product was obtained by machining the cast product in the Material Removal laboratory. At this point in time, students assisted the instructor in recycling the molding sand and excess metal.

CONCLUSIONS

Student reactions to the capstone design experience have been very favorable. Many students are able to assemble the pieces of knowledge that they had learned in specific courses towards the solution of a common engineering problem. Thus, a key result of our grant undertaking was that the laboratory project helps students see the "big picture". As engineering and technology knowledge base keeps growing, a significant dilemma confronts engineering educators. On the one hand dedicated courses are required to teach specific bodies of knowledge such as material science, processes, controls, design, etc., while on the other it is important that students "see" the interconnectivity between these specific bodies of knowledge. This paper outlined one such approach to curriculum integration.

ACKNOWLEDGEMENT

ON THE USE OF NUMERICAL MODELS AS SUPPORT FOR SOLVING ENVIRONMENTAL PROBLEMS IN COASTAL AREAS

Joseph Harari[1] *and Ricardo de Camargo*[2]

Abstract — *Numerical models have been largely used for studying environmental systems – atmosphere, oceans, continents, polar areas, etc. These models solve the differential equations that describe the spatial and temporal variabilities of these systems, allowing simulations, hindcasts and even forecasts Coastal areas are particularly affected by environmental problems related to sea - air interactions and human activities: coastal erosion, water pollution, flooding of flat areas, etc. Numerical models may help engineering solving these problems by giving information on the behavior of the systems. The numerical models commonly used are: atmospheric models (for simulating winds and meteorological systems), wave models (wind generated sea surface waves), hydrodynamic models (ocean currents, sea surface levels and properties of sea water), and dispersion models (distributions of particles, substances or pollutants, in the atmosphere and oceans). Environmental issues and the use of related numerical models are presented, for study cases in the Southeastern Brazilian coastal region.*

Index Terms — *Numerical models, Atmospheric systems, surface waves, ocean currents, dispersion in the air and sea.*

INTRODUCTION

Numerical modeling is the technique that makes use of mathematical and computational methods to represent and analyze physical events. In other words, numerical modeling simply takes the equations that describe a system and use them to simulate the changes in the system. With the right equations and proper mathematical techniques, scientists can use numbers and variables to create rather accurate portrayals of atmospheric and oceanic processes. The equations are solved for specific variables, which can be used in visualizations of how the atmosphere and ocean change with time.

Atmospheric and ocean dynamics are represented in the models by equations of conservation (of mass, momentum, heat, water vapor or salt, etc…), modified according to the spatial and temporal scales involved. Solutions to the equations are found through numerical methods (finite differences, finite elements, etc …).

Models may be used for hindcasts and forecasts, provided the necessary initial and boundary conditions to the equations.

A sequence of numerical models is being implemented by:

- Group of Oceanic Modeling of the Institute of Astronomy, Geophysics and Atmospheric Sciences of Sao Paulo University (Grupo de Modelagem Oceânica – GMOC, do Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo - IAGUSP) and
- Laboratory of Hydrodynamical Numerical Simulations and Predictions of the Institute of Oceanography of Sao Paulo University (Laboratório de Simulação e Previsão Numérica Hidrodinâmica – LABSIP, do Instituto Oceanográfico da Universidade de São Paulo - IOUSP).

The main objective of the models is to represent the most important physical aspects in the South Atlantic Ocean, with emphasis on the Eastern part of the Brazilian coast and continental shelves.

METHODOLOGY

Initially, the results of global meteorological operational models are obtained, as given by the Center of Weather Prediction and Climatic Studies (Centro de Previsão do Tempo e Estudos Climáticos – CPTEC, Brasil) and the National Climate and Environmental Prediction – NCEP, USA; their results for the South Atlantic (every 6 hours, with horizontal resolution between 200 and 250 km) are processed, graphically displayed and subsequently assimilated into a mesoscale meteorological model, the Regional Atmospheric Modeling System - RAMS (Cotton et al., 1982; Pielke et al., 1992); that allows the attainment of details of the surface winds and other variables of interest (with horizontal resolution of 32 Km, at every hour).

The surface winds are then transferred to the WaveWatch-III - WW3 (Tolman, 1991, 1999), a numerical model of third generation that represents the sea state (sea surface waves), with a horizontal resolution of 1/12°. This model solves the equation for wave action spectral density, assuming that the environment (bottom topography, currents) and wave field present variabilities in space and time with scales much larger than the scales of a single wave. The model equations include refraction and straining of the wave field due to mean depth and currents, growing or decay of waves due to

[1] Joseph Harari – Institute of Oceanography of the University of Sao Paulo, Sao Paulo, Brazil, joharari@usp.br
[2] Ricardo de Camargo - University of Astronomy, Geophysics and Atmospheric Sciences, Sao Paulo, Brazil, ricamarg@model.iag.usp.br

winds, dissipation and bottom friction. The wave model is valid for ocean depths bigger than 40 – 50 meters.

The sea surface winds are also used as input to ocean circulation models, as the Princeton Ocean Model - POM (Blumberg & Mellor, 1987), in order to evaluate the ocean currents, surface levels and sea water properties of temperature, salinity and density (Harari, Camargo & Cacciari, 2000).

Finally, the ocean currents are used to estimate the dispersion of properties, pollutants and tracers in coastal areas, through the solution of the advection – diffusion – decay equation or, alternatively, through the Lagrangean tracking and random walk of particles (Harari & Gordon, 2001).

The operational predictions regularly performed by GMOC and LABSIP may be acessed in www.surge.iag.usp.br .

RESULTS

A selection of results will be presented, relative to the four kinds of model above cited.

Figure 1 shows *CPTEC* large scale analyzed fields for the period of 13 to 16 July 2000, relative to a frontal situation in the 13th and a new cyclone formation in the 15th and 16th.

A model prediction of sea surface waves is presented on Figure 2, giving the elevations and directions of propagation.

Simulations of the mean sea surface level in the harbor of Santos (Brazil) through a hydrodynamical numerical model of the Southwestern Atlantic (POM) are presented on Figure 3, considering inputs given by a large scale atmospheric model (CPTEC) and a regional one (RAMS); this figure also shows the good agreement between these numerical simulations (with horizontal spacing ranging from 7800 to 9100 m) and observations (which tidal oscillations were filtered out).

Figure 4 shows a prediction of sea surface currents in the oceanic area off the Southeastern Brazilian shelf, with a horizontal resolution of 1/12° in longitude and latitude. In this case, the model was forced by surface winds (predicted by the large scale atmospheric model of NCAR), density effects (with climatological values of temperature and salinity), tides and mean sea level at the open lateral boundaries (given by a global model of tides and climatological values of dynamic depth, respectively).

Simulations of the dispersion of continuous substances and particles are presented on Figure 5, for the coastal area of Santos, under the effects of tides and NE winds.

CONCLUSIONS

This publication presents recent developments in operational and theoretical numerical models which can be useful for practical applications in several human activities, such as navigation, fishing, coastal protection, prediction of severe meteorological conditions and coastal flooding, water quality control, air and sea pollution prevention, among many others.

For future research, coupling of these physical models to biological / geological ones and making available the model results to authorities and policy makers is recommended.

ACKNOWLEDGMENT

The authors are grateful to the Institute of Oceanography of the University of Sao Paulo (Instituto Oceanográfico da Universidade de São Paulo – IOUSP) and Institute of Astronomy, Geophysics and Atmospheric Sciences of the University of Sao Paulo (Instituto de Astronomia, Geofísica e Ciências Atmosféricas da Universidade de São Paulo – IAGUSP) for their support in the modeling researches and operational implementations.

ENSINANDO ORGANIZAÇÃO DE COMPUTADORES E SISTEMAS DIGITAIS USANDO HARDWARE RECONFIGURÁVEL DE BAIXO CUSTO

Roberto Medeiros de Faria[1], Elmar Uwe Kurt Melcher[2] e Maria de Fátima Queiroz Vieira Turnell[3]

Abstract — *Often some form of simulation is used in computer science classes in order to demonstrate aspects of computer organization in laboratory experiments. Our experience shows that it is very difficult for a student to grasp how a computer really works from simulation. In electrical engineering classes, sometimes discrete TTL logic devices are connected manually to form more complex digital circuits. However, it is very difficult to build even a very simple processor using this approach because most of the time is lost searching for bad electrical connections.*
This paper presents a low cost FPGA (Field Programmable Gate Array) based kit specifically developed for teaching hardware topics. Starting with a very simple circuit that may use only a flip-flop and an inverter, students may build a finite state machine and finally implement a simplified processor. Based on our experience during 5 semesters we can see that the practical knowledge is acquired more thoroughly using our method.

Index Terms — ensino de tópicos de hardware, arquitetura de computadores, organização de computadores, sistemas digitais, FPGA.

INTRODUÇÃO

É comum encontrar os cursos de arquitetura e organização de computadores ou sistemas digitais utilizando-se de alguma forma de simulação para realizar suas práticas de laboratório. Isto ocorre por diversas razões, que vão desde a facilidade de obtenção de software para este fim até a dificuldade de aquisição do material necessário e específico na montagem de um laboratório hardware, pelos altos custos envolvidos. Esta prática distancia muito o aluno da realidade concreta dos elementos de construção de um computador, impedindo que o mesmo atinja completamente os objetivos previstos para estes cursos. Para vencer este problema, a idéia é colocar nas mãos do aluno componentes de hardware e até um processador real com o qual ele possa experimentar à vontade, dominando assim o funcionamento e os elementos de construção de computadores.

O presente trabalho mostra uma alternativa de baixo custo para a instalação de laboratórios de hardware, para cursos de graduação em computação e engenharia elétrica, a partir de laboratórios de PC's (computadores pessoais), normalmente já existentes, a um baixo custo financeiro adicional. A solução mais barata que se tem no mercado é adicionar a um PC uma placa de expansão construída a partir de um FPGA (*Field Programable Gate Array* – dispositivo de hardware reconfigurável). Porém, mesmo assim, as placas deste tipo disponíveis no mercado são adquiridas a um custo ainda muito alto. Outra dificuldade, também, é que estas placas, via de regra, não foram projetadas para ensino e sim para demonstração de funcionamento de um FPGA ou, ainda, para desenvolvimento e teste de hardware específico, construído sobre um FPGA. Assim, estas placas não apresentam uma interface adequada que dê ao aluno uma visualização simples e efetiva do funcionamento do hardware construído.

A PEAC (Placa para Ensino de Arquitetura de Computadores), aqui descrita, se mostra como uma alternativa de baixo custo para equipar laboratórios de hardware, apresentando também uma interface que traz facilidades efetivas para o domínio, por parte do aluno, do projeto, construção e funcionamento de sistemas digitais modernos.

O ENSINO DE TÓPICOS DE HARDWARE E SEUS OBJETIVOS

Mostra-se a necessidade de ensino de tópicos de hardware de computação preponderantemente nos cursos superiores de computação e engenharia elétrica. Os objetivos do ensino de tópicos de hardware para essas duas áreas do conhecimento diferem principalmente na ênfase maior que é dada ao aprendizado de como projetar e construir computadores em ciência da computação, enquanto, em engenharia elétrica, a ênfase se dá na construção de sistemas digitais em geral. No mais, as disciplinas de tópicos de hardware para os cursos de computação e engenharia elétrica têm objetivos semelhantes.

De modo geral, as disciplinas de hardware de um curso de computação devem mostrar ao aluno a organização e a arquitetura de computadores, suas unidades funcionais e sua estrutura em níveis – os computadores modernos são organizados em camadas onde cada uma funciona como uma máquina virtual.

Também é importante mostrar ao aluno o funcionamento interno detalhado do processador, pois este, dentre os componentes principais do computador, é o que mais concentra funções, controlando os demais componentes e executando efetivamente as instruções.

[1] Roberto Medeiros de Faria, Elmar Uwe Kurt Melcher e Maria de Fátima Queiroz Vieira Turnell, Universidade Federal de Campina Grande, Av. Aprígio Veloso S/N, Bodocongó, 58109-970, Campina Grande, PB, Brasil, {rfaria@dsc, elmar@dsc, fatima@dee}.ufcg.edu.br

Pela natureza funcional do processador, é importante também mostrar ao aluno suas relações com as demais unidades funcionais do computador, evidenciando a distinção entre os caminhos por onde transitam os dados e como se dá a comunicação de controle, possibilitando assim ao aluno distinguir entre bloco de dados e bloco de controle de um computador, analisando os aspectos funcionais de composição e de construção.

Como o computador é na realidade composto de uma parte de hardware e outra parte de software, é muito importante dar ao aluno o conhecimento sobre como funciona a interação direta entre estas duas partes do computador (software e hardware), levando em conta que a fronteira que separa estas partes não é estabelecida de forma definitiva e varia de acordo com a tecnologia de construção empregada.

Vale ressaltar aqui que, quando o objetivo for aprender a projetar e a construir computadores, é fundamental que o aluno tenha condição de conhecer o suficiente para escolher a tecnologia que dará a melhor solução a cada projeto específico. Isto implica ter que experimentar e avaliar os vários modelos de solução disponíveis no mercado.

A experiência com o uso da placa PEAC, que se desenvolveu no Curso de Engenharia Elétrica da Universidade Federal de Campina Grande, foi no âmbito da disciplina Arquitetura de Sistemas Digitais. Esta disciplina tem como objetivo, além de introduzir os fundamentos da arquitetura destes sistemas, dar formação ao aluno em diferentes técnicas de projeto de sistemas digitais. Os conceitos são apresentados a partir do projeto de um computador didático, capaz de realizar cinco instruções, construído a partir de circuitos lógicos simples tais como contadores, registradores e um circuito somador [1].

Ao longo dos semestres em que a disciplina vem sendo lecionada, os alunos realizam experimentos durante os quais esta máquina é montada e testada. O projeto desta máquina permite ao aluno concretizar os conceitos apresentados na disciplina e conectá-los diretamente com os conhecimentos adquiridos na disciplina que lhe é pré-requisito – Circuitos Lógicos.

O Ensino de Tópicos de Hardware Utilizando Componentes Discretos

Construir computadores e sistemas digitais complexos a partir de componentes discretos de hardware é factível, não, porém, quando estes componentes mais simples e elementares são transístores. Tannenbaum, em seu livro sobre organização de computadores [4], escreve que embora o aluno estivesse "... apto a adquirir um saco cheio de transistores para construir o subconjunto da máquina JVM. Os estudantes que conseguirem concluir esta tarefa com sucesso devem receber a nota máxima na matéria e a recomendação de realizar um exame psicológico completo.".

Outra maneira de implementar um processador a partir de componentes discretos seria utilizar tecnologia TTL. Estima-se a necessidade de 50 componentes TTL para implementar todas as práticas de laboratório para um processador deste porte. Esta solução tem algumas dificuldades que devem ser analisadas. Se o circuito for implementado em placa de circuito impresso, em que os componentes são soldados, estes componentes não poderão ser reutilizados e as diferentes práticas laboratoriais exigirão placas específicas de circuito impresso, elevando assim o custo financeiro para a implementação do laboratório de hardware. A solução mais flexível, neste caso, seria a utilização de *protoboard* para a montagem do circuito. Porém, neste tipo de montagem, aparecem muitos problemas de falhas nas conexões elétricas e então, a maior parte do tempo do aluno aplicado nas experiências fica sendo utilizada na eliminação destas falhas.

O Ensino de Tópicos de Hardware com Simulação

É comum as disciplinas que ensinam tópicos de hardware fazerem uso somente de simuladores para ensinar aos alunos os conhecimentos necessários para cumprir os objetivos discutidos anteriormente. Existem várias razões para que a utilização de simulação de hardware seja tão largamente utilizada nestas disciplinas. A razão preponderante é o alto custo do hardware específico necessário em contrapartida com a utilização de laboratórios de computadores pessoais (PC's) utilizando software de simulação. Normalmente, as escolas já possuem seus laboratórios de PC's e os investimentos se restringem à aquisição do software, muitas vezes sem custo por ser de domínio público ou *freeware*. Por exemplo, há autores de livros didáticos sobre arquitetura e organização de computadores que indicam em seus livros o uso de ferramentas de simulação para execução de seus exercícios e práticas [2][3][4].

No seu conhecido livro "*Arquitetura e Organização de Computadores*" [3], Stallings defende o uso da simulação, afirmando que ela é vantajosa, tanto na pesquisa como para fins educacionais, pois "é mais fácil de mudar os vários elementos da organização..." e "...fornece diversas estatísticas detalhadas de desempenho...".

Diante das dificuldades de implementação de um processador, mesmo acadêmico, em hardware e da facilidade sedutora da implementação através de simulação por software, abre-se mão da qualidade do aprendizado, impedindo o aluno de fazer uso de um equipamento de hardware real e concreto em suas experiências laboratoriais.

Existem ainda situações em que a simulação não consegue espelhar a realidade, no caso, por exemplo, de conflito no barramento de dados com a RAM que na prática, eleva o nível da corrente, levando a uma situação de falha elétrica.

Na disciplina Arquitetura de Sistemas Digitais, como parte de uma estratégia que previa a apresentação de outras técnicas de projeto, foi introduzido o conceito de simulação de uma descrição do circuito a nível esquemático. O grupo de alunos, além de montar o protótipo do projeto original, foi solicitado a fazer modificações neste projeto, desta feita através da simulação do comportamento da máquina modificada. Esta etapa do aprendizado permitiu aos alunos experimentar diferentes arquiteturas resultantes de modificações no conjunto de instruções e modos de endereçamento na nova versão da máquina didática.

A possibilidade de modificar o projeto original se mostrou decisiva no processo de aprendizado. Não apenas aumentou a motivação dos alunos, mas acima de tudo facilitou a apreensão dos conceitos abordados na disciplina.

Como etapa subseqüente nesta estratégia de ensino das técnicas de projeto, foi introduzido o conceito de projeto em Linguagens de Descrição de Hardware – HDL. Neste ponto do curso, foram enfatizadas a complexidade do projeto de sistemas digitais e a necessidade de adequar a técnica de projeto.

O Ensino de Tópicos de Hardware Utilizando FPGA

Como já foi dito, a solução apresentada aqui é uma placa de hardware reconfigurável que faz uso da tecnologia de FPGA. O FPGA é um componente programável composto de milhares de portas lógicas que permitem ser configuradas de modo a implementar um circuito lógico qualquer. Melhor ainda, esta configuração pode ser refeita indefinidas vezes, de modo que o mesmo componente FPGA pode funcionar como um circuito lógico diferente a cada reconfiguração. Isto possibilita que uma mesma placa seja reconfigurada para dar suporte às várias experiências que são realizadas no laboratório. O fato de só utilizarmos uma única placa de circuito eletrônico vem contribuir para a redução do custo adicional com hardware específico.

A construção do hardware baseado em FPGA traz consigo as vantagens defendidas por Stallings [3] para o uso da simulação, ou seja, com o FPGA torna-se fácil modificar os vários elementos da organização, e dispositivos para fornecimento de estatísticas de desempenho podem ser inseridos no próprio hardware – vantagem maior.

Descrição da PEAC

A PEAC, placa de hardware de baixo custo, foi projetada para dar suporte às experiências dos alunos em toda a extensão dos cursos de tópicos de hardware, pois, por ser reconfigurável, permite experiências envolvendo apenas *flip-flops* e inversores, como exemplo de experimentos mais elementares, e pode também ser utilizada para implementação em hardware de um processador completo.

A placa tem como componente principal um FPGA EPF10K20RC208-4 da família FLEX de fabricação da Altera, com 20 mil portas lógicas equivalentes. Encontram-se também na placa 2 memórias RAM de 16 Kbytes que trabalham em paralelo para permitir o endereçamento de 16K palavras de 16 bits. Um oscilador de 2,5 kHz foi introduzido na placa para geração de sinal de *clock*.

Além dos componentes já citados, a placa possui alguns outros que são utilizados na interface com o usuário. Para este fim, a placa possui 4 bancos de 16 *leds* que são utilizados para a visualização de conteúdos de registradores e palavras de memória. Adicionalmente, encontramos um banco de 2 *leds* que é utilizado para visualização dos estados e controle da RAM (*write enable* e *output enable*). Por último, 1 *led* adicional permite a visualização do sinal de *clock*. Uma chave de onda com 11 posições foi colocada na placa para possibilitar a mudança da funcionalidade dos bancos de *leds*. Uma chave bipolar, incorporada ao circuito, permite gerar manualmente o sinal de *clock*. Também foram adicionados à placa, para aumentar a possibilidade do usuário interagir com a mesma, 4 bancos de 8 chaves liga-desliga do tipo *DIP-switch* que são utilizadas para configuração de funções de controle. Importante lembrar que, por estarem ligados diretamente aos pinos do FPGA, pode-se, se for necessário, reconfigurar toda a funcionalidade dos *leds*, da chave de onda, das chaves liga-desliga e da chave bipolar.

Um conector de 34 pinos é ligado diretamente ao mesmo número de pinos do FPGA, criando uma interface aberta, totalmente configurável para conexão com dispositivos de entrada ou saída, com outro circuito de expansão, ou ainda, com outra placa semelhante.

A placa funciona com três modos de *clock*: gerado manualmente, gerado diretamente pelo oscilador e gerado pelo oscilador com divisor de freqüência.

Para proteção de sobrecarga e para permitir evidenciar a ocorrência de conflitos no barramento de dados com a RAM, a placa possui um fusível eletrônico que corta sua alimentação, tanto no caso em que a corrente eleva-se a níveis danosos, quanto quando a tensão de alimentação supera 5 volts, protegendo assim todos os componentes do circuito.

Com o apoio do Programa Universitário da Altera (fabricante do FPGA da placa), representada no Brasil pela PI Componentes, em São Paulo, a PEAC pôde ser fabricada ao custo de aproximadamente US$ 80.

PEAC versus Outras Placas Semelhantes

Analisamos alguns aspectos importantes para placas de hardware reconfigurável que se prestariam para ensino. Os aspectos levados em consideração foram: custo, interface com o usuário e memória RAM. Entre 34 placas pesquisadas [5], placas estas que serviriam para o propósito de ensino e que fazem uso de FPGA, nenhuma contém recursos de visualização (*leds*) para mais do que 32 bits, nenhuma contém mais do que 20 chaves para acionamento e nenhuma custa menos do que US$129. No entanto, todas as placas pesquisadas, que possuem memória RAM, têm capacidade igual ou maior que 16 KB.

Comparando a placa PEAC com as placas pesquisadas, se torna evidente que ela é mais adequada para fins de ensino de tópicos de hardware digital a um custo menor.

METODOLOGIAS DE UTILIZAÇÃO DA PEAC

Na disciplina Arquitetura de Sistemas Digitais, o aluno é apresentado a um ambiente de suporte ao desenvolvimento de projetos em HDL e aos recursos oferecidos pela PEAC. O aluno, então, inicia o desenvolvimento de um projeto em equipe, que consiste na definição comportamental de uma versão modificada do computador didático.

No laboratório, a equipe realiza uma aula introdutória ao ambiente de desenvolvimento, e ao uso da placa. Após o término dos projetos, as equipes apresentam os resultados de cada projeto na forma de seminário. Uma vez que os projetos são agrupados em três categorias, durante a apresentação os alunos podem comparar e discutir as soluções adotadas.

Na disciplina Arquitetura e Organização de Computadores, para não sobrecarregar o aluno logo no início, são dadas práticas introdutórias e, em seguida, a construção de um processador é verificada em quatro etapas:

1) Construção de um pisca-pisca (divisor de freqüência) usando componentes TTL;
2) Verificação do funcionamento do pisca-pisca implementado na PEAC;
3) Verificação do funcionamento de banco de registradores e barramento interno;
4) (3) + ULA (Unidade Lógica e Aritmética);
5) (4) + interface com memória RAM;
6) (5) + ROM de microcódigo (processador completo);
7) Implementação, pelos alunos, de novas funcionalidades do processador.

Assim, começa-se com a verificação de um circuito muito simples no primeiro contato com a placa até chegar a modificar o processador Java completo [4].

RESULTADOS COM A UTILIZAÇÃO DA PEAC

A partir destas experiências, foi constatado que além do aprendizado ter sido positivamente influenciado, os alunos tiveram a oportunidade de exercitar conceitos que de outro modo seria inviável, uma vez que a construção de protótipos, em particular, demanda recursos de hardware nem sempre disponíveis. Constatou-se, também, que houve flexibilização para alterações em projetos, rapidez nas modificações introduzidas e redução nos custos de infraestrutura necessários ao ensino dos conceitos das disciplinas.

CONCLUSÕES

A tecnologia de FPGA oferece grandes possibilidades para fazer o ensino de arquitetura, organização de computadores e eletrônica digital mais acessível, mais efetivo e mais empolgante.

O uso da placa PEAC leva a uma metodologia de ensino que possibilita ao aluno iniciante desenvolver suas experiências na medida em que os conceitos teóricos estejam sendo vistos, ou seja, o aluno pode começar construindo elementos mais simples e evoluir para construções de sistemas mais complexos, até chegar à construção de um processador completo. As experiências podem começar analisando o funcionamento de um *flip-flop* e um inversor, passando por uma máquina de estados finitos, de forma que, no final, ele tenha construído um processador integralmente.

Pela nossa experiência com este recurso, podemos afirmar que, quando os conceitos são fixados através das experiências com elementos reais e palpáveis, a aprendizagem se dá de forma muito mais eficiente e que o aluno se sente muito mais seguro na aquisição do conhecimento. Por outro lado, o emprego de um dispositivo lógico programável libera o aluno de dificuldades operacionais de equipamentos antigos, como por exemplo, o citado *protoboard*.

ENERGY ENGINEERING MANAGEMENT CURRICULUMS FOR ACADEMIA AND INDUSTRIES IN DEVELOPING COUNTRIES

Athula Kulatunga[1]

Abstract — *It is extremely rare to find employees with energy management skills or other required background information within an organization at the start of an energy management program. This paper presents major skills and subordinate skills required by personnel involved in the energy management process. A separate subordinate skill analysis is presented for business managers and energy professionals. These subordinate skill analysis can be used to develop specific learning activities for each group. Energy education does not have to be delivered in a classroom environment. Day to day activities of each of the above group can be modified to teach skills and to enhance energy awareness. Finally, the outcome of an energy management program is subjected to the culture of the country and the organization in which the program is launched. Energy management programs must be tweaked to align with such variations so that the impact of the program is maximized.*

Index Terms — Academia, Curriculum, Energy Management, Industry.

INTRODUCTION

What is energy management? One definition is "the judicious and effective use of energy to maximize profits (minimize costs) and enhance competitive positions [1]." Definitions may vary from one society to another depending on how the environmental concerns and economic benefits are valued. Regardless, there are many common aspects to all energy management programs. They include: monitoring and reporting energy use; reducing energy consumption through improved efficiency; finding new ways to increase returns from energy investments; improving power quality; reducing brownouts and curtailments; finding new ways to include renewable energy; and enhancing distributed power generation.

For some countries, energy management is a new concept, while others have been doing it for many years. When national or provincial governments subsidize the utility companies, or when there are inadequate metering capabilities, the energy management efforts do not receive proper attention, or are very difficult to implement. On the other hand, it is unwise to pay whatever the utility provider bills a business, due to one's lack of understanding of energy consumption of that business. In some countries, the energy costs of a product may be higher than the labor costs for the same product. Understanding the energy consumptions of an organization by managers, engineers, and all facets of the work force benefits the entire business.

ENERGY MANAGEMENT PROGRAMS

How can businesses initiate energy management programs when there are limited knowledgeable workforces to implement them? This is a challenge faced by many countries. Until colleges and universities start offering course in energy areas, short courses involving specific areas can be developed to help businesses and industries. Energy management always involves a team effort. The team includes the management of an organization, a steering committee with a leader, an energy manager or engineer, who has a comprehensive understanding of the discipline, and many other employees in the organization.

The employees must be well educated, in order to enhance the management system; otherwise, even a very expensive program would do little to conserve energy. Skills required by the employees vary according to their involvement in the process. For example, the upper management needs enough information to make business decisions and future planning. The energy management steering committee also requires education in electrical and mechanical systems. All of the organizations workers should know the objectives of the program, and what their rolls are. Well-trained energy managers are always in great demand, and innovative methods are required to increase the awareness of energy management among each level of the organization.

SKILLS FOR MANAGERS

The commitment of management is essential for making any energy program successful. When the managers have some level of understanding related to terminology and methodology presented in an executive summary of an energy management proposal, the proposals that contain energy management opportunities (EMOs) may receive favorable judgment, and support.

Some EMOs require rescheduling of work hours, production line start-up times, and allocation of new resources. Managers must coordinate and approve such activities. Some EMOs focus on improving air quality, work environment, and safety. Managers should be aware of

[1] Athula Kulatunga, Ph. D., CEM, Department of Electrical and Computer Engineering Technology, Purdue University, West Lafayette, IN 47907, USA, nakulatunga@tech.purcue.edu

government regulations related to occupational safety and health. In fact, some energy management activities are started in an effort to avoid litigation associated with safety or health related issues. A manager with understanding of the above issues can make informed judgments about proposed EMOs.

Economic analysis and/or lifecycle costs of each proposed EMO is a must. No energy management initiative should start prior to this step. Just because there is little need for new material, retrofits, and equipment for certain energy saving efforts does not mean the effort is without a cost component. Whenever an existing system is changed, there is impact. Workers are involved in any adaptation, automatically adds labor costs. When an EMO needs capital investment, viability of the investment should be clear. Acquisition costs, utilization costs, and disposal costs of new equipment must also be taken in to consideration. Return of investments using simple payback period methods and others such as discounted cash flow, must be examined according to the accepted business practices within the organization.

One of the problems with energy use in commercial sector and industrial sector continues to be poor accountability. Since energy consumption is considered as a fixed cost in most industries, no one person is responsible for the energy use. One solution is to sub-meter each department within the industry, and give responsibility to each. In order to accomplish this, managers should be aware of the benefits and drawbacks of such actions, and instantiate programs to reward departments for improving their own energy efficiency.

In some developing countries, solar energy is abundant. Managers should be aware of such technologies and how they can be exploited or incorporated in to their systems. By organizing conferences and seminars related to specific types of technology, many companies can benefit. For example, an investigation or pilot study in the area of solar thermal collectors may benefit many industries that require hot water for their manufacturing processes. A study investigating the potentials of desiccant cooling may improve the efficiency of commercial buildings that require cooling in the summer or throughout the whole year.

Some countries have a national energy policy; others don't. Most countries do have some form of regulations related to energy use, brownout periods, and environmental protection. One country may have a higher priority for saving energy and preventing environmental pollution, instead of cost effective manufacturing processes. Whatever the focus is, managers should align their energy management efforts with the national priorities, because there may be government incentives and subsidiaries to facilitate those efforts.

Understanding of how energy is billed is another important skill managers should have. In some counties, energy bills are very simple, while in others it can be quite complex. A simple billing structure may include a fixed rate for every kWh of use, and a fixed rate for every kW of demand. A complex bill may include a ratchet clause, where the company has to pay a percentage of the maximum electrical demand for the previous eleven months too even if the facility exceeds an accepted level one time. Energy bills are not always accurate. Such knowledge can help managers decipher mistakes and save money for the organization.

In summary, a list of major skills needed by managers of an energy organization should include the following:

1. Understand energy terminologies, units, and conversions
2. Understand safety and health regulations
3. Understand impact of production rescheduling
4. Understand energy billing
5. Perform economic analysis and life cycle costing
6. Organize seminars and workshops for employees

To master these skills, a series of subordinate skills are required. Figure 1 below depicts the breakdown of those skills into a series of subordinate skills.

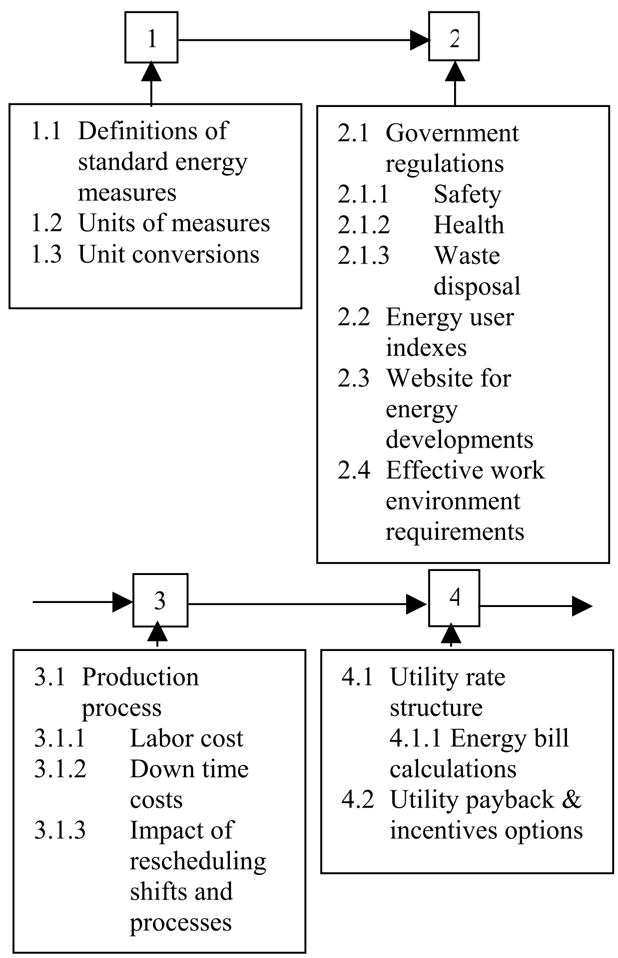

FIGURE. 1
SUBORDINATE SKILL ANALYSIS FOR MANAGEMENT

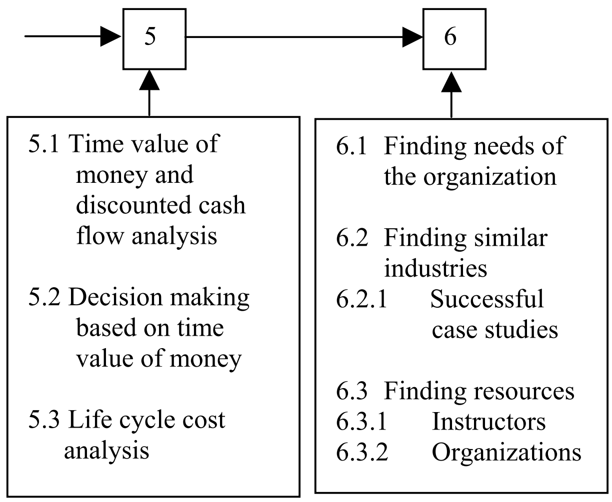

FIGURE. 1 (Continued)
SUBORDINATE SKILL ANALYSIS FOR MANAGEMENT

SKILL FOR ENERGY MANAGER OR ENGINEER

The energy manager is the key figure in all energy management initiatives. The person should have a technical background in the electrical and mechanical systems found in the organization. Those with technical abilities can be trained to become valuable energy manager.

An energy manager should be able to identify the energy-saving opportunities in a commercial or industrial facility. Energy may be purchased or generated locally. Energy may be consumed by lighting systems, a major portion of commercial facilities, air conditioning equipment, electric motors, steam generation, etc. By conducting specific energy audits energy managers finds energy saving opportunities.

An effective energy manager requires the following major skills:

1. Understand energy terminologies, units, and conversions
2. Locate and apply energy statistics
3. Understand energy use in commercial buildings
4. Understand energy use in industry
5. Perform economic analysis and life cycle costing
6. Perform energy audits
7. Integrate renewable energy sources

Each of the above major skill requires a series of subordinate skills. Figure 2 summarizes subordinate skill analysis for energy engineers or mangers [2].

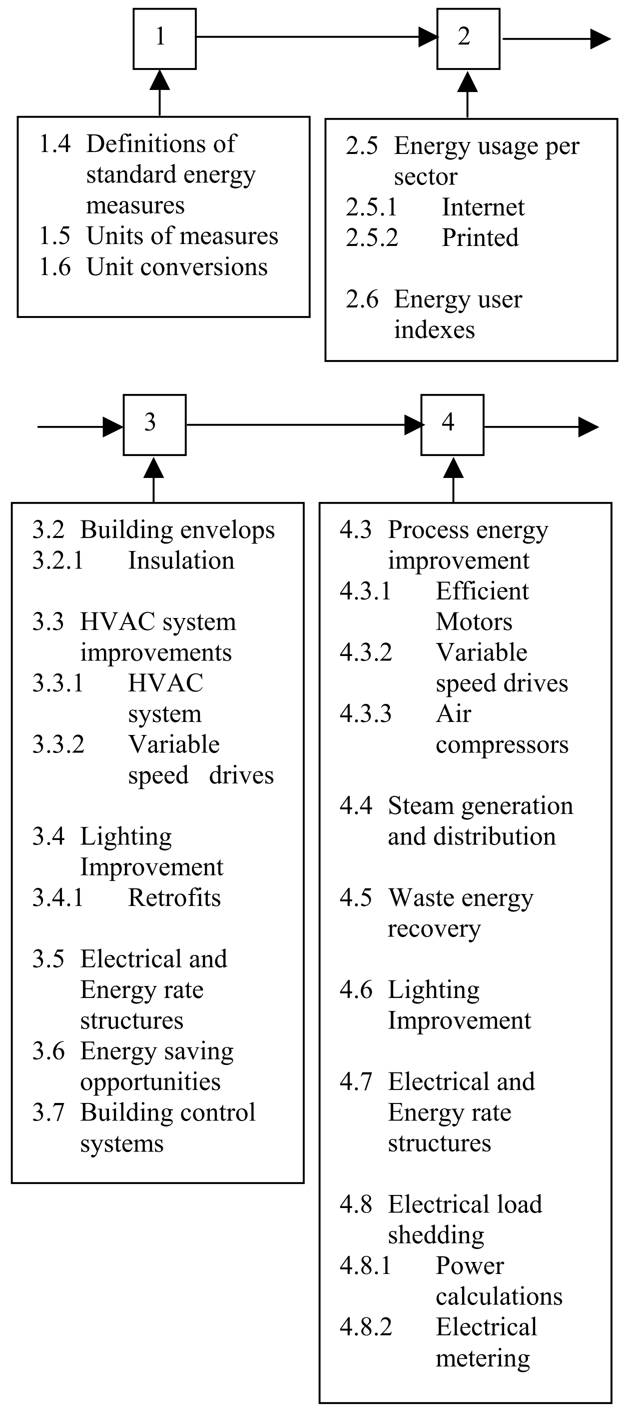

FIGURE. 2
SUBORDINATE SKILL ANALYSIS FOR ENRGY PROFESSIONALS

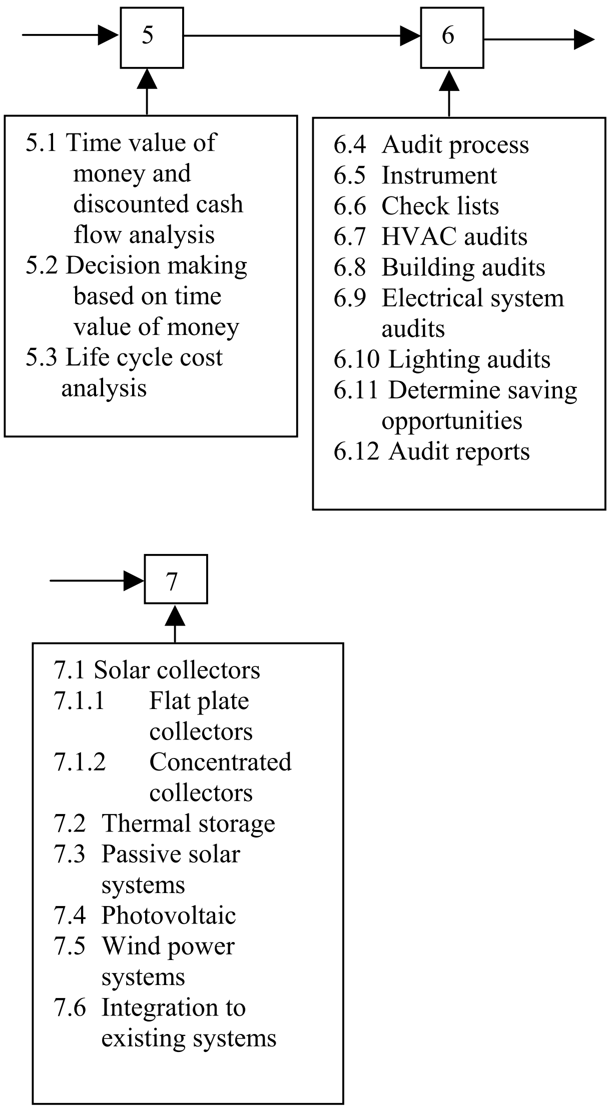

FIGURE. 2 (Continued)
SUBORDINATE SKILL ANALYSIS FOR ENRGY PROFESSIONALS

INFORMATION FOR EMPLOYEES

Employees in general can contribute energy saving efforts if they are well informed. They should know what the goals of their energy management efforts are, how it affects their work environment, and how they can contribute. Management should not wait until the final decisions are made to inform workers. Regular worker input is necessary, especially when energy audits are conducted. If the goal is to change existing lighting in a work area, worker opinion of current lighting and concerns about safety due to poor visibility are essential. Pamphlets describing energy initiatives can be distributed if a meeting of all employees cannot be called. Large posters spread across the facility can also remind the workers of ongoing efforts. It is also crucial to provide feedback to employees about the progress and success of these actions once they are implemented.

Some workers may need more detailed instructions than others. Operators who are in charge of a process of a system should be educated to evaluate and report any unexpected or unsuitable consequences due to changes that were made to accommodate EMOs. These workers should be aware of what the acceptable variations are. For example, if an across-the-line motor starter is replaced by a variable speed drive, the current meter will not indicate the inrush current that is inherited in typical induction motors. Simple efficiency changers such as which light should not be on during specific time of the day should be posted to keep workers informed.

OTHER ISSUES

The management of organizations and the energy managers in developing countries should also pay attention to metering methods and meters employed by their utility companies. Some countries have age-old power distribution system where little or no attention has been given to the metering aspects recently. Some meters are too old. Some meters records power consumption inaccurately when harmonics are present [3]. Certain new retrofit used to replace old ones with the expectation of saving energy may introduce harmonics to the power grid. It is paramount to verify the metering system or install their accurate meters before initiating energy management projects.

Finally, energy management is an applied field. One can learn some of these skills while conducting preliminary energy audits. Required checklists, record sheet, and actions to be taken are well documented and available to public through various organizations in the United States. For example, through US Department of Energy (DOE) and National Lighting Bureau in Washington, DC one can access different types of audit documents.

Linking Engineering Technology with a Business Administration Program

Raj R. Amireddy[1], Wes Grebski[2], Judith O'Donnell[3] and Lori Singer[4]

Abstract *— The paper describes the curriculum of the individualized option in the baccalaureate Business Administration program. The individualized option is a multidisciplinary curriculum which links the Mechanical Engineering Technology and Electrical Engineering Technology associate degree programs with the baccalaureate Bachelor of Science in Business degree program. Graduates from this program will be prepared for management positions in the manufacturing industry.*

Index Terms — About four, alphabetical order, key words or phrases, separated by commas (for suggestions Preparation of papers, camera-ready, two-column format, ICECE format).

INTRODUCTION

The competitive job market of the 21st century forces college graduates to seek and develop unique and rare skills. The acquisition of these skills is often the deciding factor in achieving employment goals. In a constantly changing work environment, these interdisciplinary skills are more important than ever before. As a result of this situation, professional societies and accrediting bodies encourage and support interdisciplinary projects in the curriculum.

CURRICULAR ISSUES

Penn State Hazleton offers traditional mechanical technology and electrical technology programs. These programs are ABET accredited and are offered in Hazleton at the associate degree level. The graduates of these programs can either seek employment or continue their education at the baccalaureate level. A majority of the students continue their education in the baccalaureate degree programs (Fig. 1).

Unfortunately, those baccalaureate degree options are not available at Penn State Hazleton. Depending on the choice of major, most students continue their education at the Capital College in Harrisburg, the Altoona College, or the Berks-Lehigh Valley College. Penn State Hazleton also offers associate and baccalaureate degree programs in business administration. Similar to the engineering technology students, business administration students who graduate with an associate degree can either enter the job market or continue their education in a baccalaureate degree program. In contrast to engineering technology, however, a baccalaureate degree program in business administration is available in Hazleton.

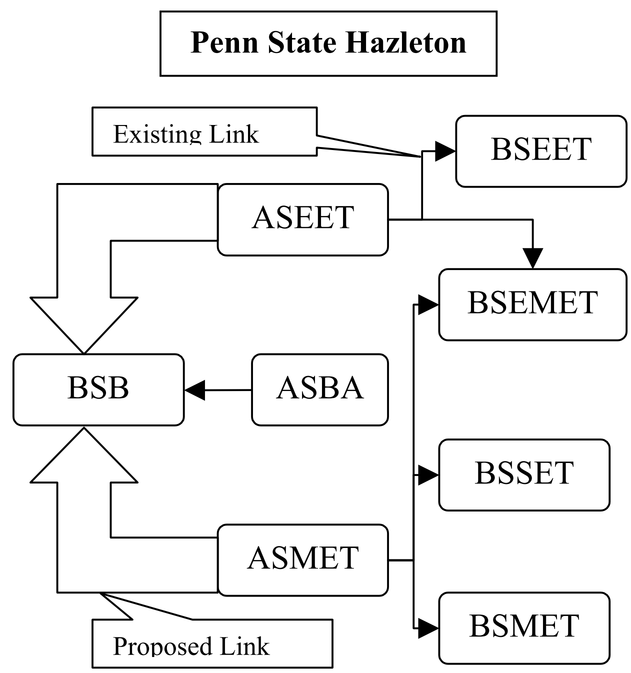

FIGURE 1
EXISTING AND PROPOSED LINKS

By linking these two programs, students at Hazleton in the Engineering Technology programs are afforded the opportunity to complete a baccalaureate degree and remain

[2] Wes Grebski, Associate Professor & Mechanical Engineering Program Coordinator, PSU Hazleton, 76 University Drive, Hazleton, PA 18202, USA, wxg3@psu.edu
[3] Judith O'Donnell, Women's Studies Instructor & Advising Center Coordinator, PSU Hazleton, 76 University Drive, Hazleton, PA 18202, USA, jso1@psu.edu
[4] Lori Singer, Business Instructor & Business Program Coordinator, PSU Hazleton, 76 University Drive, Hazleton, PA 18202, USA, lxs46@psu.edu

at Hazleton. In this two plus two design, Engineering Technology students complete their associate degree and then reenroll in the baccalaureate degree the following semester. The transition is virtually seamless and allows students to complete both the associate and the baccalaureate degrees in approximately nine semesters.

One might think that a conjunction of business concepts with engineering principles is hugely unlikely. The reality is that engineers may be some of the best resources to market and sell various product lines due to the fact that they have the ability to describe the reliability, functionality and needs for buying parts and/or products.

One of the most basic rules in business is the 80/20 Rule. This basically states that 20 percent of a firm's customers are responsible for generating 80 percent of a firm's revenue. Some experts believe that customer retention has a more powerful impact on profits than market share in terms of competitive position in the market place. Some basics of customer retention include: trust building, personal contact, proper installation and training, and seeking customer feedback by follow-up.

It is in the best interest of firms to employ and grow engineers with solid mechanical and/or electrical backgrounds who could communicate to consumers with a firm understanding of the product design and functionality, as well as an understanding of how the use of the product will impact their businesses. This is why the link between engineering technology and business concepts in education is so crucial.

In the 1999/2000 academic year, an agreement was reached between the engineering technology program and the business administration program. This agreement created an individualized option in the baccalaureate BSB program. This new individualized option allows ET graduates to enter into the BSB program at the junior level. This agreement created a very valuable and attractive option for associate degree ET graduates.

The curriculum developed for those individual options is shown in Fig. 2. During the first two years the students take engineering technology courses. Business related courses are taken by the students during the junior and senior years. Presently, a number of students are successfully pursuing this option. At the end of the 2003 spring semester, a number of engineering technology students will graduate with a BSB degree. The feedback received from the students who are pursuing this individual option is very positive. The Penn State Hazleton Industrial Advisory Committee supports the program.

The graduates from this individualized, interdisciplinary program will have the skills necessary to seek manufacturing management positions in industry. The multidisciplinary background of the graduates will allow them to work and communicate effectively with the engineering and technical staff. The graduates will also be able to work effectively with the marketing and accounting staffs as well as with financial institutions.

Since management styles have changed dramatically over the last few decades, with a team of directors leading organizations rather than one sole leader as was done in the past, it makes perfect sense to include individuals with quantitative abilities as one or more of the team members. Due to this current need in almost all businesses, it has become clear that quantitative thinkers need to understand communication and management styles to be effective and successful. Teams and groups now dominate in most work settings for decision making, whereas individual efforts were once hailed. Since business in general has become more complex, with innovative technology that is constantly changing and firms diversifying product and service lines of business so rapidly to stay competitive, it seems to follow logically that engineers should be an integral part of the upper echelon of individuals who lead an organization. Probabilistically speaking, to make engineers more successful, the event of business concepts and applications (call it Event A) is the perfect complement to the event of engineering talent (Event B). Given that these are the only two events in the sample space, the probability of Event A in union with Event B ($P(A \cup B)$) will be equal to $P(S)$, the probability of the sample space, which is a perfect number 1

CONCLUSIONS

The individualized option of the Bachelor of Science in Business program, which has been described, is expected to increase the enrollment in both that program and the engineering technology programs. Penn State Hazleton will survey graduates and employers after a significant number of graduates enter the workforce.

FUZZY LOGIC APPLIED TO INFORMATION RETRIEVAL SYSTEMS

Dulce Magalhães de Sá[1]

Abstract — *Information retrieval systems can be used in a variety of contexts. For example, these systems can be used to support business or learning environments and digital libraries. Information retrieval systems are a type of resources that allow to obtaining information for decision making. Some reasons for information retrieval problems are data structures issues, efficiency of interfaces, information organization, database management systems absence, quality of information and information systems not suitable for specific process use. As a form to reduce the number of problems in information retrieval, fuzzy applications can be used to detect partial needs of user queries and access information element. It also can be used to organize the system answers by ranking of importance to facilitate the user decision, because in fuzzy logic an information element can reside in more than one set of different degrees of similarity.*

Index Terms — *Digital Libraries, Fuzzy Logic, Information Organization, Information Retrieval Systems, Multimedia Applications, Retrieval Techniques.*

INTRODUCTION

One important topic for design and develop information retrieval systems is the data structure and organization of information contents. Data structure is data grouped by an organization method of simple data collections [1]. Between the possible types of data structures are records, sets or files.

The evolution of the Internet, particularly its Word Wide Web component, has created new opportunities and ways of application and analysis of information retrieval systems. One of the components of information retrieval systems is information itself that, in certain ways, has become a social and economical product.

One of the ways of organising information is by creating databases, developing applications and implementing database management systems [2]. Interactive databases in information retrieval systems are a critical component of the success of the system and, eventually, of the organisation that owns it, because they constitute a decision support tool.

INFORMATION RETRIEVAL ISSUES

Information retrieval is the ability of obtaining answers on information needs expressed to system in a language, usually a query language. Information retrieval systems are developed to provide efficient ways of search. Reference [3] defines information retrieval system as a system used to store items of information that need to be processed, searched, retrieved and disseminated to various user population.

The basic components of retrieval information systems are search formulation, search software, information storage environment and queries process [4]. This involves hardware for information storage and persons (searchers) that executes queries.

- *Searcher* - person who has information or information contents needs and then begins the search process. In a particular case, the searcher can be a mixed entity between any person who elaborates part of the initial search process and a software agent who limits the scope of the search [2]. The human search is mostly oriented by subjective processes. The software agent searcher transmits to system the subjective aspects of the human user through rules previous fixed. Software agents can interfere in other phases of search, such as structures of search formulation [5].
- *Search formulation* - a process that requires some decisions that concern to topics of search, information fonts or contents, design of search formulation and which resources should be used in search process.
- *Resources* - software to search in local mode, private networks or Internet [4].
- *Information storage* - an important aspect of retrieval information systems because it allows search across the data structures.
- *Retrieval items* - aspects to performing the way that the system answers to queries depends of its design and conception.

Retrieval techniques are methods or processes used by systems for extract information topics in a particular way. A classification of retrieval techniques [6] distinguish between exact and partial match techniques. Exact match, for example Boolean retrieval and string matching techniques, requires precise information contents concern to topics of search.

Partial match techniques are used to compare queries with information elements represented as sets of features or index terms. Its include techniques based on formal models of information retrieval as probabilistic model, based on the probabilities of relevance to the query or fuzzy set model.

BOOLEAN INFORMATION RETRIEVAL

Information retrieval systems normally accept Boolean expressions, based on logic operators, as queries. Logic

[1] Dulce Magalhães de Sá, ISEGI – Universidade Nova de Lisboa, Campus de Campolide, 1070-312 Lisboa, Portugal, dulce@isegi.unl.pt

operators provide to their subject elements (Boolean data type), operations of conjunction, disjunction and negation. Negation operations are processed as exclusion of particular elements in a set of various elements. Logic operators are AND, OR and NOT [7].

Logic operators are used to clarify search formulation in retrieval systems. Let A, B and C words (strings) of any search formulation [A AND B] provided as answer all records with A and also B.

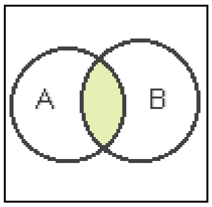

FIGURE 1
BOOLEAN OPERATION: [A AND B]

[A OR B] provided as answer all records whit A, all records with B, and also all records with A and B.

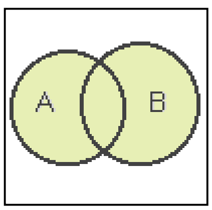

FIGURE 2
BOOLEAN OPERATION: A OR B

And [A AND B AND (NOT C)] provided as answer all records with A and B, but not those with of A and of B but not C.

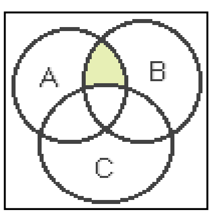

FIGURE 3
BOOLEAN OPERATION: A AND B AND (NOT C)

To obtain efficient results some design aspects must be considered for developing information retrieval systems. They must have a user-friendly search environment, including interfaces and data structures with Boolean type which supports logic operators [8].

However, Boolean information retrieval no ranking answer elements. The way that information contents are treated by retrieval systems and the way that it is presented as an answer to a query or request, are important factors to decision make process.

Difficulty to obtain answers to specific queries and access difficulties to found information contents or valid references to information needed are typical problems on information systems [9] and retrieval systems. A retrieval based on fuzzy set model provide searches with a decision rules to filtered information on databases and can be ranking answer elements to facilitate the decision make process.

FUZZY INFORMATION RETRIEVAL

Fuzzy logic is basically a multi-valued logic that allows intermediate values to be defined between usual valuations like 1/0, yes/no or true/false. It has been used initially in system theory to describe and implement uncertain notions and general concepts [10].

In fuzzy logic an information element can reside in more than one set of different degrees of similarity. Fuzzy relations represent a degree of presence or absence of association, interaction or interconnectedness between the information elements of two or more fuzzy sets.

One of the components of a fuzzy logic system is rules. These rules will be expressed as logic restrictions, in the forms of IF-THEN statements [11]. They are usually of a form similar to the following: *if x is low and y is high then z=medium*.

The area of information retrieval has also benefited from fuzzy logic methodology. Some fuzzy operations like union, intersection or complement can filter information elements with values between absolute true (1) and absolute false (0).

This provides a tool for natural language interfaces in retrieval systems and solution for some information retrieval problems. The software agent searcher that transmits to system the subjective aspects of the human user through rules previous fixed can be based in a fuzzy logic structure [2].

There already exist query systems that provide an ordering among the information items that more or less satisfy the request. The systems may allow for the presence or imprecise, uncertain or vague information in the system database.

One considers a system where the domain of each expression X (word or set of words) is represented as a function of a theme Y. If the expression X is associated to theme Y, X is relevant else X is irrelevant as retrieval item.

The grade of relevance is express for the weight of each X in a Y by numbers: 3 for must relevant, 2 to relevant and 1 to irrelevant. X is must relevant to theme Y if it is associated to weight 3, relevant if the weight is 2 and irrelevant for grade 1.

Weight 3 can be associated to a probability of X is include in Y, for example, between 1 and 0.75; for weight 2, if between 0.75 and 0.5; and for weight 1, from 0.5 to zero. This reduces retrieval items associated to theme Y because only consider "relevant" weights 3 and 2, supposing a rule which determine relevance as a probability of 0.5 as minimum.

CONCLUSION

Where information elements are stored in systems database, they can be classified by one of three weights, but this depends of the subjectivity of person who classified that. This process can be applied in simple and specific systems.

For large and complex systems is more reasonable that decision process depends of searcher. Thus, the retrieval system provides to searcher an optional theme Y for expression X gives by searcher.

System selects in information elements of database or in documents which Xi had weights 3 and 2 on Yi and retrieved them. Xi and Yi are any X and any Y respectively in each record on database or document (file) where X or Y exist.

System can be incremented, for example, by more variables like one second expression Z or more weights for relevance or other elements. This gives more complexity to system processing, but easiness to searcher person that use system and provide more efficient answers.

OBSTACLES ENCOUNTERED BY UNICAMP ENGINEERING PROFESSORS WHILE DEALING WITH DISTANCE TEACHING PROCESSES

Dilermando Piva Jr.[1], Mauro Sérgio Miskulin[2] Ricardo Luis deFreitas [3], Geraldo Gonçalves Jr. [4] and Rosana Giaretta Sguerra Miskulin. [5]

Abstract — *There is a clear growth in Web use by Universities, with the purpose of spreading online courses. However, online teaching is far from reaching its maximum potential. Several obstacles were pointed out as being the main cause for the deficiencies encountered during studies carried out in a number of countries. The causes for these problems were personal, technological, and institutional. This article has as its main objective, to take these main obstacles that were pointed out during the studies, and see how true they are within the Brazilian reality; specially in the technological area, taking the Engineering courses at State University of Campinas (Unicamp) as the basis, through research done with professors from different courses of this Institution.*

Index Terms — *Distance education, Engineering Education, Obstacles in distance learning, Engineering online courses.*

INTRODUCTION

The increase of Internet use as a way of improving communication means as well as the broadening of computer processing power, have favored the growth of distance learning through the web (online teaching). This has motivated Universities to re-think their practices and teaching policies, and to adopt online teaching programs.

The increases in the learning process quality, the maintenance of competitive advantage, and the improvement in the means of education access, were pointed out as the three main reasons for the set up of online courses according to studies done at the end of the last decade by Universities [1], [6] and [9].

However, the use of online teaching potential is far from reaching its maximum. A number of studies and researches done throughout the world indicate various obstacles, which were pointed out by professors. These obstacles were caused by personal, technological and institutional problems.

This article has as its main objective, to take the main obstacles identified in these studies and researches, and see how true they are within the Brazilian reality, especially in the technological area, taking into a basis the Engineering courses at State University of Campinas (UNICAMP), through researches done with professors at this Institution.

OBSTACLES FOR THE INTRODUCTION OF WEB BASED LEARNING – WORLD CONTEXT

A lot has been written about the importance and the value of the contextualized computer in the teaching/learning process. Glace and Smith [3] wrote about the gap that exists between the expected technological level and the one really used by professors. To obtain success in the integration of technology to teaching, we should not only rely upon the use and acceptance of technology by the students; but also, and on priority bases, rely upon its understanding and mass use by professors.

In the case of online teaching, studies have shown a number of obstacles (barriers) that block the effective use of technology by professors, causing a gap to appear between the expected and the real use of such technology.

Pajo and Wallace [10], based on research results done with Professors at the Business, Science and Education School at Massy University (New Zealand), pointed out as the main obstacles: 1) time required to learn how to use the technology; 2) time associated with the development and implementation of web based courses; and 3) time required to use online teaching environment as well as course monitoring (student feedback).

Aside from this first set of personal obstacles, the same authors point to another group that are imposed upon by the teaching Institutions, which they called organizational obstacles: inadequate technical support, the lack of institutional of recognition/importance of processes involving online teaching and insufficient available funds.

Already in 1995, James and Beattie [7] did a study on graduate education in Australia, which showed a slow evolution of options in his long distance teaching, whereas

main means of instruction was still written. According to the authors, a major use of online teaching has not yet been reached due to lack of academic pattern consensus, to bad results about other academic work, and the lack of technical support.

Specifically on the item academic work impact, the authors with the help of professors who were interviewed, identified the reasons that influenced this negative impact, and arrived at the three main (obstacles): 1) time required for managing the groups and other chores that go along online teaching (especially feedback to students), 2) a large amount of time required for the production of good quality learning material; 3) long distance teaching is just as rewarding, or less than through traditional teaching methods.

To enhance this hypothesis of problem universalizing, the work of Daugherty and Funke [2] done at Calgary University with students and professors reinforces he existence of obstacles, which are in common to all. The findings obtained by researchers while working with professors as to the obstacles, or changes imposed by online instruction take in were (through order of importance): 1) lack of technical support; 2) lack of equipment as well as adequate software; 3) amount of time required for material preparation and course managing; 4) holding back on the part of students; and 5) lack of institutional support.

Still on this same line of thought, two other studies show that there is usually poor performance on the part of online professors, as to questions pertaining to time and technical support, seeing as how very little or no importance is given to these items [5] and [8]. The later [8], goes as much as to say that the recognition of time involved in the creation of quality products, the development, and its setting up is still not yet agreed upon by the majority of Universities.

Similar results to the ones mentioned above, were also found in other researches done in other contexts, schools and countries [4], [11], [3] and [13].

As we can see, there is harmony in the results of reported researches, and therefore, there is an indication that there is a universalizing of obstacles found by professors in the online teaching process. Our intention is to bring it to accordance with the technological area, specifically in engineering courses.

UTILIZED CONTEXT FOR THE OBSTACLE VALIDATION IN THE ENGINEERING AREA

State University of Campinas (UNICAMP) is a public teaching institution that offers a range of knowledge areas, and levels of undergraduate and graduate courses; preferably through traditional methods. It stands out as one of the largest public universities in Brazil. It has 21 thousand students divided as follows: (55%) undergraduate and (45%) graduate students [12].

UNICAMP does not have clearly defined policies in relation to long distance teaching. Therefore, the observed reality is the existence of individual efforts of a small part of the faculty who is conducting pilot online teaching programs, in its majority, used as support to present teaching.

In the technological area, specifically in the Engineering School at UNICAMP, the scenario is not different.

Only a small percentage of UNICAMP´s school of Engineering faculty (not more then 5%) take or have taken the initiative to use the *Web* channel as teaching means.

Public Consulted

In its context, the encountered obstacle validation process which was found by professors in the long distance teaching process, specifically in the engineering area of UNICAMP, was restricted to a small sample of professors, making this limitation advantageous to the study, because we were able to opt for individual semi-structured interviewing with each one of the faculty members that used or are using the long distance teaching process, wishing to explain with more accuracy the individual perceptions as to obstacles encountered during their online teaching experience.

Table I shows the various schools of engineering at UNICAMP, and the number of professors that were interviewed in each.

TABLE I
SCHOOL OF ENGINEERING AT UNICAMP AND THE NUMBER OF PROFESSORS THAT WERE INTERVIEWED IN EACH LEARNING UNIT.

School of Engineering at Unicamp	Number of professors interviewed
School of Computer and Electric Engineering	4
School of Civil Engineering	2
School of Mechanic Engineering	2
School of Chemical Engineering	2
School of Food Engineering	2

Methodology

The interviews were done during April and May 2002, dates were previously scheduled, and, when authorized they were taped.

Each interview lasted for at least 30 minutes, and in some cases it lasted for as much as 2 hours.

RESULTS FOUND IN THE VALIDATION PROCESS

The interview was guided by the central question: "***what are the obstacles in distance teaching?***" Because of the format of the semi-structured interview, it was done in an open way, without limitations on the part of the professors when answering the questions.

The majority of the professors, who were interviewed, gave as the main obstacle "***time consumption in the***

development of the teaching material, and time spent for the redirection/conduction of the group (feedback) " In the words of one of the professors:

> *"The biggest obstacles are: time and preparation…you spend time to prepare the material, to help the students, and to work with the computer".*

Concerning *feedback* to students, another professor mentioned:

> *" In my attempts (long distance teaching), I used the e-mail as communication means. It was terrible! I wasted all my time doing this, and couldn't do anything else (more important)"*

As to the preparation of teaching material to be used, it was observed that, in the majority of the cases they were already available. They were not, however, in an adequate format or style to be published and or made available for the online teaching. In this sense, one professor points out:

> *"…it is obvious not only to the student as well as to the professor that to do such work (producing teaching material) isn´t an easy task. To write the text, for example, it demands a lot of hard work. I had already written a book on electronics, in which I referred to a course of latex, so I used this material as basis for the Classes. However, it had to be converted into HTML. The Whole conversion process demanded a lot of work."*

In the later report, in common with the set of interviewed people, goes what was identified as the second and biggest impact obstacle in the online set up process and production: "***the technological obstacle: lack of technical abilities in the handling of/ and limitations imposed by such technologies***".

There is an interesting comment made about the second obstacle:

> *"The main obstacle (in long distance teaching) is the lack of effective multidirectional communication. Interaction is jeopardized, thus reducing adaptation space according to the moment and group re-feeding. The tools used for communication nowadays are sufferable, to say the least".*

Besides the communication limitation, also another limitation was pointed out; the one related to the tools aimed at teaching material production. There is a particular aspect pertaining to the technological area, as pointed out during the interviews. In the technical engineering area, there is great need for concept expressing in form of mathematical formulas. These formulas need a tool that facilitates the construction and the publishing process. Therefore, we come upon the third obstacle, which is: "***the lack of specific tools for the technological area which facilitate material publication process***". One of the professors who were interviewed points out:

> *"…when you need to create material, just to think that one has to use equation editor, is hard enough, and there is no point in giving a long distance course unless you have appropriate material. You take twice or three times more time to use an equation editor, as you would if using a text editor or simply did it by hand. It's a great sacrifice".*

The fourth obstacle arises because of the limitations imposed by technology, and it is widely pointed out by the professors who were interviewed: "***the need to (re-learn) a new post as professor/tutor***".

A very pertaining comment came up regarding the fourth obstacle:

> *"The professor has to have it clear in his mind, that long distance teaching is not the same as classroom teaching. There is a difference in standard, and as such, it forces a change in posture in the process of participating agents, especially the professors' ".*

The majority of the professors' manifestation became clear as to the lack of incentives on the part of the institution, to support course transformation projects taught in the traditional way (professor present) to online format. Such manifestation points out another obstacle found: "***lack of clear institutional support to faculty members***".

The professors who adventure into such tasks are the ones who look for innovative processes, not worrying about the return or the institutional support. Here is a comment that emphasizes this obstacle:

> *"… if you can give a professor-present course in which you go there for 2 to 4 hours a week and see from 5 to 6 students because the others don´t look for you anyway, and when it's distance teaching, the ones that never look for you, come and ask questions just to say that they are taking part…and this unmotivates; seeing as how we don´t earn anything extra to do this. Therefore, most professors prefer to stick to professor-present classes only".*

The view that the "institution" does not support such processes can be verified by the views of many professors in the educational format of online teaching:

> *"… so, distance teaching demands a lot more work than professor-present classes, and sometimes this is not very well understood, and when other professors found out that I was teaching online, they asked: what does he do? Do you mean he doesn´t teach? What does he do during his class time? There is a lot of prejudice towards it, but these people are a bit slow, so they don't really*

understand this new way of educating, so I have to explain everything, and show that I spend a lot more time then I would if I were teaching a professor-present class; in which I'd show my ready made transparencies, with nothing new to add; so the teaching task is very small….it´s alright if stay in the classroom for two hours, but I take a lot more then two hours a week to do this online course!"

As for last, other obstacles were pointed out by the professors during the interviews; not in an emphatic way as the ones already mentioned, but that in a way cause a bit of worrying because they touch upon the effectiveness of the long distance teaching set up. Some of them are: lack of support personnel; excessive personal exposure: prejudice on the part of the students: and the fact that communication tools are still deficient.

Table II shows a summary of the main obstacles in order of importance: as they were pointed out by the professors of the engineering courses at Unicamp, while they undertook the long distance teaching process.

TABLE II
MAIN OBSTACLES FOUND BY PROFESSORS IN THE ENGINEERING AREA

Degree of Importance	Obstacles
1	Time used for the development of teaching material and for the conduction and redirecting of students *(feedback*)
2	Technology: Lack of technical handling abilities and limitation imposed by such technologies
3	The lack of specific tools for the technological area which could facilitate the publishing process of technical material.
4	The need to re-learn the new professor/tutor posture
5	Lack of clear institutional support to faculty members

FINAL CONSIDERATIONS

As first proposal, the research done with the faculty members from the Engineering School at UNICAMP, had as a goal, to identify the main difficulties encountered by professors while using the Web for teaching, and to compare them to the results of others researches done in others Universities and countries.

The validation process was successful, for the main obstacles that were pointed out by UNICAMP´s engineering professors, and they were coherent with the ones presented in other papers.

In this comparison, it was possible to validate the use of those papers in future researches in online teaching.

The only point not emphasized in the researche done, but which was highly high lightened by the professors in the technological area, was the lack of tools to facilitate the publishing process of technical contents/mathematical, like formulas, resolution mathematical processes, and technical drawings.

Therefore, we are aware that such obstacles were pointed out as being in conformity with all the professors during the process of setting up online teaching courses; no matter what the geographical location was, or its work area. The great difference in the powering of online teaching is in the bringing out of valid standards, and the construction of a new model, and a new teaching structure, proper for this new context.

ENTRY LEVEL PROBLEMS DIAGNOSIS, PARTIAL SOLUTIONS, THEIR EVALUATION AND NEW PROPOSALS

Darío Guaycochea Guglielmi[1], Teresa Merchand Hernández[2] and Jesús Hernández Villa[3]

Abstract *— Severe entry level problems are observed in the case of a Mexican school of engineering. Besides problems related to knowledge and skills in basic sciences, students lack study habits; the transit from annual to three month terms demands them to work under pressure and finally, social, economical and psychological aspects are involved. Not all the teachers, despite their scientific level, are concerned with these problems. Several actions have been taken: a program of professor-advisor, updating the curricula, welcome programs, leveling courses, improving the infrastructure and promotion of the SAI (Individual Learning System). Conception, strategies and results of these measures are described. Other actions are to be applied in the near future: promotion of the bachelor programs; study habits workshops; psychological support; increasing non-curricular activities; motivational events; a program of courses for the development of teaching skills and including professional subjects from the beginning of the career.*

Index terms — Advisors, entry leveling, individual learning, welcome programs.

INTRODUCTION

The Division of Basic Sciences and Engineering (CBI) of the Universidad Autónoma Metropolitana – Azcapotzalco (UAM-A) is located in the northern part of Mexico City. As a school of engineering, the CBI Division offers nine engineering bachelor programs, four master and two Ph. D. programs. A tenth bachelor program (Computing Engineering) is about to be opened by Spring 2003. Studies about graduates performance were done and their results are more than satisfactory; a high percentage of graduates are working in their professional field and the institution is increasingly recognized for its results, despite its youth (28 years in November 2002). As a contrast, entry leveling is one of the most concerning problems and its consequences are determinant for students advance. Desertion at the first levels is high and many of the students who stay have significant problems. An effort is being done to revert the situation. First of all, a diagnose was obtained and causes of the situation were identified. As a multivariate problem, it must be attacked from various fronts; strategies must be coordinated and a constant evaluation is needed. Some actions were already taken and others are under planning.

THE DIAGNOSE

The Universidad Autónoma Metropolitana is one of few high education schools in Mexico with three month terms. There are three trimesters per year (Spring, Fall and Winter). A trimester includes eleven class weeks and one more for final exams. Curricula are organized according to this; theoretical subjects normally comprise 49.5 hours and laboratory courses are programmed in eleven sessions of three hours. Bachelor programs consist of 12 trimesters (4 years) and about 70 subjects. There are two admission periods per year: Spring and Fall. Although between 700 and 900 candidates are admitted in a period, not all of them finally register; normally 8 or 9 out of 10 do. In extreme cases, such as Spring 2002, only 7 out of 10 new admitted students effectively registered. The first trimester is critical, because desertion is significant along this term. In some cases, only one half of the initially registered students remain active until the second trimester. In addition, other figures are significant to show the failure of the new admitted students, such as the accreditation rate in some subjects; Calculus I, for instance, has had an average of 35% per period between 1993 and 2001. It is difficult to determine the causes of this situation but some of them may be assumed as a result of studies and inquiries applied to students and teachers.

- Most of the new admitted students are used to semester or yearly terms. The adaptation to trimester terms force them to study under pressure. The advantages of this are evident, because the future professional develops skills and attitudes to work under pressure and adverse conditions. However, adaptation to this should be gradual.
- The students academic entry level is low, specially in mathematics.
- Students lack study habits.
- Students don't feel identified with the institution and their careers at the beginning. The institution organized few and infrequent motivational activities. Students are not organized in an association, although they share cultural and social activities from time to time. Until

[2] Teresa Merchand Hernández, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, mht@correo.azc.uam.mx
[3] Jesús Hernández Villa, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, jjhv@correo.azc.uam.mx

recently, there were no professional contents in the first trimesters; only basic sciences and some social subjects.

- Teachers, despite their scientific level, are not always concerned with the student problems and some of them lack pedagogical skills or training.
- The curricula spent many years without revision and updating.
- Poor promotion of the programs outside the University.
- Social, economical and psychological factors.

Considering this situation, some measures were proposed. Some of them were put in action and others are under planning. They are described and partial results are commented.

Advisors Program

There are three levels of autonomy in the University, with distinctive functions; increasingly: Division, Campus (Academic Unit) and the University itself. The CBI Division started a program of advisors in the trimester Spring 2000, on the basis of assigning a teacher-advisor to every new admitted student. This was difficult at the beginning, specially because advisors practice has little tradition in Mexico. Discussion aroused about whether it was convenient to select advisors whose professional profile was close to the student career or not necessarily; it must be pointed that successful experiences were achieved in both cases, in the U.S. and England, for instance. At the beginning, it was decided to assign advisors regardless of the career but it was noticed that the students wouldn't approach their advisors; so the policy was changed. By Spring 2002, the advisors program was assumed by the Academic Unit, as a consequence of a scholarships programs. It was conceived as an educative service created to follow up the students formation process, as individuals and as a collective, and an opportunity for planning and designing strategies to develop students skills and attitudes. Particular objectives are: to facilitate the students integration to the University; to advise the students for decision taking regarding their studies; to promote criteria and attitudes to contribute to the students' autonomy; to help the students to the early identification of common problems in the studies and to assist them to find solutions; to encourage the rational use of the resources offered by the institution and to contribute to the self evaluation process undertaken by the University. Partial results of this program are not really encouraging; students do not meet their advisors as often as they should, even at the advisor's call. The conclusion is that it's a cultural matter, which only practice and insistence will revert.

Updating the curricula

This is a difficult task in this University for various reasons. The democratic organization of the institution demands that many sectors are to be consulted to take such decisions and the three government bodies (corresponding to the Division, the Academic Unit and the University) have to approve the proposals. Another feature is that the different careers share subjects, not only in the basic level but also in advanced trimesters; this happens for instance with environmental dimension or systems engineering subjects and more emphatically in careers with common interests; thus, the updating of one career necessarily affects others. Finally, regulations demand that only one program must be in force at a time for the same career; so, when a program is updated, the academic record of every student must be converted into the new one. By 2000, the curricula of all nine bachelor programs accumulated a considerable delay in their updating, despite remarkable initiatives; only local and limited revision was registered. A great effort was done in 2001 and 2002; the programs of the nine careers were revised and even a new career was created. Once the programs were updated, all of them applied for accreditation to the CACEI (accreditation board for Mexican engineering programs), a practice of increasing importance and recognition in Mexico. Obviously this kind of actions is very important but, how does it help the first level students? Some elements considered in the changes were directed to this. In some careers the number of credits in the first trimester was lowered, in order to make easier the transition to the university life. The curricula structure was changed into a more flexible one; the prerequisites to take some subjects were suppressed; when the previous programs were in force, students who didn't approve math subjects of the first trimester, weren't allowed to take physics subjects of the second one, with severe consequences for the advance in their studies; this condition was canceled. Some careers introduced professional subjects in early stages. Finally, modern techniques were introduced for evaluation and teaching itself. Updated programs were put in operation in October 2002; a permanent follow up is planned to evaluate the results.

Welcome programs

The Academic Unit has always offered welcome programs to new admitted students, to get them introduced to the university life. The Divisions and Programs Coordinators have also contributed to this activity, although less regularly. An effort was done since 1999, to coordinate the participation of the different institutional branches and even students groups in a program called PIVU (Integration to University Life Program). It is essentially a one day event directed to promote an integral relation between the new admitted students and the University. It is conducted during the first week of the trimesters corresponding to admission periods (Spring and Fall). Its particular objectives are: to offer the new admitted students a global vision of the services offered by the University; to give information about the academic, cultural and sport activities, about the student's rights and duties and where they can get specific information and support; to promote a sense of belonging and identification with the institution. Activities are: information stands about the careers, information stands about institutional services (foreign languages, cultural activities, sports, computer services, library, school administration, educative orientation, graduates, medical services, etc.); an artistic event, such as a concert, is generally included. Again, the students participation in these activities is never as wide as desired; however an opinion poll applied to them showed the following results: They consider that the PIVU is an important event to know the services offered by the institution; they feel important for the University; they believe that more publicity is necessary and that advanced students should cooperate more.

Leveling courses

Most new admitted students have an insufficient background, particularly in mathematics and physics. This has lead to think that leveling courses could be a chance to level them to the basic sciences courses of the first trimester. Opinions vary from dedicating a whole trimester to these courses and make them compulsory for students who are unable to pass a special exam, to those who propose to set them as optional courses for the students, limited to a period of one or two weeks, prior to the formal teaching. A document produced in 2000, for instance, suggests that students with deficiencies in basic sciences should take a set of courses during one trimester, including mathematics, physics and study habits; the student is supposed to dedicate full time to this activity. However, this was never put into practice. Instead, a set of mathematics, physics and induction to the University sessions was offered since Winter 2002; although this is not an admission trimester, the course was initially offered for students who had been admitted in Fall 2001 and, for some reason, decided to inscribe later. This first time only 8 of them attended the sessions but in Spring and the Fall that figure grew to more than 70, about 10 to 15% of the total number of admitted students. The effort was successful, particularly regarding the permanence of the participants in the school. Considering this experience, it is planned to offer a module of support courses for new admitted students, during the first trimester, simultaneously with regular subjects. This will start in Spring 2003.

Improving the infrastructure and promotion of the SAI (Individual Learning System)

This is an alternative to the traditional teaching-learning method. Its most important features are the following: excellence learning, as a possibility for every student; active participation, this requires than the student plays an active roll in the learning process; and positive reinforcement, suppressing every element related to penalties. As an individual learning system, the SAI teacher acts as a guidance and a learning facilitator for the student but must provide him (her) with material enough for the lessons. The SAI allows the student to advance at his (her) own rate; he (she) may even spend two trimesters for a certain subject if necessary; exams are more frequent and with less contents than those ones of conventional courses. That's why this system is suitable for slow progress students as well as for high efficiency ones. Not all subjects are offered through this systems but most of the basic level ones are. Other limitation is the resources dedicated to this program but considering its importance and potential to help students, they were increased in recent years. Promotion of the SAI is sometimes difficult because students are not used to play an active roll in the learning process but students themselves are the best promoters, because those ones who have the experience are generally satisfied and come again. Another important fact is that an extra effort was made to help, through the SAI, students who have failed in their first mathematics courses.

Promotion of the bachelor programs

The University is located in one of the largest urban concentrations in the world, with more than 20 million inhabitants. Despite this impressive market, there are more than 20 schools of engineering in the area, either public or private ones. Some of these institutions include high schools, which are natural providers of candidates to professional programs; the UAM doesn't, as it is established in its Organic Act. Publicity is difficult because it's very expensive to reach to so many people and the budget for this purpose is limited. Thus, the most suitable way to promote the bachelor programs and to get more and better candidates is going to selected high schools; presentations, conferences, brochures, panels and stands are adequate means for this objective. Some Program Coordinators have had initiative enough to follow such kind of activities by themselves. The Metallurgical Engineering Coordinator (co-author of this paper), for instance, has participated in radio programs, visited high schools and secondary schools, conducted guided visits in the University, wrote a manual with a study about the Division promotion and participates in a periodic event called October. Science Month, organized by the CONACYT (National Council of Science and Technology). Other experiences show that the presence of advanced students in visits to high schools is strongly motivating for potential candidates. It's expected that the programs accreditation will increase the prestige of the Division and will become a fine credential for its promotion.

Psychological support

Important help to students is given by the Office of Educative Orientation and Psycho-pedagogic Support, which depends on the Academic Unit. The psychologists team of this office give professional care to students who suffer from addictions, personal or familiar problems and, if necessary, patients are sent to specialized centers, linked to the

University by formal agreements. Another activity of this office consists of giving professional orientation to students, specially through workshops; it must be pointed that many students select their career without a proper orientation and with this kind of help, they have a new chance for their turning point. Several events are organized by this office, such as lectures, workshops and video showings, related to subjects such as VIH-AIDS, addictions and emotional cycles.

Motivational events

It's important for students to feel that their effort is recognized by others, including the institution itself. A program of awards for excellent and very good performance students was established in 2000 in the Division CBI. Standards to define both categories include marks average and number of credits approved in the previous trimester. Awards are granted in a ceremony with the assistance of the President of the University. Other actions in this front are lectures and seminars, conducted by successful graduates; they are organized by the Program Coordinators; the example of the Mechanical Engineering Coordinator is remarkable.

Program of courses for the development of teaching skills

One of the most important elements of the teaching-learning process is the teachers. Although their academic level is high compared to the average schools of engineering in Mexico, not always their pedagogic skills are similarly good. A program of courses for the development of teaching skills was launched in 1999 to contend with this situation. Courses are offered in the periods between trimesters. Fourteen different titles were given, some of them as many as four times. Engineering teachers demand with preference the following courses: Learning Evaluation (the most demanded one), Didactics and Teaching Techniques, Learning to Learn, Educative Multimedia and Group Techniques Applied to Teaching. As a result of this program, teachers get increasingly involved and encouraged to take this kind of training.

Other actions

The Mathematics Club is a space, operating since 2001, where advanced students help their fellows of the first trimesters with their studies. An idea under planning is the organization of a study habits workshop, in order to help students to organize their time and to develop correct study habits and techniques. Information systematization is another task undertaken by the University, to provide teachers, authorities and even students, with enough information in real time to make diagnoses, analysis and to evaluate results. The development and implementation of modern teaching techniques are also important; the University purchased specialized software to promote web based teaching, which is already used by many teachers and a related project was approved in the Division.

PROGRAM FOR LEARNING STRENGTHENING: EXPERIENCES, RESULTS AND PROSPECTIVE

Teresa Merchand Hernández[1], Jesús Hernández Villa[2] and Darío Guaycochea Guglielmi[3]

Abstract *— Performance and efficiency of an educational institution depend on different factors: academic and administrative policies, curricula, resources and infrastructure, students and also the teachers and their training The analysis and solution of the problems faced by the institution demand an integral focusing of the different sub-systems; in this sense, quality will be the result of the coordinated promotion of all the elements as a whole. Regarding the improvement of the faculty members academic level, the CBI Division of the UAM Azcapotzalco has implemented different strategies; however, they had little influence in teaching-learning indicators. The Program for Learning Strengthening consists of the diagnosis and attention of deficiencies in teaching skills through basic pedagogic training courses. This program is based in modern educative trends and aims to develop, not only skills but also attitudes in the teachers, to promote the students success.*

Index Terms *—Didactics, pedagogy, teaching administration, teaching formation.*

BACKGROUND

The Universidad Autónoma Metropolitana (UAM) is the third university in Mexico, regarding students population; it was founded in the 1970s with an innovative model, in which, the figure of teacher-researcher, the trimestral terms system and the departments organization, have been distinctive features. At present, programs for the effective attention of teaching problems is an institutional concern. This paper describes the Program for Learning Quality Strengthening, promoted in the Academic Unit (Campus) Azcapotzalco of that institution since 1999; depicts a revision of experiences and shows the short and medium term perspective of the program.

THE CHALLENGES OF THE UNIVERSITY FORMATION

Since teaching is one of the main functions in the university system, it faces the challenge of producing human resources with an integral focus. From the point of view of the engineers formation in Mexico, the teaching practice demands the inclusion of new needs, derived from the discipline evolution: the command of pedagogical knowledge and skills; a teacher's attitude which recognizes the education as an essential element of change; the insertion of activities to encourage the students effective learning; as well as other aspects, such as the comprehension of the new information and communication technologies and their use in the educative practice. This context as a whole will help to bring a more professional focus for high education teaching. After three decades of the UAM foundation, period in which its professional programs have been operating, significant changes happened in different aspects of the human life: economy, politics, society, science and technology. This changes have affected production systems, professional work, information management and in general, the way of solving problems. Together with this, the demand of professional abilities such as: team working, decision taking, formal languages knowledge and autonomous learning, reinforce the university commitment to achieve an integral formation for graduates, and to set up a real platform, so that they get a professional development and display their skills. In this sense, the challenge of the high education institutions is to give the students a solid scientific and technical formation, as well as to develop and consolidate skills and attitudes, professionally, personally and intellectually, to cover graduates and employers necessities in a highly competitive, changing and global environment. An integral formation will facilitate the graduates their incorporation to the professional field and to different opportunity areas in the productive sector or to follow their academic formation through postgraduate or permanent education programs.

THE ROLL OF ACADEMICS IN STUDENTS FORMATION

Teachers are the central axis, among different elements in the university, for the educative project, its viability and fulfillment. They are who know, interpret and recreate the curricula; design strategies; apply and adapt educative material, as another way to make academic contents more accessible; moreover they generate a favorable climate within the classroom to get a significant learning and a quality education. However, teachers, at least in this institution, used to face several difficulties, such as insufficient material and infrastructure, the lack of an integral organization for teaching, absence of a program of

[1] Teresa Merchand Hernández, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, mht@correo.azc.uam.mx
[2] Jesús Hernández Villa, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, jjhv@correo.azc.uam.mx
[3] Darío Guaycochea Guglielmi, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, sacbi@correo.azc.uam.mx

induction to the institutional educative model and absence of a permanent pedagogical program to support their performance. To solve this, it's essential to implement policies and programs to make effective the teaching functions development. There's no doubt that the success of any educative model or improvement program, should become clear in the classroom; that's why it's important to promote programs to improve the teachers performance, under the basis that the more the teachers are trained, the better and more effective will be their results.

TEACHERS STAFF CHARACTERISTICS

The institutional tendency to the strengthening of academic teams, was centered in teacher's disciplinary improvement through postgraduate programs. Although the command and deepening in a discipline is an important factor for teaching practice, a program based essentially in the acquisition of an academic degree, attends just one of the aspects of teaching performance improvement. At present, about 50 % of the teachers in the UAM Azcapotzalco completed postgraduate studies, and this feature is recognized as one of the strengths of this school in the nation. The teaching staff is integrated by part time, half time and full time professors in three categories: assistant, associate and tenured; and also by academic technicians and aides. The Academic Unit Azcapotzalco, as well as the two other units in the UAM, stands out for its high percentage of full time professors (73 %), a less presence of half time professors (13 %) and part time (14 %). These data reveal the institutional concern to conform an academic staff with a professional activity, focused essentially to education. Regarding the postgraduate studies followed by the academics, they have a close relation with a deep and specialized knowledge about a study object related to the professional teacher's discipline; this formation allows him to propose, formulate and develop research projects in a field.But this is not directly related to teaching effectiveness.

TABLE I
DISTRIBUTION OF ACADEMIC DEGREES IN THE TEACHERS STAFF OF THE THREE DIVISIONS OF THE UAM AZCAPOTZALCO

Degree	Basic Sciences & Engineering	Social Sciences & Humanities	Sciences & Arts for Design	Average
Bachelor	40.8 %	48.8 %	66.1 %	51.6 %
Master	37.4 %	30.6 %	24.3 %	30.7 %
Ph. D.	21.8 %	20.6 %	9.6 %	17.7 %

The development of teaching skills is important, as it is the disciplinary improvement. It's necessary to facilitate the teaching formation to academics, through a program identified with the peculiarities of the institution, the curricula, the subjects given by the teacher and their relation to others. Regarding this issue, some unconnected actions were carried out in the Academic Unit and the result was a limited knowledge about techniques, methods, strategies and procedures to contribute to the professionalization of the teachers activity; however it's necessary to promote reflection about the implications of teaching under a focus of integral analysis.

ACTIONS UNDERTAKEN FOR TEACHERS FORMATION

Regarding teaching formation, the institution has passed through diverse experiences along its history; some particular efforts can be remarked. That's the case of the Commission for Academic Support and Development (CADA); this office was created in the early stages of the institutional life and initially focused its activities to the support for the development of the departmental organization and the formation of basic academic groups to satisfy curricular necessities; this lead to carry out a project, which involved a considerable part of the early academic community, for the design of curricular programs following the institutional model. CADA assisted to academic and psycho-pedagogical support to students in the 70's and 80's; this task was later assigned to the Professional Orientation Office. As well, the national educative tendency of those years was supported by CADA, through the organization of different courses and seminars in subjects such as: basic didactics, objective-oriented curricular design, didactic material design and learning evaluation. These courses had a limited and restricted impact, regarding the number and kind of teachers who participated. They didn't conform a permanent program, although solved particular problems and demands of that moment. Another set of actions, carried out by CADA in the 80's and 90's were related to the organization of short courses for teachers, about different subjects, mainly computer skills. In recent years, CADA transformed its structure and at the present offers support to teachers, through: promotion of scholarships program for postgraduate studies in the country and abroad; search of financial support by means of agreements with other institutions; and promotion of academic exchange for the development of scientific and technological research.

ANALYSIS OF THE STUDENT'S INQUIRY.

The opinion of students is important to orientate the strengthening quality teaching program, It was taken from a survey. A survey is regularly applied to students between the 6th and 7th weeks, each trimester. One of the purposes of the instrument is to know the opinion of the students. regarding the acting of their professors. The survey includes three parts, one of them is dedicated to evaluate the students performance in the course, another part shows important elements of the professor's acting and finally it has a part that gives the students the possibility to write free comments to expose opinions or recommendations about the course or the professor's work. An analysis was done on a sample of 1063 free comments extracted from the survey, selected from the three levels of engineering careers: basic level, basic professional and concentration areas. The student's comments were classified in professor's acting, curricula structure and infrastructure. Regarding professor's acting results were classified in function of domain of three aspects: knowledge, command of teaching abilities and capability to transmit values and attitudes. The analyzed information emphasize the follow aspects:

- Most of the students recognize the high academic level of their teachers.
- They value apprenticeship that comes from professors who have professional experience additional to teaching experience.
- They demand an education based in concrete applications besides of theoretical approach to the topics.
- They show the necessity of doing evaluations closely related to the courses objectives.
- Comments show the necessity to reinforce educational skills of the professors; for example: ability to give appropriate rhythm and correct level to different parts of the course, enhancing personal aspects, such as voice management; leading students to learn processes with effective strategies instead of teaching practices based and focused in professor's activities.
- Also the students refer the necessity of improving motivation, equal treatment and achieving better communication and cooperation between students and professors.

RECENT ACTIONS. PROGRAM FOR QUALITY LEARNING STRENGTHENING

In order to attend specifically the teaching formation of the faculty members, as well as other problems related to educational aspects, The Coordination of Teaching (COD), depending on The General Coordination of Academic Development, was created in the UAM Azcapotzalco in April 2001. At the present, the work of this Coordination refers mainly to the *Program for Learning Quality Strengthening*, which in turn is divided into three sub-programs:

- Program for teaching formation and upgrading;
- Program for educative innovation and curricular implementation and
- Program for planning support, follow up and evaluation of teaching.

Prior to the creation of this office, the first of this programs was already put in force; different courses were offered for teachers, with the following titles: Introduction to the teaching process; Planning and formulation of learning objectives; Group techniques applied to teaching; Production of didactic materials with the use of electronic media; Production of multimedia didactic materials; Effective education and micro-teaching; Introduction to the teaching-learning process; Groups dynamics; Didactics and teaching techniques; Learning evaluation; Learning to learn; Learning to think; Development of intuition and perception for learning; Didactic planning and Descriptive chart elaboration.

The courses with highest demand by engineering teachers, in decreasing order, are: Learning evaluation; Didactics and teaching techniques; Learning to learn; Production of multimedia didactic materials and Group techniques applied to teaching.

The average offer of the courses was four per period between trimesters (twelve courses per year); they have been conducted in total in ten periods; they comprise 20 hours; 220 professors of the three divisions have participated; the share of each division is almost equal; it shows that the interest is similar, regardless of the professional field. The criteria for the course selection was to look for a basic proposal to attend practical-methodological aspects, focused mainly to help the teacher in planning, performance and evaluation activities. However, articulation and harmonization of efforts in very important, in order to consider the diverse aspects which lead to a professional teaching function. Thus, it's very important to design and put in force an integral, well defined and permanent program, with the objective of enriching the formation of the academic staff with knowledge, skills and attitudes, to help them to achieve an optimal performance as teachers. So, the integral program for teaching formation and upgrading in the UAM-Azcapotzalco is being defined looking for three particular objectives:

- To get the introduction and incorporation of the teacher to the institutional model, through a project of induction to the teaching function.
- To design a project of basic teaching formation directed to attend different didactic-pedagogical aspects, to improve activities for planning, conduction and evaluation of the teaching-learning process.
- To contribute to the disciplinary formation of teachers, through a project of specific teaching formation, derived from necessities in the divisions.

At the same time, the following activities are suggested, to strengthen the production of didactic materials, reflection about teaching and administration:

- Lectures given by guest experts.
- Courses and seminars with the support of teaching administration experts.
- Cooperation with other branches of the university to incorporate new communication and information technologies in the teaching-learning process.

- Promotion of didactic materials production using new technologies and favoring distance learning.
- Development of evaluation projects to identify and to plan solution to relevant teaching practice problems in the Academic Unit.

PRELIMINARY RESULTS OF THE FORMATION COURSES

As mentioned above, the Program for Quality Learning Strengthening began in 1999. Different courses were offered since that date; the quantitative impact of the program has been approximately 700 inscriptions. At the end of each course, a survey is always applied to identify the participants' opinions, regarding contents, instructors, and the strategy itself. An analysis shows the following results:

- The professors make evident the necessity of offering a more structured program, capable to link and give sequence to the courses' contents.
- They demand an institutional recognized teaching program.
- They suggest more levels for different topics that can be structured either in a wide permanent education program or in a master program in education.
- They mention how they have improved their teaching abilities after they have taken some courses.
- They mind greatly about the importance of their work in education.
- They declare to have achieved critical and reflexive thought about ways to improve their activity.
- They recognize teaching as a collective, interactive and dynamic activity that includes students and teachers.
- They give importance to the search of strategies to allow them to achieve a better knowledge.
- They mention the necessity of programming more practical sessions and linking the topics in the teaching courses with the objectives of the courses they offer.
- They suggest to explore other ways to access teaching courses, for example web and multimedia supported distance education.

FURTHER ACTIONS

The following topics are considered as essential aspects for the basic teaching formation; to be implemented with courses, activities and with projects conducted by teachers collectives:

- Significance of the educative work
- Pedagogic competence
- Design of learning objectives
- Teaching evaluation
- Classroom communication and team work
- Strategies and styles of teaching and learning
- Implementation of educative projects by electronic media

To get from the teachers a different form to give his classes it's necessary that they gets a different formation, answering the following questions:
What's the formation to be encouraged?
What are the characteristics to achieve in the graduates?
What are the mechanisms to get these qualities?

It's very important, for the **specific teaching formation**, to consider the particular necessities for each knowledge field, taking into account that the teacher bases his didactic action on what he has received. In engineering courses, for instance, it's necessary to support the process in the skills and attitudes to be promoted in students, such as: analysis and synthesis abilities, alternatives analysis, searching capacity, team work, identification and application of strategies for problems solution, incorporation of the systemic thought and the relation cause-effect.

CONCLUSIONS

Teachers profile and formative requirements. Analysis of cultural characteristics and emergent demands, allow to depict the required general profile of the XXI century high education teacher:

- Reflective and autonomous person, capable of acquire permanently professional skills, through observation and systemic registration of actions; conscious of his acting and of the effects produced in students.
- Prepared for the design, evaluation and reformulation of strategies and innovative pedagogic programs, with comprehensive knowledge of techniques and methods, which he employs, evaluates and improves, modifies or creates other more efficient methods.
- Capable of systemic research and permanent reflection about his professional practice, basing his decisions on the critical application of upgraded specialized knowledge; which he understands and uses properly in the processes and methodologies of the disciplines or disciplines he teaches.
-

CHALLENGES OF THE NEW PARADIGMS IN THE RELATION TEACHER-STUDENT

Jesús Hernández Villa[1], Darío Guaycochea Guglielmi[2] and Teresa Merchand Hernández[3]

Abstract *— Traditionally, the essential element of a good teacher in higher education levels, used to be the command of a field of knowledge. In recent decades, the importance of pedagogic aspects was increasingly recognized. At the present, technological progress and its application to the teaching-learning process, are determinant for the relation teacher-student and demand the former to accomplish a more effective learning and to use new tools and resources. Modern teaching faces important challenges, such as the transition from the paradigm of the teacher-authority to the teacher-promoter of learning and human development; the increasing critical attitude of the students; the development of new skills and the necessity of a more active roll of the student in the process. This paper presents a background, the results of a questionnaire applied to teachers of the institution about this aspects, proposals and conclusions.*

Index terms — *Modern teaching, Relation teacher-student, teaching-learning process*.

INTRODUCTION

One of the essential elements in current education is to improve the communication process among teachers and students. To overcome some problems that the student faces to access to education when he inhabits rural areas or when he lives in large cities, is a difficult task. They have to cover long distances to attend school, with consequences such as: thousands of unproductive hours employed for transportation, less time for personal and professional activities, physical fatigue, stress and other problems as pollution, expense of energy, risks and insecurity. All these elements outline the necessity of looking for alternative models, capable of facilitating the communication among teachers and students.

In this sense various authors point that distance education presents characteristics, such as:

- Good cost/benefit balance to satisfy the necessities of the formation.
- Extension of the formation to organizations and collectives.
- Reinforcement of the inter-regional and international transfer of experiences, conclusions and formative materials.
- Demand of students commitment and high motivation level.
- Responsibility of the student himself in the learning process.

The introduction of new learning methods like the above mentioned ones and others, is modifying the idea of centering the teaching-learning process in the school. This fact, together with the relatively recent incorporation of new communication and information technologies, opens new horizons for the education, offering real possibilities of increasing satisfaction for a growing number of people, interested in institutionalized education but living in distant areas.

With reference to the means, the use of video, audio, television broadcasting and incorporation of the new communication technologies like: electronic mail, virtual spaces, real time communication and satellite connections, among others, generate many expectations regarding education productivity and effectiveness.

ANALYSIS

A. – Net supported teaching and its characteristics

Teaching based on the support of computer nets is a resource which has achieved, and still registers, an impressive development. The interest in this tool type has generated great discussion and controversy, as well as a great deal of literature about the association between technology and its applications to education. In some discussions, qualities that, in fact are not inherent to net based teaching are attributed to it; although they were already observed in other teaching methods, not necessarily associated to computers nets. Distance teaching and individual teaching share some advantages with web based education. The following table shows in brief a chronology of the world development of non-present education.

[1] Jesús Hernández Villa, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, jjhv@correo.azc.uam.mx
[2] Darío Guaycochea Guglielmi, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, sacbi@correo.azc.uam.mx
[3] Teresa Merchand Hernández, Universidad Autónoma Metropolitana Azcapotzalco, México D.F. México 02200, mht@correo.azc.uam.mx

TABLE I

Brief chronology of the world development of the non-present education

Date	Place	Observations / Comments
1728	Boston Gazette	Self -instructive material sent to students by mail .
1840-1843	Isaac Pitman. England	The Phonographic Mail Society is created; its objective is to deal with shorthand exercises corrections
XIX century	Thomas Foster and the Mining Herald (Pennsylvania paper).	Attempt to teach mining and prevention of mine accidents.
XIX century	Industrial cities of Western Europe and the U.S.	Effort to help people who didn't attend regular schools, due to various reasons.
1938	Victoria, Canada	The first formal action to promote distance education. The First International Conference on Mail Education is carried out.
1939	France	The National Center of Distance Teaching is created, to assist war refugee children by mail.
1947	School of Letters and Human Sciences, Paris, France	Masterly classes in almost all literary subjects were broadcasted by Radio Sorbonne.
End of 2nd War World	Central European countries and developing nations.	Literacy plans and other popular education programs.
60´s and 70's	Various countries	A broadcasted high school program starts operations in Spain. The University of Delhi creates a department of mail education. The Telesecundaria System is created in Mexico in 1968. The Open University is created in England in 1969.
80´s		Distance education evolves into a truly interactive tool with videoconferences application.
90´s		A new pedagogic attitude places the student in the first line and the institution in second place. Computer nets reach great development.
End of the 90´s and beginning of the XXI century		Offers cover different levels of the education (systematic, non systematic, professional, training and permanent education).

It's interesting to point a fact which can explain the quick spreading of computer nets based teaching, in particular through Internet, as one of many applications of this technology. Since the emergence of the radio, forty years passed until this communication medium reached 50 million receivers in the United States; television reached that number, in the same country, in thirteen years; but only four years were necessary for Internet to get such a number of users in the U.S.

Internet possibilities include the transmission of knowledge, images, texts, sound, animation and even dialogue in real time, to a multitude of users, wherever they are located in the world, at a reasonable and decreasing cost. Consequences in present teaching, as well as in distance teaching, are obvious but it is evident that the impact is observed mainly in the latter. Indeed, distance education registers a deep transformation with Internet tools.

It is necessary to point out that several tools have been developed for the implementation of teaching with the help of computers nets; some of them reached wide acceptance. These tools differ in hardware requirements and training level for their use. Some of the most popular ones are Blackboard, Mentor ware, Learning Space and WebCT. None of them is probably the best for all the approaches and science fields.

Michael Dertouzos, in his book "What Will Be", states that there are still some questions to be answered, regarding learning with the use of computers:

Does it improve the capacity of the students retention?
Does it help to build complex ideas starting from simple basis?
Does it improve the capacity for problems resolution?
Does it provide new perspectives and conceptual horizons?
Does it promote a better cooperation among students?
Does it strengthen the feeling of belonging to a community?

From the point of view of the evaluation, the new technologies present a great challenge for academics and researchers. It is not only necessary to evaluate the academic capacity but also other variables which are extremely difficult to measure; for example: the students emotional learning and the student's identification with the educational community.

The support, not the substitution, of teaching based on nets to present teaching, is an aspect with a very important projection, for it provides the teacher with a set of new teaching means, not to replace, rather to complement conventional ones, such as audiovisual means and even the use of the computers not necessarily associated to nets.

Regarding this aspect, the World Conference on Superior Education, sponsored by the UNESCO, in Paris, October 1998, produced a document which had wide dissemination: "World Declaration on Higher Education for the Twenty First century: Vision and Action" Its article 12 is entitled: "The potential and the challenge of technology"; it declares that "The rapid breakthroughs in new information and communication technologies will further change the way knowledge is developed, acquired and delivered …" and that they…" offer opportunities to innovate on course contents and teaching methods and to widen access to higher learning. However, it should be borne in mind that new information technology does not reduce the need for teachers but changes their role in relation to the learning process and that the continuous dialogue that converts information into knowledge and understanding becomes fundamental."

B. - Prospective trends in education

The revolution in the educative process conception involves different elements; not only Internet, demanding a new role by the teacher, the student and the institution. Flores Ochoa suggests the trends of the education for the next decade:

1. Tendency to decentralize the education, detaching it from the classroom, the schedule, the fixed group of students and the professor's constant look. (non-present, non formal education).
2. Tendency to substitute the technical school for the direct presence of the students in the production centers. These last ones spread to assume the technical training and the professional formation of the employees more and more intensively, considering the growing distance between the technological advance of the companies and the technical backwardness of the schools.
3. Tendency to a less massive education and to emphasize the individualization through two different roads:
   - Allowing such curricular flexibility, so that each student can self-design his own curriculum based on his characteristics, interest and capacity.
   - Increasing the use of more totalizing multimedia, mainly those that present higher versatility and interactive communication.
4. Centers of cultural and scientific-technique information with guides instead of teachers; they will replace little by little the conventional schools.
5. New strategies for the search of information will be promoted beyond the formal logic, the memory and the simple conceptual discrimination; more global, holistic strategies, creative intuition, evaluative synthesis, etc. as an effective answer to the quick explosion of new knowledge.
6. In the intricate and dispersed tangle of ideas, knowledge, theories and ideologies of all type, the contemporary teacher needs to recycle his function of keeping and transmitting information, to become an universal sensor and, at the same time, a fine conceptual selector of the range of his specialty with research capacity in the area. Thus, he will guide, with security and authority, the first steps of those students not included in his specialty, and at the same time fortify the creative abilities of students who are in his specific field.
7. The new teacher's authority shall be supported in his knowledge, and it won't require the imposition of the institutional punishment to be accepted. His task is neither to dictate class, nor to give instruction, nor to transmit formulas, theories or concepts. The student is the main actor of his new knowledge, the teacher is rather a guide at the shade, a slope that the student should discover.

CONCLUSIONS

Today, more than in other times, the prevailing idea of a school is the space in which the individual is linked with other individuals and with his environment; a learning process which goes beyond the classroom walls, in which a communication process is established to drive the student to modify, to enlarge and to enrich his formation outlines.

In this sense, the man's and world's transformation have been achieved through interaction among men, in which individuals and peoples who have not expressed their word were left behind.

As Paulo Freire refers in "The Pedagogy of the Oppressed": " Blocking the communication transforms men into objects"; he also mentions how the more quickly the interaction begins, the more revolution will be got in terms of learning.

These concepts, which go clearly against the traditional practice, were called by Freire "bank education". This is essentially anti-dialogical and non communicative; it continues existing in the environment of the education, in spite of the desire to overcome it.

Leaving the traditional paradigm behind implies for the educator to be removed from the protagonist paper that this model grants him, to open the way to educational models which grants the student's learning the central place in this process and where the means only constitute roads that facilitate the communication.

Therefore, the interactive process with the help of web, which is the professor's responsibility, will promote a climate of trust to encourage the students, freely and without restrictions, to express doubts and questions related with problems of adaptation, learning or advance. These problems represent, among others, causes which interfere with the learning process.

The professor's function, with the support of communication and information technologies, will consist of designing the road to create, to maintain and to promote for the student aspects like: the internalization of knowledge for his learning, the development of his expression capacities, the inquiry capacity, the discrimination and the development of his critical capacity as elements to be selective, regarding the information accessed through various information media; also the modification of outlines, attitudes and values which lead him to achieve an ethical and responsible behavior and which offers him the real possibility to share experiences, as well as the feedback and evaluation, as inherent aspects to the teaching-learning process.

A new paradigm arises in this context; the formation with be supported in the communication and information technologies, which gather those forms of information susceptible of being digitized, such as: text, sound, graphics, fixed image and in movement, etc.

A mixed methodology with a present-virtual outline, where the student attends classes and carries out other academic activities with support of the electronic means of information, would allow him to contact the school regardless of the schedule, encouraging the possibility of an almost permanent contact. Examples of those academic activities are: consulting, problems delivery, work in group, search of information, gathering, handling and analysis of data and other administrative services, such as inscriptions, studies revision, administrative steps and records.

Communication through these means, using email or teleconference, would allow to promote analysis and discussion on diverse topics, the formation of small groups to comment with their advisor or their equals the revised contents, for feedback or to exchange experiences with other groups of other countries that are studying the same matter.

Therefore, the challenge of the current education, consists of how to take advantage of the technology; since independently of the selected methodology, it will promote an effective communication among students and teachers, in the same way that incorporation of computer science and the use of various technological means supporting the education, imply a paradigm change in the relationships among teachers and students.

As Litwin refers, "The new information technologies have created new communication forms, new work styles, new ways to access and to produce knowledge". It could be added to that... "and the acting of a new relationship teacher-student".

Finally, it should be pointed out that not all the virtues attributed to the computer nets based teaching are exclusive. By no means they arose with it. The truth is that distance education doesn't begin with Internet, neither the systems of individualized or tutorial learning, in which the student can study at his own rate and play a more active role in the process that the one he takes in the present teaching.

USE OF VIRTUAL MANUFACTURING CONCEPTS IN ENGINEERING EDUCATION

R. Radharamanan[1]

Abstract — *In this paper, Virtual Manufacturing (VM), an emerging technology, that provides the capability to "Manufacture in the Computer", and the modeling approaches necessary to realize VM are presented and discussed. VM has the ability to interchange models between their use in simulation and control environments. The use of VM concepts improves decision-making and quickly achieves products with high performance and quality at a low cost. VM can provide accurate and realistic means to predict schedule, cost, and quality; address affordability as an iterative solution; and bridge the gap between engineering (design) and manufacturing in an interactive fashion. The benefits, costs, limitations, and risks associated with adopting VM are highlighted and discussed. The use of VM tools and concepts such as Virtual Reality, and Web-based learning in engineering education are presented and discussed.*

Index Terms — *Virtual manufacturing, virtual organization, agile manufacturing, virtual reality, web-based learning in engineering education.*

INTRODUCTION

It is known that acquisition strategies require the capability to prove the manufacturability and affordability of new products/systems prior to the commitment of large production resources and/or to shelving the system for restart in the future. Loosing the manufacturing capability and experience in production is a major risk in the current manufacturing environment [6, 8]. Maintaining the state-of-the art manufacturing proficiency without actually building/ manufacturing the products is a major challenge. Virtual Manufacturing meets the above challenges by providing the capability, in essence, to continue manufacturing in the virtual world of the computer. Through the use of distributed manufacturing modeling and simulation, VM enables the enterprises to evaluate the producibility and affordability of new product and/or process concepts with respect to risks, their impacts on manufacturing capabilities, production capacity, and cost.

Virtual Manufacturing is one of the key technologies that allow going beyond the assumptions driving the old acquisition strategies. It provides the following fundamental changes: VM can be used to *"prove out"* the production processes, resulting in *"pre-production hardened systems"* - i.e., the systems which are developed and verified but never actually undergo actual production runs; VM can significantly improve production flexibility, and hence, reduce the fixed costs; and VM can substantially improve the decision making process of acquisition managers by reliably predicting schedule, risks, and costs.

BACKGROUND

According to the Air Force Man Tech *"Virtual Manufacturing is an integrated, synthetic manufacturing environment exercised to enhance all levels of decision and control"* in a manufacturing enterprise [6, 10].

It is clear from the results of the Virtual Manufacturing Workshops organized by Air Force Man Tech [11, 12] that a single definition of VM is inappropriate. A definition of VM is proposed to capture design, production, and control aspects of manufacturing: The Design-Centered VM adds manufacturing information to the Integrated Product and Process Design (IPPD) process with the intent of allowing simulation of many manufacturing alternatives and the creation of many *"soft"* prototypes by *"Manufacturing in the Computer"*. The Production-Centered VM adds simulation capability to manufacturing process models with the purpose of allowing inexpensive, fast evaluation of many processing alternatives. The Control-Centered VM uses machine control models in simulations, the goal of which is process optimization during actual production.

Vision of VM: The vision of Virtual Manufacturing is to provide a capability to *Manufacture in the Computer*. VM will ultimately provide a modeling and simulation environment so powerful that the design, fabrication/assembly of any product including the associated manufacturing processes, can be simulated in the computer. A comparison between the physical and virtual manufacturing is shown in Figure 1.

VM Concepts: VM supports implementation of lean/agile manufacturing to achieve improvements in enterprise flexibility and economy. The use of simulation results in manufacturing systems those are less risky to change. Computer assisted model-based planning and control systems require less coordinating communications.

[1]R. Radharamanan, School of Engineering, Mercer University, 1400 Coleman Avenue, Macon, GA 31207-0001, USA, radharaman_r@mercer.edu

The models provide a basis for sharing knowledge between organizations. VM based systems are expected to enhance operations by providing timely answers to the questions: Can we make the product? What are the alternatives? What is the best way to produce the product? When can we deliver the product? How much will it cost?

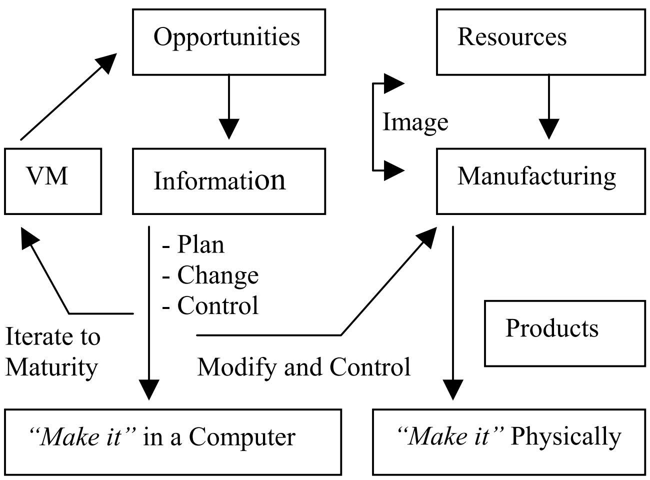

FIGURE. 1
COMPARISON BETWEEN PHYSICAL AND VIRTUAL MANUFACTURING

The relation between the existing enterprise and the market force in creating a new product, the needed changes, the bottlenecks, and the requirements for the new product development are highlighted in Figure 2.

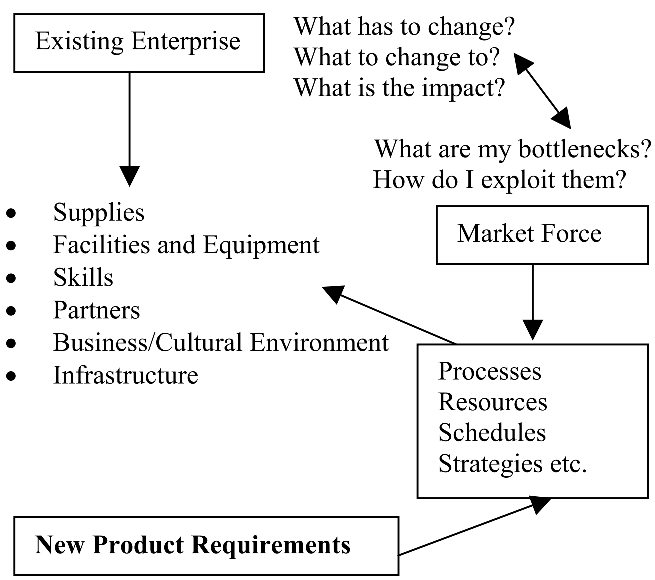

FIGURE. 2
REQUIREMENTS FOR NEW PRODUCT DEVELOPMENT

VM relies on modeling and simulation technology to simulate the production process and to enable us *"make it virtually."* It is an application of modeling and simulation, but extends that discipline beyond the conventional use. VM supplements the IPPD process since it provides a pathway for the manufacturing knowledge to be migrated to the early phases in the life cycle. VM also adds simulation to the Virtual Enterprise (VE) concept and Virtual Prototyping. VM must be integrated with all the relevant enterprise functional areas via a trade-off mechanism (IPPD process) as shown in Figure 3.

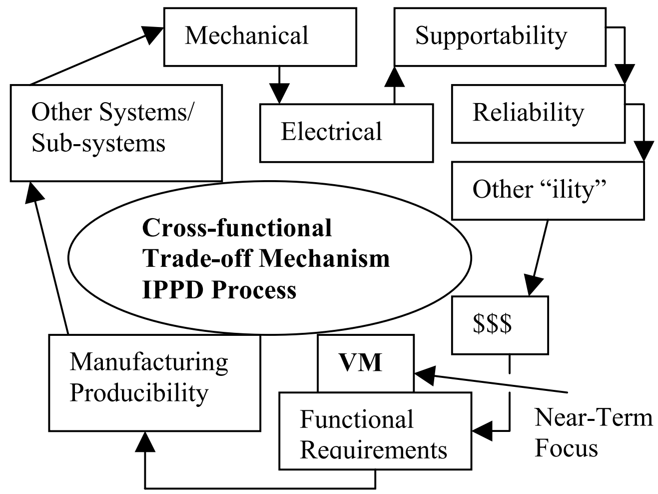

FIGURE. 3
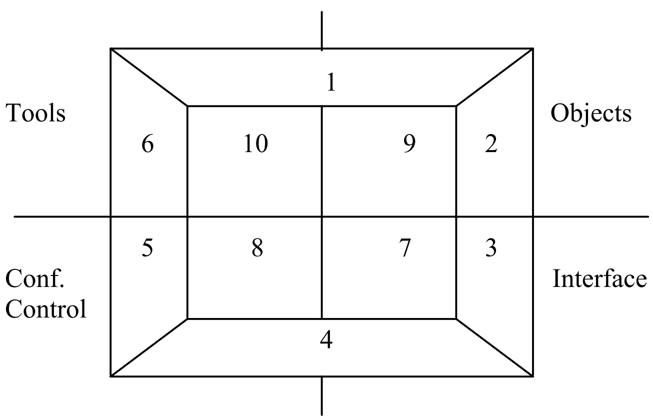
THE INTEGRATION OF VM WITH ENTERPRISE FUNCTIONS

The expected benefits of VM are summarized below: preparedness for market trend, affordability, shorter cycle times, producible prototypes, flexibility, quality, responsiveness, and customer. Virtual Manufacturing as an emerging technology looks for the development of appropriate new tools and techniques for its successful implementation and realization.

Some of the existing tools that can be effectively incorporated for realizing VM include [9]: Design tools, production tools, quality tools, artificial intelligence (AI) tools, computer science tools, management tools and mathematical tools.

The Technical Workshop results indicated that the technologies critical to VM could be organized into the following major categories [12]: Visualization; Environment construction technologies; Modeling technologies; Representation; Meta-modeling; Integrating infrastructure and architecture; Simulation; Methodology; Integration of legacy data; Manufacturing characterization; Verification, validation, and measurement; Workflow; and Cross-functional trades.

VM environment enables a shortening and simplification of the life cycle, by improving the reliability of analyses and accelerating decisions through the use of modeling and simulation. VM helps to evaluate product making using simulation and supports operations to provide timely response to the Integrated Product and Process Design (IPPD) functions in the development of new products and/or processes. Collections of objects in a VM environment may also simulate the entire manufacturing enterprise to provide rapid response to customer requirements. Customers with multiple VM-based supplier organizations can use models of their suppliers' enterprises to provide knowledge to an Enterprise Capabilities Expert. Vertical partners can contribute to capabilities models for use in the knowledge-based computer programs that will evaluate customer requirements and supplier capabilities to establish the organizations desirous of responding to specific customer needs. VM also will support rapid technology transfer by enabling the sharing of the advanced manufacturing capabilities between cooperating organizations. VM applications and VM tools of one organization may be shared by means of the National Information Highway to the operations of manufacturing partners. Some of the specific areas of applications are: corporate memory, capital investment, supplier management, product design, cost estimation, risk management, customer interface, functional interface, and shop floor. The components of VM architecture are shown in Figure 4.



1. Product performance; 2. Process simulation;
3. Producibility simulation; 4. Production control;
5. Supportability, Maintainability, Disposability;
6. Assembly Visualization; 7. Unit & Component Models;
8. Assembly Models; 9. Factory Models; and
10. Enterprise Models.

ARCHITECTURE OF VIRTUAL MANUFACTURING TECHNOLOGY.

RESULTS AND DISCUSSIONS

Based on the literature search to identify the key issues for realizing VM, it can be summarized that new integration technologies and philosophies are emerging. Visualization hardware and software is becoming more affordable and widespread. New modeling and model abstraction techniques are appearing. The most important set of technologies center on modeling and simulation. Some of the key areas that require attention in modeling and simulation are: model object selection (what to model); degree of abstraction; level of depth; flexibility and maintenance of models; integration of different models; and model validation. The results are discussed under the following headings:

Flexible Manufacturing: The discussion with a National Research Group from Oak Ridge National Laboratory, Sandia National Laboratories, and Los Alamos National Laboratories indicated that the research in telerobotics and flexible manufacturing systems though showed progress, it would be practically impossible to totally replace human with robots. Maturity in existing and emerging technologies (both hardware and software) is needed to see potential success in this area.

Lean Manufacturing: Womack et al. [13] in their book on *"The Machine that Changed the World"* addressed the future of the automobile and extensively discussed the importance of lean production. A team spent five years exploring the differences between mass production and lean production in one enormous industry. They have been both insiders with access to vast amounts of proprietary information and daily contact with industry leaders, and outsiders with a broad perspective, often very critical, on existing practices. In this process they have become convinced that the principles of lean production can be applied equally in every industry across the globe and that the conversion to lean production will have profound effect on human society - it will truly change the world.

Virtual Prototyping: The discussion with a rapid prototyping user group revealed that the customers have difficulty is accepting *"Virtual Prototyping"* as one of the means of acquisition for the following reasons: There exists a significant difference in the prototype they see *"virtually in the computer"* and the real product they receive; One can show a colorful, attractive, and high quality products *"virtually in the computer"*; however, the real product may differ in various aspects - including functional and aesthetic aspects - of what was seen in the computer. Virtual Prototyping is still in the experimental stage and it will take a few more years to mature in terms of technology (visualization, representation, abstraction, and appropriate hardware and software) and be used by vendors and consumers.

Virtual Quality: The discussion with the users of TQM, and ISO/QS 9000 showed that virtual manufacturing concepts will aid significantly the way business will be done in the future for the following reasons: Once the VM technologies mature, the concept of building quality in the product is much easier even before the product is made and hence the concept of *"Right First Time"* will have much more meaning in term of Quality Standards. Quality is defined as *"Fitness for Purpose"*, and the VM technologies will make it happen since the customers can make *"changes virtually"* in the product and make it fit for the intended purpose even before the product is made. In terms of quality, VM can go beyond the customer satisfaction and help in achieving Quality Function Deployment (QFD).

Virtual Reality: Despite the enthusiasm surrounding virtual reality (VR), there is a substantial gap between current technology and that needed to bring virtual environments closer to reality. That is the conclusion of a National Research Council committee report on 3D computer-generated worlds with which people can interact. According to the committee, certain areas hold the most promise for practical uses of VR: training, hazardous operations, medicine and health care, design, manufacturing, and marketing. Using VR and telerobotics, one can or will be able to explore the ocean floor and outer space, dig up a 10-ton container of hazardous waste, take a submarine trip through the human circulatory system, and try out products not yet manufactured, for example.

Virtual Organization and Agile Manufacturing: In the search for agility, companies will rely increasingly on virtual enterprises, virtual manufacturing, and virtual reality. Goals of virtual manufacturing include analyzing design, product, and process alternatives for viability, cost and risk; integrating product and process development; improving customer response time and cost estimates; and retaining corporate knowledge. The Society of Manufacturing Engineering developed a videotape on *"Agile Manufacturing: Moving to the Next Level"* [1]. The video addressed *"agility"* as the new survival concept for global manufacturing competitiveness and indicated that the emerging concept of agility is based on the factors: markets of all nations are combining into a single global economy; rapid change in the global market place is inevitable; the explosion of technology makes every country a potential competitor; customers are demanding customized products with short lead times. Goldman et al., [3] in their book on *"Agile Competitors and Virtual Organization: Strategies for Enriching the Customer"* addressed how to confront and thrive on change and uncertainty.

Realization of VM: The STEP standard [5] is intended for long-term development and uses a widely available language called Express to describe the complexities of solid geometry. STEP, also referred to as ISO-10303, is an international standard for the exchange of product model data. Designers and engineers should be aware of its capabilities, how it might be used, and what developers have planned for it. The super-model database, in progress, will be Web compatible and it can be accessed by the entire supply chain. The Web based languages such as SGML (Standard Generalized Markup Language), HTML (Hyper Text Markup Language), and XML (eXtensible Markup Language) are helpful in implementing VM. SMMS software [4] developed by RTSe (USA), Inc., is an ideal product for creating, managing, and publishing metadata to improve overall management of large data archives. SMMS can also be used in the realization of VM.

Research Relevant to VM: The Virtual Manufacturing Technical Workshop [12] identified technologies that are critical to virtual manufacturing. The technologies were classified under Core Technology, Enabling Technology, Show Stopper Technology, and Common Technology. The Core Technologies identified and reported are: VM methodology for process characterization; technologies to simulate assembly operations; declarative representation of product and processes; natural language for VM meta-model; cost database and integration; VM user interface (communication between VM knowledge base and user); VM verification & validation methods, algorithms & tools; process model and simulation validation; methodology for using a VM system; VM framework (guidelines, integration standards, etc.); methodology for design abstraction; tools to relate conceptual design with possible manufacturing methods and processes and cost estimates based on manufacturing features; manufacturing engineering automation (knowledge-based computer applications to perform manufacturing engineering decision making); and simulation architecture.

It is seen that some of the technologies listed above and other related technologies are being studied by government agencies, academia, and industry in the U.S. and other nations. It is necessary to coordinate and bridge the gaps in randomly emerging technologies related to VM and mature them. Some of the technologies that need immediate attention are: selective addition to animation, shop floor based generic models, metrics, representation, and integration.

VM CONCEPTS IN ENGINEERING EDUCATION

The increasing access to Internet and the World Wide Web has expanded the variety of media by which universities are able to offer distance learning opportunities. Most recently courses and whole degree programs are being developed for delivery via the Internet.

Online students have many advantages as well as disadvantages compared to traditional and other forms of distance education. The advantages include: More accessible to mature students; Gteater flexibility to control the time, pace and order in which to study the course materials. The disadvantages are: Removes the structure providesd by weekly class meetings; Less disciplined students can easily fall behind in the class work; No motivation, support and encouragement from the instructor; No help and mentoring from the faculty; Do not allow students to see the instructor deliver the lecture and respond to students' questions like in televised or video formats; and Possibility of higher dropout rate. These disadvantage are likely to have adverse effect on student performance.

The collaborative learning environment enhances student learning and performance by taking advantages of Web-based technologies. Web-based materials can be classified in different categories: course administration, reference textbooks, lectures, laboratory simulation and experiments, and recitation/assignments/grading. Common information provided consists of items such as teaching schedules, the syllabi, instructor's contact information, list of assignments, grades, links to other sites, and basic lecture notes. These sites do not take advantage of the interactive capabilities of the delivery medium, as the Web is only used as an efficient repository of information. An important component in the collaborative learning paradigm is the use of Virtual Portfolios. The major difference between the virtual portfolios and traditional ones are that virtual portfolios are on-line for anyone to evaluate and that they remain on-line for years to come, allowing students to take advantage of these resources and marketing tools during their job searching activities. Inter-group peer evaluations transfer some of the responsibility of the assessment process to the students, thus, promoting critical learning by requiring students to compare, evaluate and reflect upon their own work and that of others. Students can also be tested through web-based readiness assessment quizzes.

Virtual reality concepts are to redesign the introductory mechanical engineering course in an effort to incorporate the learner as designer strategy, and positively impact the students' conceptual understanding. To achieve these objectives, the courses were designed to use virtual reality as a tool that integrates the fundamental concepts of design, analysis, and manufacturing. Further, virtual reality is used to create an arena for constructivism, interactive learning and experimentation with design [7]. Dessouky et al [2] proposed a Virtual Factory Teaching System (VFTS) in support of manufacturing education – i.e., a multimedia collaborative learning network that illustrates the concepts of factory management and design in a realistic setting. To assess the viability of a VFTS for manufacturing education, a prototype was developed that aids the students in learning a specific manufacturing topic, factory scheduling.

CONCLUSIONS

The potential scope of VM is very large. What is important is that a time phased, realizable scope for VM be defined. VM should be implemented incrementally starting at unit product/process level, then at subsystem level, and finally at system level. The manufacturing process and the scope of VM products should be improved in the *"big M"* manufacturing domain: concept through production including marketing, sales, and service. Disagreement remains on what VM is and the key issues for realizing VM - there is a need to define VM more precisely. VM concepts and web-based tools are effectively being used in engineering education for training, distance learning, laboratory education, and testing of students. Some of the other VM concepts/tools such as virtual prototyping, virtual quality, virtual laboratory, virtual factory system, and modeling and simulation technology are being tested for effective use in engineering education.

ESTILO DE APRENDIZAGEM: UM INSTRUMENTO NO ENSINO DE ENGENHARIA

Anna Cristina B. D. de Carvalho[1] and Arthur José Vieira Porto [2]

Abstract — *The engineering students are not different from other students. Each one of them learns in a different way. That heterogeneity can harm the learning in a classroom, because depending in the way as the teacher leads your classroom. To know the style of learning of the students help the teacher to plan your classes in a more appropriate way and more it holds.*

The use of the inventory of learning styles is a tool developed by David Kolb that identifies the style of the individuals' learning. She can be used to help the teacher to understand better as your students they learn and to plan the form of developing the contents in classroom.

The present work has as objective presents a study on the use of the inventory of styles in the planning of the engineering teaching.

Index Terms: Learning, Engineering, Style

INTRODUÇÃO

A nova Lei de Diretrizes e Bases publicada em 1996 orienta o ensino superior no Brasil. Ela define que o profissional de engenharia deve ter formação técnico científica sólida capaz de aprender e desenvolver novas tecnologias, ter uma atuação criativa e crítica na identificação e resolução de problemas de diversas naturezas.

Essa formação citada pela nova LDB[1] sugere que os cursos de engenharia precisam passar por um processo de mudanças em suas estruturas, pois não se desenvolve criatividade e atuação crítica apenas com a formação seqüencial de disciplinas que ensinam regras de cálculo para os alunos. Além disso, existem os problemas de aprendizado que envolve professores e alunos. Os professores são responsáveis pela mediação do conhecimento e os alunos pela busca de novos saberes.

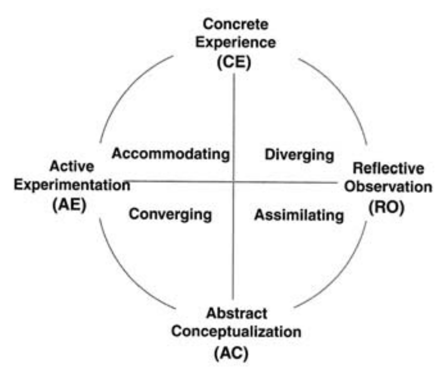
A identificação do estilo de aprendizagem do aluno é um dos requisitos para a melhoria do processo ensino/aprendizagem. O estilo de aprendizagem é a forma como o aluno aprende melhor. Identificado o perfil da turma o professor poderá preparar atividades adequadas ao conteúdo que vai ser desenvolvido.

O objetivo desse trabalho é apresentar um instrumento fácil de ser utilizado pelo professor em seu planejamento de sala de aula privilegiando o uso de tecnologias, discussões, estudos de casos e outras ferramentas importantes do desempenho do aluno.

INVENTÁRIO DE ESTILOS

O inventário de estilos foi desenvolvido por David Kolb com a finalidade de identificar os estilos de aprendizagem de seus alunos. As indagações de como se aprende melhor, por que existem ritmos diferentes de aprendizado, motivaram Kolb a estudar e desenvolver um instrumento de auxílio a identificação do estilo de aprendizagem.Ele observou que existiam formas de perceber o conhecimento e de processar o conhecimento. As formas observadas por Kolb inicialmente foram: Experiências concretas, observação reflexiva, conceituação abstrata e a experimentação ativa.

O inventario de estilos de aprendizagem consiste na



identificação das preferências do indivíduo no processo de aprendizagem. Essa identificação é feita de duas formas, através da percepção dos fatos e do processamento desses fatos. A figura 1 mostra os quadrantes contendo os estilos de aprendizagem.

[1] Anna Cristina B. D. de Carvalho, University of Fortaleza, Rua Washington Soares,1321, CCT, 60811-341, Fortaleza, CE, , Brazil, annacbdc@bol.com.br
[2] Arthur José Vieira Porto, University of São Paulo, Av. do Trabalhador São Carlense, 400, 13566-590, São Carlos, SP, Brazil, ajvporto@sc.usp.br

FIGURA 1
Estilos de Aprendizagem (Kolb,[2])

Os estilos podem são caracterizados a seguir:

- **Divergente** – se encontra no primeiro quadrante, tendo como preferência de percepção as habilidades ligadas a experiências já observadas e processam o conhecimento através da reflexão das observações feitas. Pessoas com este estilo não concordam com soluções convencionais, buscam sempre novas alternativas. Eles aprendem melhor em situações que possuem generalização de idéias. São pessoas com imaginação fértil, se preocupam como bem estar dos outros, utilizam seus sentimentos para tomar decisões, gostam de cultura e arte, são chamados divergentes por serem individualistas e buscam sempre alternativas pessoais de melhoria;
- **Assimilador** – Eles associam observações feitas de situações com conhecimentos que já adquiriram. São muito teóricos, necessitam de conceitos teóricos para embasar as observações feitas. Não são muito intuitivos, são lógicos e não tem interesse em desenvolver relacionamento interpessoais. Não aceitam fatos que não podem ser provados teoricamente. Esse estilo é chamado de assimilador por estar sempre em busca de novos conhecimentos;
- **Convergentes** – São aqueles que integram a teoria e a prática. Utilizam tanto a teoria como o senso comum. Gostam de resolver problemas práticos. Utilizam as hipóteses para definir solução de problemas. São chamados de convergentes por buscarem soluções ótimas para problemas práticos. São muito práticos;
- **Adaptáveis** (no original seria accommodating**)** – são muito interessados em fazer coisas, levar planos a frente, fazer experiências, viver o novo. Não tem medo de riscos. Normalmente resolvem problemas na forma de tentativa e erro. Utilizam outras pessoas para encontrar a teoria que possa ajuda-lo na situação que precisa resolver. São pessoas muito criativas e inquietas. Descobrem novas teorias sem precisar de uma orientação padronizada. São naturalmente lideres. São chamados de adaptável por se adaptarem muito fácil a novas experiências e situações;

Para identificar o estilo de aprendizagem, o professor aplica um questionário contendo perguntas que se relacionam com a forma como aluno aprende melhor. O aluno responderá conforme seu grau de preferência. Depois de respondido são somados os pontos das questões correspondentes a cada estilo e colocado no gráfico apresentado na figura 1. Nesse gráfico é visualizado qual o estilo é mais marcante no aluno.

Com esses dados o professor pode perceber a preferência dos alunos e fazer seu planejamento de aula com ferramentas que auxiliem o aluno a aprender melhor.

CICLO DA APRENDIZAGEM

Podemos definir o ciclo da aprendizagem como o processo pelo qual passa o indivíduo para consolidar os conhecimentos novos que serão acrescentados a sua estrutura cognitiva.Existem vários autores que estudam o ciclo da aprendizagem o que foi utilizado como base teoria foi o ciclo de Belhot, que possui as mesmas características dos outros ciclos, mas tem uma influência construtivista. A figura 2 representa todas as etapas do ciclo de aprendizagem de Belhot.

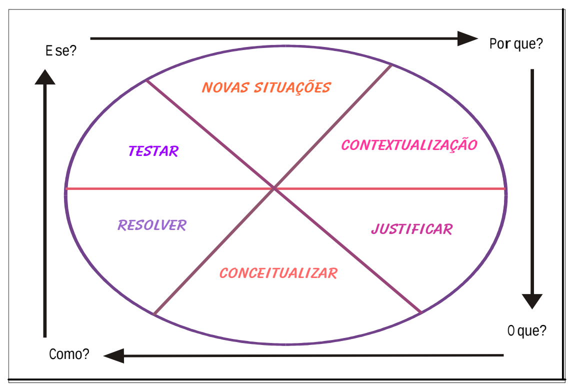


FIGURA 2
Ciclo adaptado de Belhot [3]

A primeira etapa desse ciclo é o questionamento, a busca dos por que? E da busca de relações com o que se pretende entender. Essa fase é muito importante, pois o indivíduo é despertado para um novo conhecimento. Ele começa a se envolver com as dúvidas e as questões não resolvidas sobre o assunto. È uma fase de observação.

Segundo Belhot [3], é nessa fase que ocorre a descoberta do sentido do assunto e a motivação para aprender. Todas as atividades que envolvam o desafio da descoberta são bem vinda. O aluno tem a oportunidade de expor aquilo que não sabe e levantar questões que se relacionam com o assunto, mas que ele não conhece.

A segunda fase faz parte do processo de observação. È nela que se levanta o que é mais importante ser aprendido. O que realmente interessa para aquele assunto. Nessa fase o professor começa a expor o conhecimento. A dividir com os alunos os pontos importantes do assunto e chamar a atenção dos mesmos a partir de suas dúvidas listadas na fase anterior. A grande motivação dessa fase deve ser a necessidade de resolver as dúvidas anteriores e aprender coisas novas sobre o assunto. Inicia-se uma fase onde o aluno vai começar a assimilar novos conceitos e ancorar esses novos conceitos a conceitos pré-existentes.

A terceira fase do ciclo que também faz parte da assimilação é como aplicar esses conceitos nas atividades reais. Como tornar esse conceito utilizável no dia-a-dia. Essa é a etapa em que o professor vai apresentar exemplos, exercícios, estudos de casos para que o aluno sinta-se seguro para aplicar o conceito novo e ampliar ainda mais o universo que se iniciou com a apresentação de dúvidas sobre um determinado assunto. Nessa etapa o aluno entra em contato com ferramentas e técnicas que podem facilitar seu processo de desenvolvimento. O computador é uma excelente ferramenta nessa etapa. (Belhot, [3]).

A partir da fase anterior começa a etapa do fazer, onde os alunos começam a levantar novas hipóteses de uso do conhecimento. Com mais maturidade fica tranqüila levantar situações diferentes e tentar resolver essas situações. Aqui não existe mais regra fixa para facilitar a execução de uma atividade que envolva o conceito aprendido. O aluno começa a aprimorar o conhecimento e a levantar alternativas diferentes para resolver os obstáculos que vão aparecendo ao longo da nova situação.

Para que esse processo gere novos conhecimentos é necessário que o assunto esteja bem dividido e hierquizado, evitando assim, erros na formação da estrutura cognitiva do aluno. Além de ajudar o aluno a formar sua própria estrutura de conceito, facilitando a busca de novos conceitos. Para se obter um resultado positivo é necessário que o aluno seja motivado, sinta-se seguro e outros aspectos apresentados anteriormente na teoria cognitivista.

PROCESSO DE PLANEJAMENTO

O planejamento de aula é necessário para que o professor identifique os objetivos as serem atingidos, os conceitos importantes, as atividades complementares e a tecnologia educacional que deve ser utilizada. As etapas para desenvolvimento desse planejamento são(Carvalho[4]):

1. Definição das competências a serem desenvolvidas na disciplina;
2. Definir os conhecimentos necessários para o desenvolvimento dessas competências;
3. Aplicar os conteúdos no ciclo da aprendizagem para identificar as tecnologias que poderiam ajudar em cada item;
4. Identificação do estilo de aprendizagem dos alunos e fazer adaptação das técnicas planejadas se necessário;
5. Fazer avaliações periódicas para verificação dos alvos estabelecidos;

A primeira e a segunda etapa do planejamento é a identificação das competências que serão desenvolvidas através dos conteúdos que serão apresentados aos alunos. Segundo Perrenoud [5] a noção de competência remete a situações nas quais é preciso tomar decisões e resolver problemas. A competência utiliza conhecimentos e capacidades, mas só consegue ser desenvolvida quando a ação se realiza. Não são somente conteúdos que serão apresentado aos alunos, mas situações reais ou que simulem a realidade para ajuda-los a desenvolver essas competências.

A terceira etapa do planejamento é adequar tecnologias educacionais ou atividades complementares a cada um dos conteúdos que serão desenvolvidos. Para isso o professor precisa conhecer o ciclo da aprendizagem e os estilos de aprendizagem para entender qual o melhor instrumento em cada conteúdo a ser apresentado. A figura 3 mostra o ciclo da aprendizagem com os estilos de aprendizagem e as possíveis tecnologias que poderão ser utilizadas pelos professores.

A quarta etapa o professor verifica o estilo de aprendizagem dos alunos no início do curso e verifica se as atividades planejadas estão adequadas, caso não estejam pode ser feito uma adaptação para que o resultado do aprendizado possa ser o esperado.

A quinta etapa é avaliações com os alunos, não somente avaliações de conteúdo, mas qualitativas para verificar a eficiência das atividades planejadas. Os alunos são um ótimo termômetro para verificação da eficiência de atividades em sala de aula.

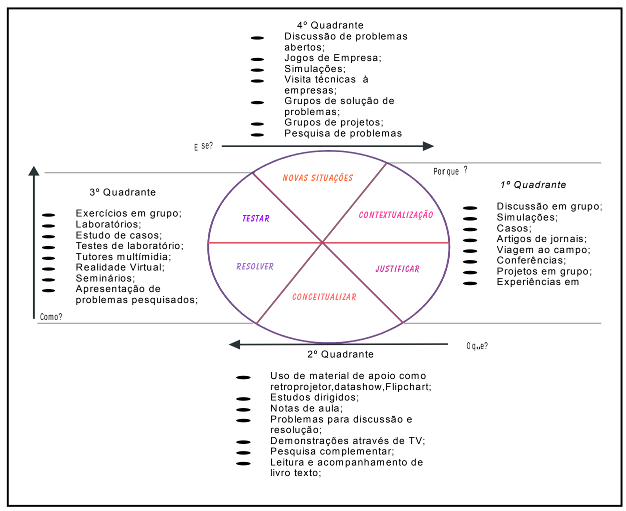

FIGURA 3
Ciclo de Belhot modificado por Carvalho [4]

CONSIDERAÇÕES FINAIS

Os professores de engenharia podem utilizar a metodologia acima, sem dificuldades. Ela é simples de ser entendida e de ser utilizada.

Os conhecimentos sobre ciclo da aprendizagem, novas tecnologias, estilo de ensino ajudam o professor a preparar um planejamento de aula mais rico e consistente. Esse procedimento necessita que o professor esteja sempre atento as reações dos alunos em sala, pois qualquer tendência de falha no processo de aprendizagem pode ser verificado o problema e corrigido.

Os professores de engenharia estão passando por atualizações e modificações em seus comportamentos diante da função de educador. É importante não somente formar profissionais aptos ao desenvolvimento de cálculos complexos, mas aptos à análise e modificações de situações problemas.

O desenvolvimento desse trabalho teve por finalidade auxiliar os professores na melhoria de suas atividades em sala de aula.

A TEACHING AND LEARNING ENVIRONMENT FOR INTEGRATING VIRTUAL LABORATORIES

José Manoel de Seixas[1], Carmen Maidantchik[2], Rômulo Cunha Monteiro[3] and Gustavo Luis Almeida de Carvalho[4]

Abstract — *In this work, a teaching and learning environment to support different virtual engineering laboratories is described, allowing remote access via Internet. Such environment integrates virtual laboratories on linear systems, signal processing, control engineering, and neural processing and it is designed to be used in continuous learning and regular undergraduate courses, both in the frameworks of presential and distance learning programmes. As the laboratories are designed in a modular structure and using accessing layers of different depths of the didactic material, extensions to accommodate other virtual laboratories can be easily accomplished. The environment also supports implementation in firmware, using digital signal processor technology. A set of tools integrated to the environment also supports the automatic introduction of new modules by the teachers and communication among students and between students and instructors.*

Index Terms — *Distance learning, engineering education, remote and virtual laboratories.*

INTRODUCTION

The Internet and recent computing resources offer many possibilities for disseminating educational material to students, both locally and as part of remote programmes. Traditional courses offer classes driven by professors, and supported by libraries, exercising lists and hours dedicated to the clarification of misunderstandings and doubts. Uncertainties of previous years can reamain the same for new students. Therefore, the answers of earlier doubts can be helpful for novices as well and accomplished projects can serve as a base for new developments. Failed experiences can be analyzed and understood to avoid undesired outcomes. Graduated students can access stored materials to improve the way a task is planned, designed, implemented, tested, adapted, expanded and so on. Furthermore, one working team can make use of all information and acquired knowledge of other groups, not necessarily in the same domain area.

Within a worldwide scenario, the Internet is a powerful tool to provide access to any data independently of its location and of person's background. So, knowledge databases are becoming increasingly popular as a method to catalog the best practices of several categories of projects and keeping, in this way, the main resource that an enterprise has, it means, its experience.

Engineering projects are becoming more and more complex because they are involving interdisciplinary and cooperative activities and some working group members are geographically distributed, placed at different locations. Another arising necessity is that laboratory experiments are a vital part of engineering education [1]. Recent advances in Internet/Web technologies and computer-controlled instrumentation presently permit net-based techniques to be utilized for setting up environments that respect the previous requirements. In this context, teaching and learning activities have been requesting urgent reviews on traditional educational systems, in order to match the needs of modern communication models [2].

In this paper, we present an Internet teaching and learning environment to support different engineering virtual laboratories. It integrates hypertext pages on linear systems, signal processing, control engineering, and neural processing. The laboratories are designed for either continuous learning or regular undergraduate courses. Their modularity facilitates the integration of diverse virtual building blocks and allows the aggregation of new material. The environment also supports implementation in firmware, using digital signal processor (DSP) technology. A set of tools integrated to the environment also supports the various aspects of engineering classes and learning processes, such as, for instance, the communication among students and between students and teachers.

VIRTUAL ENGINEERING LABORATORIES

The Federal University of Rio de Janeiro has been developing the Papoula Project, envisaging the interconnectiont of virtual laboratories. The project aims at furnishing a learning environment that integrates a set of virtual hypertext labs, in a way to explore new teaching approaches and to introduce sophisticated technologies. One of the fundamentals of the proposed environment is the hardware and software amalgamation, which is in fact a strong observed tendency in engineering nowadays. It is important to realize that such concept of fuzzy limits between hardware and software emphasizes how broad is the knowledge required in the conception and elaboration of modern engineering projects.

More specifically, the integration of virtual laboratories is achieved by hypertext links that are set among the contents of each individual module belonging to the interconnection net. Three development layers

[1] José Manoel de Seixas, COPPE/EE, Federal University of Rio de Janeiro, CP 68504, 21945-970, Rio de Janeiro, RJ, Brazil, seixas@lps.ufrj.br
[2] Carmen Maidantchik, COPPE, Federal University of Rio de Janeiro, CP 68504, 21945-970, Rio de Janeiro, RJ, Brazil, lodi@lps.ufrj.br
[3] Rômulo Cunha Monteiro, EE, Federal University of Rio de Janeiro, CP 68504, 21945-970, Rio de Janeiro, RJ, Brazil, rcunha@lps.ufrj.br
[4] Gustavo Luis Almeida de Carvalho, EE, Federal University of Rio de Janeiro, CP 68504, 21945-970, Rio de Janeiro, RJ, Brazil, glac@lps.ufrj.br

compose the elaboration method of the contents of each module of each virtual lab. The first layer aims at facilitating the knowledge acquisition by the student of fundamental topics of each module. The second layer is dedicated to the simulation of the topics that will be further codified into hardware (firmware), in a way that the student can explore a practical implementation. Thus, the last layer, provides the virtual access to hardware implementation over programmable devices, in this case, using the digital signal processing (DSP) technology. The layers are implemented through commercial and widely used software packages, which allows students to easily enter into the lab environment.

The implementation of the hardware layer is performed by experiments built over a computer net, using testbench equipments (generators, power-supplies, oscilloscopes, multimeters), which are remotely commanded through the Web. The equipments are interconnected by a GPIB interface, which allows the communication with the server computer of the environment. A virtual instrument for each piece of equipment is thus available to the users for control and display of the experiments. In the server, a DSP development layer is installed, which makes it remotely accessible. This proposal gives priority to a fast, easy and dynamical communication through a suitable language at each interaction level in order to stimulate the students [3].

This model for the learning and teaching environment can support both regular and distance learning programs. It also integrates available information technology in order to facilitate not only who accesses the didactic material but also who creates the virtual laboratories. The distinction of the Papoula Project, comparing it to other distance learning developing environments, is the grouping of diverse engineering subjects and tools within a cooperative environment, offering a remote execution of resources and allowing their sharing. It is interesting to notice that this model can also be applied in other contexts, such as cooperative work, resources training and experiments through virtual instruments.

Before initiating the construction of a distance learning environment, as the initial investment is quite high, even when having the supporting tools available, it is important to validate its real need, since a traditional class or a presential training can be less expensive. The first step is to validate whether the content will have some stability. Evidently, the content of a distance learning course can be updated, but it is necessary to consider the costs of its maintenance. A remote course can be synchronous with a specific date to start with and predefined length, offering discussion means, hardware access (the technical responsible or even a sort of robot has to turn it on and off) and cooperative tasks. A registering tool is essential in such cases. On the other hand, a distance learning course can also be asynchronous and, in these cases, the students must to have in mind that arising doubts sent by email may not be answered immediately [4].

In order to make the developing process of distance learning environments easier, some steps must be respected: define who are the main users, study the need of different access form for all types of users, define the fundamental requirements to provide ways of using the learning tool, inform the whole contents of the material to alert users before initiating the course, define a plan of a suitable navigation to avoid that wrong choices influence the learning process.

The development of a Web-based learning tool must give priority to the interactivity and to the communication among students and between an educator and students. Pointing towards this goal, the environment should dispose some services such as forums, notes about the course, main topics and bibliographic references used. The user registration tool is a powerful tool, since it enables the information exchange among users and serves as a base for the environment that can provide a suitable configuration according to students' background. A student register helps on determining the user profile through an analysis of his/her data stored into a database. In conjunction with other tools, a distance learning course may personalize the page navigation, automatically switching the contents to the needs or to the skills of its users. It is important to take into consideration that everybody, including those with no Web experience, has to be able to use the tools and the learning environment itself. In this way, the environment could offer Web tutorials in order that more complex functionalities could be used in the advanced modules.

DISTANCE LEARNING TOOLS

At the beginning of the developing process of a supporting tool for a distance learning environment, some steps should be followed as describing its goal, defining the input and output data, classifying its functionalities, identifying the development strategy, restrictions and improvements for a next version. This specification guides programmers as it delineates the tool scope and target.

Within the Papoula Project, the tool organization follows the classification proposed by Malluhi [5]:

- **System administration tools:** belong to this group the tools that make the user interface to work, including its facilities such as password protection, user's files access, user profile characterization, dynamic menu automatically generated, contents listing in a linear format (not in a hypertext format), user registration including access levels based on the student knowledge, mechanisms that allow access level change, localization in the hypertext map, specialization, map of the site, automatically update of the references, and verification of not existing hypertext links.
- **Authorizing supporting tools:** any implementation that supports the structuring of a distance learning course can be classified in this category: selection of course components from a complete list, contents publishing based on certain criteria, multimedia contents, test and examination creation, graphical page design, personalized icons, course outline elaboration support, last updates, glossary access, mechanism for searching and inserting hypertext

links, sensitive figure generation, cooperative authoring, references list, working team (titles, background and positions) and general information about the course.

- **Collaboration and communication tools:** belong to this group the tools that assist the instructors on controlling ongoing courses as visualization of the entire course by instructors, visit counting, statistics of the time spent in each module, activities registry, frequency control, examination and listing databases, test generators, automatic correction of tests, creation of groups, advertisements, and administration of users.
- **Students tools:** implementations that support users to visualize the contents and to obtain information about its performance such as grade visualization, comparison between a certain grade and the class average, creation of lesson guides, abstract database, searching for a specific data within a course, presentation of the latest modifications, and glossary of terms.
- **Virtual and remote laboratory tools:** this category groups all tools that support simulations (virtual labs) or the remote execution of resources as software and hardware supporting mechanisms and mathematical function programs.

In the context of the proposed environment, the tool development is directly related to the technological needs of the virtual laboratories.

PAPOULA: AN IMPLEMENTATION OF THE PROPOSED MODEL

The PAPOULA[5] environment corresponds to a practical accomplishment of the proposed model. It runs on the Web and its main goal is the delivery of a set of laboratories on the Internet that supports the learning of some of the main subjects in electronics engineering. PAPOULA offers to the users three levels of contents and exercises, both theoretical and practical, as well as a virtual practice of experiments with the support of a specific software for either a simulation of a device or a real hardware test through remote mechanisms. The current laboratories already implemented and linked are:

- **PATROL:** supporting pages to the learning of control systems, including aspects of both classical and modern control engineering.
- **PAPROS:** supporting pages to the learning of signal processing, presenting the main topics in signal processing, discrete and continuous.
- **PANN:** supporting pages to the learning of neural networks under supervised and unsupervised learning.
- **PALAS:** supporting pages to the learning of linear systems, including both time and frequency analysis.

[5] The acronym comes from the original in Portuguese, which translation means "supporting pages to presential and distance learning courses".

Besides the contents of the above pages, the Web environment also integrates some of the tools cited in the previous section with the assistance of the "Tools Module", which contains pages to support the technical development of learning systems in the Internet. This module also provides mechanisms to help on the construction of virtual and remote experiences, linked to devices that are shared among several users. In addition, two labs are under development, linking engineering and basic science:

- **PACUS:** supporting pages to the learning of Calculus.
- **PALIN:** supporting pages to the learning of linear algebra.

Figure 1 presents the HomePage of the PAPOULA Web environment. The right frame provides access to the laboratories. The left frame presents the menu, where the main functionality and links are. All pages follow this design, in order to provide the same navigation structure among the accessible laboratories.

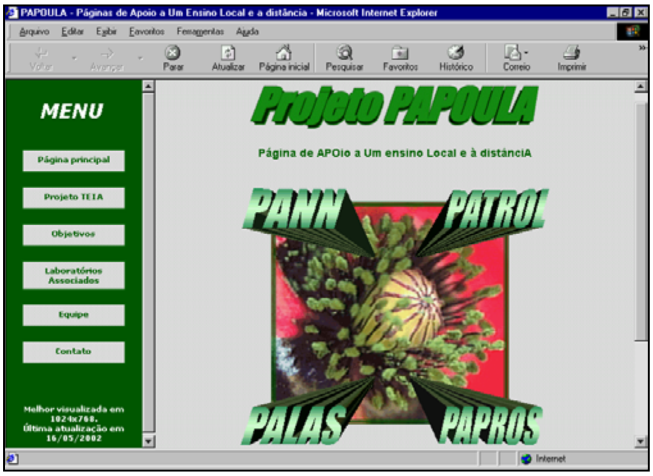

FIGURE. 1

THE PAPOULA HOMEPAGE.

The linked pages through the PAPOULA HomePage have the objective of providing information, via a simple and informal way, of the subjects discussed inside a classroom. In order to achieve the target of presenting a colloquial text, the students themselves read, understand a specific topic and write the contents with the orientation and supervision of full professors.

The laboratories have to work mainly as an extra helping source to clarify eventual doubts. The practical examples evolve through three stages. In the first stage, exercises are suggested to practice the theory. Succeeding, simulated experiences are proposed. Finally, real experiments are remotely performed with the support of instructors and current technologies. For example, regarding the linear systems theory, the PALAS laboratory integrates simulation techniques of circuits and systems with simple hardware modules. Besides simulation, students can experimentally practice through experimental kits located in one physical laboratory.

As part of the theoretical material, supporting tools to the learning process are accessible by the environment. On each module of a given laboratory, students are invited to face a challenge. A complex problem referred to the current module is presented and, in this way, the subject can be deeper discussed based on the student ability. The challenging section is also useful to test the contents assimilation by students and the creative capacity of a student, as the problem is not directly argued within the module. Obviously, electronic mail supports the communication among students and offers an efficient way to clarify eventual doubts with the assistance of instructors.

Within this environment, the students can access several static data related to the subject (as reading a book) and also interactive contents. The importance of the Web technology in the learning process is the possibility to offer a high degree of interactivity to an user, independently of the working place. It is not demanded to install software or to have a specific hardware. A browser and an Internet connection are enough to start acquiring knowledge and expertise. Though an environment like this, it is possible to perform experiences on numeric simulation through the Web and get the results immediately afterwards. Moreover, the student can choose the parameters that will be used in the simulation.

The pages run over an HTTP Apache server in a Linux platform. The HTML language is used on the static parts of the laboratories and CGI programs, implemented in C or C++ language, correspond to the dynamic part. Graphical results as well as all kinds of images are presented together with the text, contributing to a better understanding of the users through multimedia facilities.

Respecting the informal way of learning, a laboratory can provide "tips" on how using the features, devices and software packages. Another feature is the reference page with hypertext links to other Web sites related to the main subject of the module.

FUTURE IMPROVEMENTS

The working group is developing a Web environment to support the automatic creation of distance learning sites. This feature integrates the contents with only some of the distance learning tools as registry, search by keyword, communication features, latest updates, self-scoring, multiple-choice tests. The Web environment also guides instructors on the requirements of a distance learning environment. It means that the environment asks for important data to be displayed as the author background, the summary of the whole contents, terminology, creation date, objective of the course, an email for contact and so on. Contents and tools are automatically integrated through a database without requiring from instructors knowledge about HTML, JavaScript or Web programming.

Our next step is to develop more pages within PAPOULA by using the Web environment and, in this way, guaranteeing standard interfaces. We also plan to construct other distance learning tools according to the classification presented in this paper. Other important feature is related to evaluative criteria for Web sites that would check aspects related to authority, accuracy, currency, navigation, design, quality of writing and so one [6]. At last, we notice that it is very important to produce a variety of mechanisms to facilitate the creation of virtual and remote experiences.

Regarding the concepts of the proposed model, it is necessary to improve the connectivity method that links the laboratories. Nowadays, the authors have to set each link between two pages. Nevertheless, a certain level of procedure automatizing can be achieved by, for example, the glossary tool, where the terminology of all modules is placed. It could also be very useful to provide a database of content links among various pages and, moreover, a database of experience links among different laboratories.

The idea is to offer a technological "factory" of distance learning pages and to make the construction the most automatic as possible. Professors would concentrate on the contents while the Web environment automatically publishes an already integrated learning material of software, hardware, theory and practice in the Internet.

CONCLUSIONS

The information technology and the intense use of the Internet are becoming very interesting for educators in several knowledge areas. Different conceptions of learning environment on the Web were developed. Nevertheless, the need of creating educational tools that facilitates a fast and easy access to a stored knowledge is increasing, maily due to the necessity of a constant intellectual update.

Generally, the available time that professionals can dedicate to the update of new methods and techniques is quite restricting. Thus, offering conditions to acquire information through a fast and efficient way is essential to either enterprises that need to keep themselves market competitive or qualified peope that constantly need to keep informed.

Recent researches pointed out the potentiality of distance learning through computational support. That is the main reason a specialized distance learning model can contribute to the increasingly grow of new learning methods based on modern technologies applied to engineering courses.

The research project presented in this article intends to construct a multidisciplinary network of virtual laboratories. The network integrates hardware and software to support students in the learning process of different subjects from electronics engineering and basic sciences.

The hypertext pages aim at presenting, through a clear and objective way, material and mechanisms for an effective learning. The Web environment assists instructors within classrooms and not only, as the learning process can be continued out of teaching hours and anywhere. The focus of our proposal is on interconnectivity of data from several domain areas, high interactivity and stimulating the cooperation among users. The PAPOULA environment demonstrates that the proposed model for the interconnection network of virtual laboratories feasible and that students can get more involved with interactive and dynamic learning material.

The integration of tools, contents and devices to connect different virtual laboratories aims at enlarging the navigability about the didactical material gathered by hypertext links constructing a huge net of knowledge.

ACKNOWLEDGMENT

The authors would like to thank FAPERJ (Carlos Chagas Filho Foundation for the Support to the Research of the Rio de Janeiro State) and CNPq (Brazilian Research Council) for their continuous support to this project.

BASIC AND TECHNICAL SCIENCES INTEGRATION IN TERMS OF THE LECTURES COURSE "ENGINEERING CREATIVENESS BASE"

Tatiana M. Tkacheva, Zoya S. Sazonova and Nina V. Chechetkina

Abstract — **Lectures course "Engineering Creativeness Base" is one of very important fundamental disciplines for engineer's training in the State Technical University MADI. This course appears to be syntheses of basic (Physics, Chemistry, Mathematics) and technical disciplines (Material Science, Strength of Materials, Engineering Graphics) and makes students to learn them more and allows students to grasp deeper the significance of their future job and it allows them to feel creative work satisfaction. Learning the course "Engineering Creativeness Base" After learning of this discipline students can better perceive other disciplines necessary to become a real ENGINEER.**

Index Terms — **Philosophy, history, Natural Science, classic Physics, quantum Physics, Chemistry, Biology, Synergy, Ecology, Evolution**

I. INTRODUCTION

In the 20th Century the basic feature of our own period were formed and they can be determined as following: snowballing increase of information, vigorous growth of computer science and using it everywhere, a competition increase of intellectual labor, formation and development of new branches of science, technics and technology. That is why the engineer's background changes and new requirements are necessary. The main aim of engineer's background now is innovative thinking cultivation and creative work ability formation instead of traditional skill development which is not enough for successful engineering activities. An engineer of 21st Century must be a creative personality, who can reveal and propound himself a creative problem in all situations and surely solve this problem.

New ways of engineering education all over the world depends on the development of the human society in a whole and on the development of science, technics, technology and culture in particularly. Contemporary intensive processes of new pedagogical technologies formation and development can be considered as a part of new informational technologies speedy elaboration. High level of Russian engineers qualification is supported by innovative pedagogical technologies and by special programs of the engineering education.

Russia was famous earlier and is famous now for its theoretical developments in different branches of science.

Manuscript received on November 30, 2002

Engineering education is not an exclusion. You know well the name of P.K. Engelmeier who was not only engineer but one of the philosophy of technics founders [1]. It is necessary to mention the name of G. Altschuler [2] and M. Zinovkina [3] who search and contrive creative methods for children and adults, for students in particular. Now Russia need to use all its theoretical experience and try to implement it in the tutorial process.

Departments of the engineering education are organized now in several Russian technical universities. They are charged not only to use but to search, to find and to implement new pedagogical ideas in the background of engineers. Their activities can be carried out within the framework of fundamental disciplines complex i.e. disciplines of natural science, humanitarian disciplines and technical disciplines. The Department of the Engineering Education of the State Technical University MADI correlates its tutorial programs with programs of the general education departments such as departments of Physics, Mathematics, Chemistry.

The best way to get students to understand the importance of basic sciences learning is a real example. The most demonstrative example of basic sciences and technics integration is PC production process and its history. The first step was done in the 19th Century by M. Faraday and H. Becquerel who began to study properties of semiconductors. Then in 20-40 years of the 20th Century the fundamental theoretical items were proposed together with some prognoses of future practical semiconductor application. In 1923 Schottky was published the theory of solid state amplifier. In this theory the necessity of quantum-mechanical methods was highlighted. In 1940 during the Second World war the first crystal detectors for waves of centimeters in length was built. In 1947 Shockly, Bruttein and Bardin proposed and done the first semiconductor bipolar transistor. This year became a new era birthyear.

It is well known that more that 90% of electronic devices and systems are made using silicon as a basic material. On the Earth silicon can exist only as silicon dioxide or silica and as a part of different compounds. The transformation of the raw material into pure silicon single crystal can be considered as the purification from the case when silicon content is equal to 98-99 % (raw material) to the case when siliocn content is equal to 99.9999999 % (silicon single crystal or wafer). This kind of the transformation is possible only by using fundamental scientific knowledge and Hi-Tech tecnologies.

The way of silicon raw material into electronic devices demand knowledge and skills of different sciences and engineering:

raw material search and mining – Geology, Chemistry, Physics, engineering; silicon dioxide rectification – Physics, Chemistry, Material Science, Metallurgy, engineering; matrix and then devices production – again and again Physics, Chemistry, Material Science and engineering. The last step of some electronic devices, i.e. PC, demands to use mathematics and information science. During all steps of semiconductor devices production it is necessary to keep in mind the ecological problems which can follow these manufactures. Before manufacturing of devices and during this process it necessary to follow the market demands. Now it is well known that the every dollar invested in silicon wafer production will return multiplied by 18-20 after matrix manufacturing and multiplied by 100 at least when electronic system was produced.

It is necessary to note that sequences of engineering activities can play double-natured role: from one side we have some material objects i.e. machines, new materials, buildings, bridges, roads, etc. and from other side we notice a change in a human way of thinking and its social behavior. So, we can underline that social sequences of engineering activities to increase the engineer responsibility.

From our point of view the base of engineering creative work consist of high fundamental education, comprehensive imagination and patriotism. The latter can be strengthen if a student knows the ways of engineering development in Russia, if he knows the biographies of the great Russian engineers and scientists. One of the practical task for students is writing of reports on great people biographies. In its practical work the professors of the Department of Engineering Education use to visit Moscow Museums devoted to the great Russian Scientists and Engineers as well as Museums of Art and History. State Technical University MADI has its own museum where students can acquaint themselves with MADI formation and development and with biography of its graduates.

Fundamental education appears to be a result of mutual efforts of departments of general education such as Departments of Physics, of Chemistry, of Mathematics and by Departments of humanitarian sciences. Scientific cognition's methods used by different branches of natural science enrich a future engineer, give him an opportunity to make himself master of successful application of these methods. Learning humanitarian disciplines a future student receive a possibility to reach figurative selfrealization. One of the founder of quantum mechanics E.Heisenberg wrote that his breakthrough in Physics were based on his speculation arose during Platon's "Dialogues" reading.

One of courses developed by professors of the Department of the Engineering Education of the State Technical University MADI is the course "Engineering Creativeness Base". This discipline includes several world outlook sections but in a whole this discipline is directed to practical training. A future engineer must understand that the Universe can be cognized. Every engineer's project must be realized according the Nature laws which are under research infinitely. That is why the engineering education must not stay but it are developing too.

There are several stages of engineering activity that we can select. They are:

- problem searching and propounding
- invention creating
- project designing
- engineering research fulfilling
- project developing
- technology and industrial engineering
- an exploitation and evaluation of mechanisms and means of production
- a liquidation of dated or disused construction and machines.

An engineer of the 21st Century must also know the rules of marketing, advertisement and he can evaluate his commitment (including evaluation of production cost) and future profit.

An engineer of the 21st Century can work in an individual manner and as a member or a leader of a team. So, he must know how to organize his own work when he is alone and when his work is a part of cooperative work. That means that he must know some Psychology information.

All of these stages can be successfully carried out on the base of knowledge received during learning the course "Engineering Creativeness Base". Students of the second year learn it during two semesters. This discipline includes:

- a natural-science Universe pattern and a historical view on science formation and development from ancient civilization till nowadays;
- a historical view on technics creation and development;
- dynamics of science and technics interaction, a historical view on technical science formation and technical education origination;
- a consideration and using interdiscipline synthesis for development of a creative work skill
- an integration of knowledge in the area of natural science and using of natural science methods and techniques in an engineering activities
- characteristics of engineering activities and a structure of an engineering project;
- methods of different technical problems propounding and methods of scientific and technical creative work;
- ways of modern information technologies using in everyday engineering activities;
- an initial information from Psychology and using its imagination in an engineer activities;
- an engineer's responsibility, interaction of engineering activities and ecology problems;
- specific features of engineering thinking and innovation thinking cultivation;
- an element's, function's and structure's analysis as a part of a system analysis;
- an initial information about value analysis and value engineering;
- an initial information about marketing and advertisement;
- presentations of successful scientific and technical careers

By learning the course "Engineering Creativeness Base" students will adopted the ways of fundamental sciences using in their future creative work, will understand their own creative potential, will study the principles of a creative work in a team. A student obtains an opportunity to become a creative personality who possesses knowledge in rather wide frame from different sciences. After learning the course "Engineering Creativeness Base" students can generate new creative idea, or even create new technical objects.

During Centuries science and technics were as twins: i.e. Archimedes was one of the first engineer-scientist or vice versa scientist-engineer. The same words we can say about Leonardo da Vinchi, Galileo, Huygens, Gilbert or others. It is well known that every great scientist or engineer is a creative personality. This conclusion push us again to great importance of a creative work in engineering activities too.

The main goal of creative engineering activities is "a technical object". Every time the preliminary idea of any technical object promises a perfect product. During speculations and then during producing of this new item there are two types of work (this division is rather rough, of course): creative work which sometimes is very close to irrational thinking, and routine work the other name of which can be "rational thinking". More irrational in your work means the fact that you are closer to creative thinking and work. Father you from irrational thinking means the fact that you fulfilled now only rational work and your thinking now is rational thinking (Fig.1). You can see that "technical object" contains basic sides of a human activity – material, scientific, artistic – which can not birth and exist without creative work. It should be noted that every new creative idea based on the previous knowledge. You can follow the changing of any technical object i.e. ships, and you can

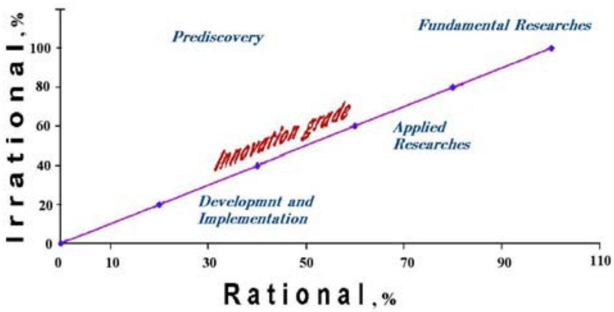

Fig. 1. The relationship of irrational and rational thinking and an innovative grade dependence for different types of engineering activitis.

see that every following exemplar has some feature of a previous one (Fig.2). This figure shows us one of a rule of an application for patent creation: every following step consists of the previous one.

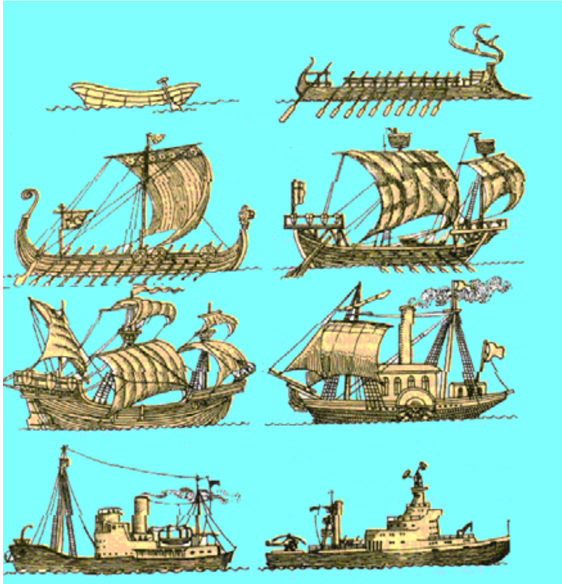

Fig.2 An example of more and more sophisticated models of ships as a result of a human creative work.

Looking at these ships we can follow the process of well-known idea transformation: oars plus clothing – quicker sailing… vapor plus clothing – quicker and more margin of safe… nuclear energy instead of electricity – more power, more time for sailing, more interval for velocity etc.

At present a man lives in the artificial environment. The logic of this environment development and evaluation depends only on intellect, knowledge and high moral principles of the human society.

To receive new perfect technical decision or to create new technical product is possible only if you know some methods. In application to engineering activities such method or methods are the methods of a creative work.

As a rule every stage of engineering activities consist of three creative acts. They are:

1. "a guessing act" (an idea) which results in clear propose or intention;
2. "a knowledge act" (a plan) which results in clear scheme;
3. "a skill act" (an implementation) which results in final technical project creation or pilot construction formation.

So, at first it is necessary to understand what methods can be considered as methods of a creative work. The second step is learning of this methods through using them as an individual person, then as a member of a team , and it is necessary to try to reach the leader place in a team. During learning of methods of a creative work all modern technical devices and tools must be used. For example, database of physical, chemical effects, database of some constructional elements, database of known technologies etc.

The method of learning can be transformed by using interactive self-instruction technology. From our point of view this technology is generalized one. Then cognitive, instructional and training activities are the main and leading activities for a student. A professor will play role of a consultant. One way of dialogues between a student and a professor is a formation of interactive web-site (www.ipmadi.narod.ru). The Department of the Engineering Education of the State Technical University MADI has its own interactive web-site, where an information which is necessary for students is situated and where its professors can find students questions and demands. So, professors and students can better get to know each other.

It is necessary to note that the most active students after learning several courses of the Department of the Engineering Education use their new knowledge in practice. For example, during methods of a creative work learning namely "brain storm" or "value analysis" ("Engineering Creativeness Base") several students used rules of work in a team ("Psychology of Business Interaction"). The best student value analysis carried out when they received as a task "automobile system of gas waste getting off" bellowed to that students who learnt the both above mentioned disciplines. These student found necessary information about several systems, analyzed them, they found necessary constructional-technological documentation and made a creative analytical work to propose their own modernization steps to increase ecology safeness of this system. Naturally because of their small practical experience and knowledge these proposition are not real for implementation in the production But the main thing is that they begin their creative work, enjoy it and want to know more and do better.

It should note that every time when it was necessary to use some information from any fundamental discipline (i.e. room heater modernization require using of physical effects: Ohm's law, Joule-Lenz' law, Stefan-Boltzman law etc.) the best propose and the most literate propose came from students who had good knowledge in this concrete discipline. Contrarily after learning of "Engineering Creativeness Base" we can notice the motivation increasing to learn basic fundamental discipline and we can note some increase of marks level that students receive later (Fig.3).

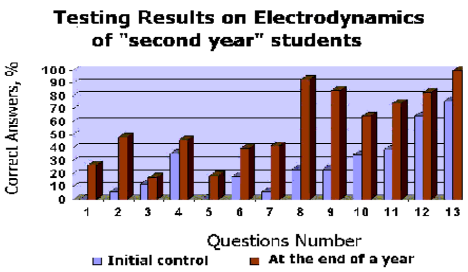

Fig. 3 The comparison of " the second year" students testing results on "Electrodynamics" fulfilled before and after "Engineering Creativeness Base" learning.

It is necessary to mention very interesting students projects carried out during learning methods of "brain storm" (increasing of walker safe in the street), of "focal objects" (it was several unexpected application of TV in the northern parts of the Earth) and "morphological analysis" (room heater modernization). Propounding of a technical problem was a task for students when the leakage of oil in 70th years of 20 Century was done as an example of global difficulty. Some students proposed their original decisions.

The analysis of correct answers shows that we receive approximately the expected Gaussian distribution. The initial questions (1-5) represents new material that students learned just before testing (brown raws). n the middle of diagram there are that questions which our students studied in school and then repeated them during their student life (blue raws)y see that after "Engineering Creativeness Base" learning the pattern of correct answers distribution is approximately the same one but correct answers percent increase (Fig.4)

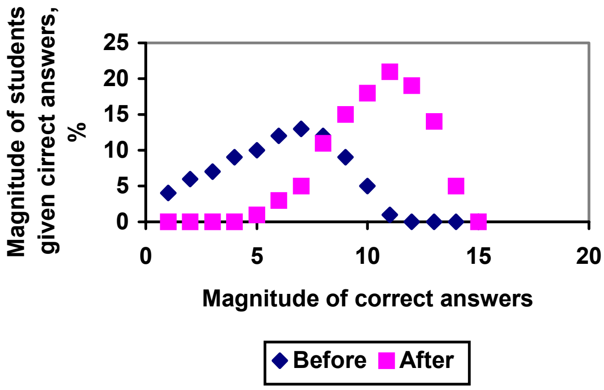

Fig. 4. The comparison of correct answers patterns before and after "Engineering Creativeness Base" learning for "the second year" students.

Practical tasks for students, their questions and demands, testing results allow the o professors of the Department of the Engineering Education correlates tutorial programs to teach talented and creative engineers.

It should be note that humanities in engineering education, the role of natural sciences in engineering education appear to attract a dramatic attention of the professors worked in engineering education all over the world. It is enough to read the papers presented on the 31st International Symposium "Engineer of the 21st Century"[ ]. The most of papers highlight the importance of basic sciences as well as humanities and creative work for teaching the real engineers of the Future.

DESIGNING IN MIND: CREATIVITY

Secil Satir[1], Elmira Sener[2]

Abstract — *Creativity as an hypothetical aptness, can be found in each and every person. This inclination exposes a creative idea as a result of a multi dimensional thinking system, and the idea motivates the designer in order to be materialized.*

The properties of creative thinking, the understanding of "four p" principles; "product", "process", "personality" and "press" in creativity, are the important creativity concepts that takes place in the continuity of this announcement.

Mentioning the experiments of creativity process in computer environment and their results, points out the differences between the creativity process in mind and in artificial mind. The presence of multi dimensional psychological factors effect the synthesis of thoughts in many aspects, whereas the images obtained from computers are insensitive and are varied in one dimension.

Therefore the fact that designing in mind is special to human and apart of human personality can not to denied.

Index Terms — *Creativity, human mind, creativity process, creativity process in computer .*

INTRODUCTION

Creativity is an impulse believed to be in every individual, an inner reaction that motivates the individual to think, act or to produce differently from the known.

Derived from the latin verb "creare", in german "kreativiat", the word creativity, is a perfection that brings out an independent idea, an action or a product as a result. However, this talent that can be improved with exact and hard working can be defined as talent for designing. Because to design means to form in mind, to organize and to sketch. It can also be explained as to prepare in mind, to perform, to organize ideas, to fantasize in mind etc. The meaning of the word "human thought" is a process of a multi dimensional thinking and materializing, giving a meaning to life.

CREATIVE THINKING

Creativity, just like design, includes a multi dimensional thinking process and the case of this process to be materialized. However, producing an original creative idea is not sufficient. It's required that this idea to be seen by the others. The materialisation of a creative idea can occur in an act; in the mimics, jests or words of a comedian; in a caricature, a picture, a statue or architecture; in a song, poem or an article; in a design object; in the solution of a daily problem; in a scientific discovery; in a plan or system analysis; in the process of overcoming an economical difficulty; in creating solutions for a business or engineering problem etc. Briefly it can occur in finding positive solutions for all kinds of difficulties.

As seen, creative thinking covers almost the whole life. And in environments that no difficulty exists, it is significant to individuals who know life and whose creativity improved in order to feed their motivation to search, find and present the beauties of life.

To improve creativity one may not need to know how it forms in ideas, yet the knowledge of how an idea forms in mind may arise desire to feed the memory. For this reason, the knowledge of how and where an idea forms in the brain, how information is stored and how the communication is established in brain cells.

According to the studies of F. Vester, in the physiologic structure of thinking the stimuli that come to the brain are transferred between the cells to be evaluated, and 500 billion synapses work to transfer the stimulus between the brain cells [1]. With the help of these synapses, one can think, learn and remember systematically. The stimuli, also known as the information models that turn into substance as protein balls between the 15 billion brain cells, are continuously in communication with themselves and the new coming stimuli. These information models are always in a cycle of changing from substance to energy and energy to substance. The more the memory is fed, the denser the communication network would be, as long as there is not an obstractive reason.

These researches in creativity, lasting since 1950's, improve much with the studies of Guilford. Correl and Preiser define creative thinking extensively with the properties stated below [2] [3] ;

Properties of creative thinking:

* fluency
* flexibility
* originality
* problem sensitivity
* re-structurability
* materialization
* activation with every detail

These properties show different concentration in every individual's idea. For some people fluency of the idea is in the first place, while for some others the most important property shifts to flexible thinking or to problem sensitivity.

Dimensions of Creativity

According to American creativity researches, the "four p" principles defines the dimensions of creativity [3].

The "four p"'s are;

1 - “product”
2 - “process”
3 - “person”
4 - “press”

Product

It is the materialization of an original idea formed by creative thinking into something that can be seen, touched, heard etc. Creative product leads to an exciting conclusion in scientific and art studies. It may also put forward solutions to the daily problems of private and business life. Above all, creative product is original and unique. Creative product is something that a person is not accustomed to; something surprising, logical, useful, exciting; an existing product that is changed, altered or entirely transformed; it brings out feelings such as joy, enthusiasm and relief.

Process

The formation of creativity in brain is not a mysterious process as many people believe, but a solution of a tiring work, effort and struggle.

Linneweh classified thinking into two groups as "visual thinking" and "intellectual thinking". It is seen that visual thinking can be continously used in every situation. The transformation, alteration and re-organisation of the problem elements are in the coverage of visual thinking. It is an idea that has a strong perception capability. For that reason the formation of new connections and the increase of sensibility in visual thinking, develop creative talent and imagination, in other words the inner eye. It is an important fact for invention. On the other hand, intellectual thinking is based on logic, succeeding in understanding, comprehension, perception, presentation of what is learned and making use of them. Visual and intellectual thinking must not be separated, keeping in mind that creativity can be found in each and every person and it may build on an intermediate intelligence base. However, it is considered that intellectual thinking develops in intelligent people while visual thinking develops in creative people.

The stages of creativity process starts with the perception and analysis of problems by the inner reaction of the individual. It is followed by gathering information. The information stored in individual’s memory, try or force to find ways of communication with the intervention of the synapses and they either enter an incubation phase or go in hypothesis formation.

As a result of these stages that can be named “black box” and “transparent box”, creative idea comes out as “a sudden thought flare” or “an idea synthesis”. For creativity process to be completed, the born idea should be examined, scrutinized, readied to be materialized and finally materialized.

The problem that needs solution should be constructed first, in order to materialize the creativity process. No matter the sort of existing problem, the construction should be simplified. The simplification means the purifying of the problem from all complexities. The problem may be easier to understand by classifying, may be defined as one by separating from the others, or may be defined again by analyzing the roots keeping the saying “the solution of a problem lies down in its roots” in mind.

Person

It is known that creativity lies on at least an intermediate level of intelligence basis. For this reason creativity exposes the intellectual aspects of the individual. However, creativity is also concerned with the motivation field of the person, because the creative idea that forms in the subconscious and arises as a sudden thought, comes to life depending on the drives, in other words motivation.

Creative person overcomes complexities and conflicts, has self-confidence, resists obstacles and judges independently. He/she has characteristics such as curiosity and ability to provoke imagination. Creative person usually does not suppress his/her personal feelings and is determined on his/her way to the conclusion. He/she is sensitive to the unique and beautiful. Attaches importance to diversities. He/she is suspicious and notices the negative and absent parts of the existent with this suspicion. He/she is interested in mental studies. Differentiates ideas and objects. May have extreme excitement reactions. Knows himself/herself well.

Press

Press may either create or exterminate creativity. Creativity can not exist without a physical or social environment. Above all, attractive, exciting and independent press motivates creative thinking. On the other hand, lack of confidence, constrained behavior and senses, intolerance and various social and cultural obstacles barricade the creativity.

CREATIVITY PROCESSES IN COMPUTERS AND THEIR COMPARISON

In the century we live in, human brain is being studied in many aspects and its structural properties are being modeled in means of artificial intelligence. This improvement exposes the development of electronic machines that can compete with human intelligence. Despite the fact that the user spends less effort, it seems that machines with artificial intelligence will become more capable as their technology develops.

As known, designing in computer environment, presents efficient improvements in finding practical solutions, creating virtual reality, visualizing the design, designing interfaces and creating artificial intelligence. This field, where the recent technologies are utilized, reaching a synthesis with words and numbers in theoretical dimension and with geometric shapes in visual dimension, may help the creativity studies. New patterns may be exposed by putting forward multiple possibilities from the geometric patterns which are recommended by the computer programmers and appreciated by the users.

"Harold Cohen designed a computer program which can generate drawings without the requirement of human interaction and produce an infinite number of variations within certain rules" [4]. However, such programs are limited with the thinking style of the individuals designing the computer program and they can not include all the users.

While it was easier to draw the planar and sharp contoured geometric structures in the beginning, with the developing technologies, designing with organic lines (alias wave front) and using the advantage of flexibility offers a wide range of design possibilities to the user. The designer uses this infinite opportunities as a tool for his creativity. Utilization of the visual abilities of the designer is important in developing computer programs, providing alternative production methods and presenting an easier use.

The programming which was "process oriented" before, has now turned into "object oriented" programming in realization of synthesis related to end user requests and analysis [4].

The Importance and the Difference of Designing in Mind

Searching alternative forms in design is useful with the use of computers in order to gain time and to produce multiple alternatives. Computer programs may present the form study in ways of step by step mutations. For example, designs of furniture back supports drawn in computer environment or alternative designs of some abstract forms improved by means of mutation, can vary only in their own limits in means of geometric forms. But in this variation, how can sensitive ideas, that effect the design and feed the human senses by taking place in permanent memory, be projected to the program itself ?

In contents of object oriented programs; tool, machine, objects, jewelry, environment, building etc. in all fields of design, except the assisting role of computers in speeding up the process, the first and sudden creative idea of the place or object design is particular to the individual. With the use of advanced computer technologies, exposing the idea using a touch pad and realization of creativity process by transferring organic forms to an electronic interface, is useful in presenting the idea as fast as possible.

On the other hand, the effect of the cultural structure which does not exist in computer programs, the psychological status of the individual and images on creative senses can not be denied. The most important property of creative intelligence, also defined as emotional intelligence, and its main difference from designing in mind, is the reflection of this emotionality on creative thinking.

CONCLUSION

The age we live in is the information age. Science and technology aim a better, healthier, longer and happier life for us. A happier life is equivalent to the usage of a wider range of creativity. If the designer can design a product that suits his sensibility, using the available programs directly or with the use a few key strokes and still continues to enjoy drawing with his hand, then science and technology would succeed in their task.

While the new disciplines introduced by computers such as "virtual reality", "interface or interaction design", "design for visualization" and "artificial intelligence" replace the design disciplines, they also should remain within certain limits leaving the design process to the designers themselves.

If the computers aim to replace the human brain, then the individuals would have to record all their daily incidents, perceptions, senses both in verbal and figurative and schematic ways to their computers. Regarding the informations and perceptions that the human brain finds necessary to forget, solving the problem would be more complex.

Computer technologies can make the work easier, exalting the creative personalities, instead of depriving the person of his joy to design and create.

Given all these information and ideas, creativity can be defined as a source of happiness that gives meaning to life and confidence to deal with the obstacles in every stage of our lives.

INTEGRATING LIBERAL EDUCATION INTO ENGINEERING TECHNOLOGY SENIOR DESIGN COURSE AT MIAMI UNIVERSITY

Suguna Bommaraju[1], Ron Earley[1] Dave Hergert [1]

Abstract *—At Miami University, the senior design course in the baccalaureate Electromechanical Engineering Technology (EMET) Concentration takes the form of a yearlong liberal education capstone course. In addition to conducting engineering analysis, students are encouraged to integrate ethics, environmental issues, cost/benefit analysis, safety, and aesthetics into their project. Miami emphasizes critical thinking, sharing of ideas, synthesis, and informed reflection as significant precursors to action while focusing on student initiative to define and investigate the problems or projects.*

The inclusion of the liberal education component has proven to be an exciting challenge to the students. Alongside the project design work, the students have to reflect on personal and societal benefits while considering the reality of costing of the projects and the impact in terms of safety, environmental, or ethical issues related to producing the item. The integration of liberal education into the curriculum has generated an implicit understanding of the role of humanities and social science courses in enhancing engineering education.

Index Terms — *Miami University, Liberal Education, Senior Design Course*

INTRODUCTION

In 1996, the department of Engineering Technology at Miami University, OH, developed a capstone course 'Senior Design Project' in its Electromechanical Engineering Technology degree program. This capstone course is required in the final year for all students graduating with electrical/computer concentration or mechanical concentration[1]. The primary objective of this course is to make the students work in teams to conduct major open-ended research and design projects. This allows the students to be striong team player, utilize their knowledge and skills acquired in earlier course work, and incorporate engineering standards and real world constraints such as economical and social factors, marketability, ergonomics, safety, aesthetics and ethics.

To date, the senior design course has been successful as a Capstone course, meeting the requirements of Liberal Education component. After a brief backgtound on Liberal Education at Miami, the paper outlines the senior design course. The philosophy of embedding the liberal education component in the course is presented later. Finally, the paper shows the assessment techniques employed for continuous improvement of the course.

LIBERAL EDUCATION

Unambiguously a well-rounded education of engineering graduates must include a considerable liberal education component[2]-[9]. Although an engineer's job is to make things better, more efficient, and cheaper, other non-engineering skills such as writing, speaking and effective communication, as well as social and societal awareness, environmental consciousness are involved. It is important that engineering curriculum is comprised of considerations of the appropriateness of various technical solutions and resolution of conflicts that extend beyond classical engineering optimization. Such conflicts involve humanistic considerations that a technical solution must address conscientiously with careful thought.

Albeit the idea to plant the seeds of a social conscience in every graduate is an old one, its implementation at universities is complex and is subject several constraints. In order to estimate the current thinking among academia, a question was posted on the ENT Listserv with regard to if and how liberal education is incorporated in enginnering technology curriculum. The data collecetd from that inquiry indicated a strong support for including Liberal Education component. It appears that most of the engineering students are engaged in takling communication, history,math and science courses in their freshmen to senior level. Some of the postings on the listserv suggest that liberal education concepts should be introduced early on at grade school level (K-12).

The reluctance to add liberal education courses to engineering curriculam stems from the concern that there may be little room left for engineering courses. There is no doubt that introducing liberal education component by including liberal arts in an engineering can be only minimal at best to maximize the time to teach engineering subjects.

One of the ways to overcome this limitation is to embed liberal arts components in one or many senior design courses, in particular, any Capstone engineering design or project course.

THE MIAMI PLAN

At Miami University, all students must complete courses identified as parts of the Miami Plan as well as courses in Major[1],[8]. The Miami Plan for liberal education is an ambitious and complex plan. Based on some of the best thinking at the time of its development, the plan emphasizes four foundation principles. In addition, the plan aims to provide breadth through foundation courses, engagement through seminars, depth through the thematic sequence, integration through the capstone experience, and options for all disciplines to create courses based on the principles of the plan[4]. These are not novel ideas in liberal education program design. What makes the Miami plan unique, and also complex, is that it includes all of these ideas, emphasizing forms of inquiry and pedagogy, allowing overlap among requirements, and operating in an unresolved alliance with college and major requirements.

The Miami plan has two parts; Foundation and Focus. The 'Foundation' requirement is met by taking 36 semester hours of courses (Table-I). The 'Focus' requirement, is met by taking a minimum of 9 hours in a Thematic Sequence outside the major and a minimum of 3 hours in a senior Capstone Experience taken in the final year of study (Table-I).

Typically, a student registered at Miami University would fulfill 28% Foundation requirement, 9% Focus requirement and 63% in the field requirement as shown in the Pie chart.

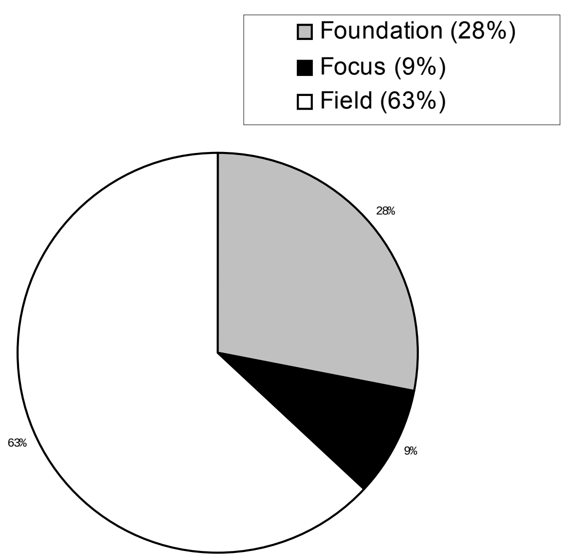

FIGURE. 1
DISTRIBUTION OF COURSE WORK

The Capstone presents an excellent opportunity to bring together the student's entire undergraduate program. The Capstone Experience, usually completed near the end of baccalaureate studies, integrates liberal learning with specialized knowledge. Each Capstone emphasizes sharing of ideas, synthesis, and critical, informed reflection as significant precursors to action, and each includes student initiative in defining and investigating problems or projects.

Capstones may be completed in or outside the major; in some departments, the Capstone Experience will be a requirement of the major. For students not majoring in the department where a Capstone is offered, prerequisites often may be met by completing a related thematic sequence. All Capstones presume a significant scholarly background of specialized study in a major as well as in liberal education course work.

At Miami University, the senior design project assimilates engineering design, analysis, and liberal education concepts such as cost/benefit analysis, environmental issues, and ethics. The Department of Engineering Technology developed the Senior Design Course in 1996. The Liberal Education Council later approved this sequence as a Capstone course. The department has seen the liberal education component in ENT 497/498 as a valuable asset. By focusing on the principles of liberal education at Miami, students learn to ask why they are designing a project, not just how to design it.[1],[9],[10].

TABLE-I
FOUNDATION AND FOCUS SEMESTER HOURS

Foundation Courses (36 Sem. Hrs.)		
English	Fine Arts	Humanities
Social Sciences	US cultures	World Cultures
Biological Sciences	Physical Sciences	Mathematics/Technology/ Reasoning
Focus (9+3 = 12 Seem. Hrs.)		
THEMATIC SEQUENCE: 9 hours Typically a Three Course Sequence outside the department of major		CAPSTONE EXPERIENCE: Integrates Liberal Learning with specialized knowledge

BASIC ELEMENTS OF SENIOR DESIGN COURSE

The senior design course is divided into two semesters: ENT 497 and ENT 498. The course addresses the application of the knowledge of senior Engineering Technology students to perform a major open-ended design project. This allows students to work in design teams that utilize their combined expertise and skills to achieve a successful design. Each group of students has a faculty mentor.

The fundamental elements of the design process are considered in this course through continuous interaction with faculty and bi-weekly seminars by outside professionals. In this course, a variety of methods is offered to the students to enable them to develop their designs. As appropriate, seminars on topics relevant to the projects and design are conducted by the faculty, students, and guest speakers from industry and other institutions. These topics include Miami Plan, Ethics, Cost Analysis, Liberal Education Component, U.S. Patents, Engineering Design Project, and Design Alternatives.

Along with Guest speaker's seminars, the students and the faculty meet regularly. In each of these meetings, students generate minutes that describe the discussions, activities to be conducted in the future, progress to date, and persons responsible for future tasks.

The design projects include the establishment of objectives and criteria, synthesis, analysis, and evaluation. In all designs, students will consider realistic constraints, such as economic factors, marketability, human factors, safety, reliability, aesthetics, ethics, and social impacts.

The projects offered in this course are chosen from real-world problems. This is intended to enable students to recognize current needs and trends in industry and society. The first part of the project (ENT 497) deals with feasibility studies or proposals. The second part (ENT 498) is the actual implementation, testing, and production or simulation of the prototype. Because design is an iterative process, the students may find it necessary to adjust their proposals from that in ENT 497.

At the end of the second part (ENT 498), the students are required to give a demonstration of their developed design. This is done by using computer simulation or by physical testing. The format for the final report is similar to that of ENT 497 but contains more information about the final design: analysis, mathematical model, cost, and operational procedures.

In general, students are graded (Table-II) and evaluated according to their performance in four areas: 1) finishing the proposed design, 2) reports, which include final report, minutes, and other progress reports; 3) participation, which includes meeting attendance, discussions, active involvement, and leadership in carrying on one's responsibility; and 4) midterm and final presentations.

It should be noted that the students are working in groups to emphasize the importance of teamwork in real life situations. Each group is responsible for dividing the different tasks among its members, writing reports, and presentations. Individuals within a group may receive different grades. Grades are determined by regular evaluations taken during the semester by the instructor and by the students for each individual. While the student input will be given considerable consideration, in the event of conflicting opinions or other such problems, the ultimate grade determination will be by the instructor.

Students submit written assignments in ENT 497/498.

- Mid-Term Report
- Final Report
- Weekly Journal Entries
- Reflective Essay (Appendix-A)
- Presentations

TABLE-II
ENT 497 COURSE GRADE SHEET

Date: ______________

Maximum Points Possible	Graded Item		Points Earned
(15 points)	Project Proposal		
(45 Points)	Final report		
	(2 points)	Title	
	(2 points)	Statement of Purpose	
	(10 points)	Scope & Methodology	
	(10 points)	Expected Findings	
	(10 points)	Conclusions & Rec.	
	(2 points)	References	
	(7 points)	Appendices	
(15 points)	Quality of Participation		
(30 points)	Presentation		
(15 points)	Use of Engineering Analysis		
(30 points)	Weekly Journal & Reflective Essay		
		150 points Total	

The following assessment tools are used in the course.

- Presentation Evaluation (a panel of judges evaluate student projects and presentation at the end of each semester) (Appendix-B)
- Liberal Education Survey (Appendix-C)
- Student Evaluation (divisional student evaluation done at the end of the course)
- Two Minute Survey (usually done after each guest speaker)

EMBEDDING LIBERAL EDUCATION CONCEPTS

All engineering colleges require engineering design from their Senior Design students. In order to foster the consideration of social context and other non-technical issues when designing, building, and implanting engineering projects, liberal education concepts are introduced into the senior design course. These are 'critical thinking', 'understanding contexts', 'engaging with other learners' and 'reflecting and acting'.[1]

- Critical thinking: Critical thinking is to involve imagination, intuition, reasoning, and evaluation in such a way to analyze systematically and solve complex problems. [1]
- Understanding Contexts: The relevance of the problem and the solutions to the society, environment, and the well being of people is as important as the problem and the proposed solution.

Knowledge of the conceptual framework and character of the society are essential inputs. [1]

- Engaging with Others: Only through open and honest exchange of ideas with piers and teachers and colleagues does one accomplish a balanced solution. Active listening, exchange of ideas, reevaluation of established views and critique through actively seeking other's opinions are corner stones to achieve a proper result. [1]
- Reflecting And Acting: Practice decision-making and evaluation of the repercussions thoughtfully. The idea is to enhance personal moral commitment, enrich ethical understanding, and strengthen civic participation. [1]

Students in ENT 497 are required to first establish who is in their group, and then choose a project. Often students have more than one alternative, so they can choose a project that best fits their ability and interest. Groups are altered if there is little diversity in terms of background.

Next is the planning stage, where students discuss the design, establish objectives, prepare a Gantt chart, and assign tasks. Literature research and preliminary reports make up the rest of the semester. All areas of critical thinking (analyzing, formulating alternatives, implementation, and documentation) are done in this class. The mid-term report gives the instructor a clear understanding of the progress of the group.

Following is an analysis of how the department meets the four principles of liberal education at Miami.

Critical Thinking In Liberal Education

All senior design projects require a component of engineering analysis. Critical thinking in engineering technology is most often is centered on analysis and design. The principles learned in prior courses are used as a guide for conceptualizing a complex project, designing the system using engineering analysis to mathematically model the system, then building it. Critical thinking skills are used in analyzing problems, formulating alternative solutions, implementing solutions, and documenting the results. [10]

Here are a few examples:

- A group of students designed a fiber optic multiplexer that allowed a computer to be connected to a matrix of cables. The project was complex and yet quite successful. The company that sponsored this project later patented the final system. To design the mechanical part of the system, students used principles of Statics, Strength of Materials, and Machine Design learned in their engineering technology courses. The accuracy and repeatability of the alignment was crucial to communication being established. Students spent most of the year determining the type of electrical control to be used (i.e. open or closed loop) and designing the mechanical apparatus. They also evaluated a wide variety of designs to best move the platform for proper alignment of the cables. The final decision was that the control system had to be closed loop because of the precision involved. The students designed the control system using differential equations and other modeling techniques taught in their control course.
- A group of students designed a PCB electrical board etching system that allowed schematics to be drawn on a computer, and then downloaded to a robotic arm that etched the board. All aspects of the system (including the robot) were designed and built by students. The students used the knowledge they gained from their mechanical courses, digital design, and programming courses to build this system. The software was written in Visual C++; I/O ports were used to control the machine. The machine entirely built by the students required a tolerance better than a thousandth of an inch. This would normally take months to design and build. Owing to the time spent in planning and preliminary design, the team was able to successfully build, program, and test this complex machine in one weekend.

Engaging With Other Learners

All groups have two or three students in them. Students are required to meet at least once a week outside of class, and keep the minutes in a journal. The instructor regularly reviews the journal to see how well the students are working together. If there is a communication problem, the instructor resolves it quickly, rather than let it fester throughout the course. [10]

An example of engaging with other learners follows:

- For two different years, a group of ENT 497/498 students served as advisors for the F.I.R.S.T. Robotics competition. This national competition has students design a robot in a 6-week period to perform a task. Over 800 colleges and high schools participate in the national event. Our group advised Northwest High School students on all aspects of the robot design. They were also involved in raising funds for the national competition in Florida. In 2000-2001, Miami/Northwest placed first in the region and runner up nationally. In 2001-2002 our students placed first in the region and third nationally. This project had a combination of high school students, college students, and engineers from industry working together to produce the final design. The ability to work so well together in a short time frame is tribute to the communication skills of Miami students.

Not all students communicate well though. Sometimes one student will control the project while others watch. This becomes obvious from the journal entries, and students are informed that group responsibilities must change. All students should contribute equally, depending on their interest and talents. Limiting the maximum number of students to three has also helped with this problem.

Understanding Contexts

Understanding Contexts includes adding a conceptual framework, cost/benefit, and cultural implication to a student's knowledge base. [10]

Rather than rush to build the project, students planning are the focus in the early part of ENT 497. Later, literature research and brainstorming sessions help the student to consider all aspects of the project. Feasibility studies help students envision the effect their product will have once it is designed and produced.

The central focus of the projects is engineering design; so all projects are required to have a significant component of engineering analysis. Students generally find an industry sponsor to fund and mentor the project. This way, students gain a perspective outside the classroom.

Understanding contexts includes other factors besides mathematical analysis. Students are required to include in their design such topics as cost/benefit analysis, safety, ethics, environmental issues, and aesthetics. The company sponsoring the project also mandates these components. Students see the context that the project will be used in, not just engineering analysis.

During ENT 497, guest speakers visit often. Attendance is mandatory on these evenings. A list of subjects presented by guest speakers for Fall 2002 is:

- Miami Plan – August 29
- Ethics – September 12
- Cost Analysis – September 26
- Liberal Education Component – October 10
- U.S. Patents – October 24
- Engineering Design Project – November 7
- Design Alternatives – November 21

Speaker topics are partly determined from student and industrial feedback in previous years. These topics help students step back and look at the project as a whole, rather than designing for the sake of design. A couple of examples of understanding contexts are given below:

- A group of students had a preliminary design for a robotic system that sprayed a fiberglass coating evenly on a tank. They took into account cost/benefit analysis, but not safety. After the instructor required them to look at all aspects of the design, they discovered that the project, if built, would not meet OSHA standards. They redesigned it, and the company is now using the robotic system.
- A group of students designed on paper a brake caliper for an automotive manufacturing plant. They did six different designs. They determined that some of the designs, even though more cost effective, could lead to carpal tunnel syndrome in the company employees. They chose not to go with this type of design when building the final project.

Reflecting And Acting

Reflecting and Acting is demonstrated by requiring students to think what they are designing before building it. The Reflective Essay is due at the end of each semester. It encourages students to evaluate their Senior Design experience with regard to the four goals of liberal education. The report guidelines are in Appendix A. Shown below are student comments from selected Reflective Essays. [10]

- "The goals of the Miami Plan for Liberal Education, in particular the goals of critical thinking and reflecting and acting have been instrumental in the preparation of this project."
- "Communication was one of the most important aspects of this project…because we had clear and concise communication, everyone felt they had a part in the final design."
- "In closing I would like to say that ENT 498 was the most difficult course to date. Not the project itself, but trying to complete the project in such a short amount of time. If I had to do it all over again, I would have insisted on a project that could be completed in a third of the time. By not speaking up, I allowed us to take on a project as complex and involved as this, and open ourselves for potential failure."
- "The communication that Tim and I had… was critical in the development of the project as a whole."

This essay has helped students observe their performance in the course. It helps them see how the breadth and depth of subjects they learned at Miami, including engineering technology, speech, English, philosophy, etc., helped shape their talents as they prepare to work in industry.

EVALUATION OF THE COURSE

At the end of ENT 497, students judge each other's projects and presentations (Appendix-B). While one group is giving the presentation, the remaining students observe and evaluate. The same evaluation form is given to outside judges in ENT 498. The outside judges consist of industrial representatives and faculty from other universities. For the past two years, some of the Miami faculty judge University of Cincinnati (UC) senior design projects and professors from UC evaluate ENT 498 presentations. Input from other colleges has helped us see areas for improvement in the sequence.

For example, in 2000-2001 the presentation day was somewhat disorganized because students wanted to change the time of their presentation at the last minute.

This confused the judges. Now, all students agree to a presentation time weeks in advance. This time schedule is strictly followed.

Students performing the presentation evaluation in ENT 497 tend to be quite honest in their critique. This helps students revise their presentation for ENT 498 the following semester.

The department also uses presentation evaluations to help evaluate the course. For example, the judges from ENT 498 last year made note that some groups had trouble with their speaking ability. They seemed unsure of themselves. To help correct this problem, the faculty is now requiring students to do more practice presentations before being must first create a timetable for completion. Creating objectives and judged. The presentation evaluations will be checked this year to see if the oral presentation is improving.

As stated earlier, the Reflective Essay and weekly journal entries help students observe their contribution to the course.

EVALUATION OF LIBERAL EDUCATION COMPONENTS

The assessment tools used in the course are an aid to the faculty and students. Student evaluations help ensure that ENT 497/498 is meeting the needs of the department and Liberal Education. The Liberal Education survey helps the faculty determine if students understand and appreciate this component of the course.

The Liberal Education Survey began in the 2000-2001 school year. Appendix-C contains the questions asked and a summary of the responses. As can be seen, students in general understand and appreciate the liberal education component of the course.

At the beginning of the school year, faculty meet to discuss ways of implementing improvements based on the survey results from the previous year. For example, Question 7 on the survey asks if the course has helped the student understand ethical issues related to engineering technology. In 2001-2000, the response was 2.97, but in 2001-2002, the response was 3.31. In the 2000, we showed a film on ethics relating to the Challenger disaster. This film generated much discussion in the class. Last year, we had only a short discussion on ethics. To improve on the 2.97 score from last year, we invited an engineer to discuss ethics both from both a moral and legal aspect. The survey will again be used to see if this helped the score.

As for the writing assignments, both years show that while students complain about the amount of written assignments, they do understand the value of journaling, reflecting, and reporting on their project.

CONCLUSION

All engineering colleges require engineering design from their Senior Design students. Most also require cost/benefit analysis, environmental issues, ethics, etc, although these topics are often seen as a minor component of the course. In the Engineering Technology department, these issues cannot be pushed to the background. By focusing on the four principles of liberal education at Miami, students learn to ask why they are designing a project, not just how to design it.

Some of the faculty in the department was initially skeptical of including liberal education in the course. Students take a number of engineering technology courses before enrolling in ENT 497/498, so why not focus on assimilating engineering design and analysis into their project? The thinking was that including liberal education provided little value to engineering analysis and design. Indeed, the quantity of liberal education in the required foundation courses was sometimes seen as a handicap, rather than strength.

Partly by co-teaching ENT 497/498 with other instructors, partly from seeing the effects of including liberal education on the final projects, and partly from listening to guest lecturers, most of the faculty have come to see the value of including all aspects of student learning in the course.

The department, while initially skeptical, has made a valiant attempt to integrate liberal education into the ENT 497/498 sequence. It has been a challenge for most of the faculty, because the engineering programs they were in included few, if any, liberal education courses. Their senior design experience focused purely on mathematical design and analysis.

In the beginning, at times the faculty felt unsure of what they were doing. Communicating with other departments that have a senior design course (such as Manufacturing Engineering) has helped the department develop the course. Having more guidance from the Liberal Education Council would have helped the ENT department understand what was expected. Input from LEC was especially necessary because the department has no other Miami Plan courses to use as a guideline. Overall, the department believes it has successfully integrated the Miami Plan for Liberal Education in the course, but is not sure if this is what the council is looking for.

Some of the faculty believe that ENT 497/498 is the strongest course in our department. The course is being reviewed for continuous improvement. The faculty is contemplating to utilize the course across varied disciplines to supply liberal education component in their curriculaum at senior level..

APPENDIX A

INDIVIDUAL REFLECTIVE ESSAY

Write a 2-3-page essay on your experience in the senior design project. In your essay, address the issues discussed below. Please remember that a reflective essay is more about self-assessment, performance, and lessons learned than just giving oneself a letter grade.

The objective of the individual reflective essay is to allow you to reflect on your experience in conducting your senior design projects. One way to define reflection is to self-assess one's performance in achieving a certain task. The question is how well did you perform in this course? How did you arrive at this conclusion? Another way to define reflection is to compare and contrast the course objectives to what actually happened. For example, the main objective of the course is to *utilize the application of the senior students' knowledge in science, mathematics, and engineering to perform a major open-ended design project.* The question now is: were you able to do that? Why or why not?

Another course objective is integrating liberal education goals (i.e. critical thinking, understanding contexts, and engaging with other learners) and professional engineering goals. These may be found in the principles of engineering science, manufacturing process and methods, and engineering design. See the text for more information. Again, how do you evaluate your experience with regard to this objective? In your opinion, did the course achieve the Miami Plan' requirement for a capstone experience? Why or why not?

Thus, one thing we would like you to do is to read the course syllabus, one more time, and reflect on your experience in the course. Other aspects of the course and the whole experience that you should to reflect on are:

A group of students had a preliminary design for a robotic system that sprayed a fiberglass coating

- Team work: you and your partners' ability to perform in a team.
- Communication: your ability to document your research, to present your results, and to communicate with your advisor, team members, and customer.
- Design: your ability to perform an open-ended design problem. How do you evaluate this experience versus other engineering courses? Explain.
- General skills and knowledge, such as AutoCAD, computers, theory, electronics, machining, etc. How do you evaluate your abilities to apply such skills in your project?
- Learning to learn on your own: how do evaluate this aspect of your performance in this course?
- Your performance, in general: how do you evaluate your own performance? What did you do well and what can be improved? What are the lessons you learned in this experience?

TABLE-III

ENT 497 Presentation Evaluation

Group Name _________________

Objective of Project Clearly Stated	Very Good	Good	Fair	Poor
This includes problem statement, customer, and given constraints.				
Synthesis of Group	Very Good	Good	Fair	Poor
This includes brainstorming ideas, using constraints to bring together different components, ideation, and creating schematics and graphical representation of ideas.				
Quality of Analysis:	Very Good	Good	Fair	Poor
Did the group demonstrate the use of engineering science, science, mathematics, statistics, and other modeling techniques to evaluate their solution?				
Testing and evaluation:	Very Good	Good	Fair	Poor
They discussed the approach they used to test and evaluate their hypothesis, model, or solution. Explained clearly the constraints used to achieve that.				
Literature Research	Very Good	Good	Fair	Poor
Includes library research as well as company literature, web surfing, etc.				
Progress of Project	Very Good	Good	Fair	Poor
They used schematics, Gantt chart, narrative, cost, and advantages and disadvantages each approach to the design.				
Future Work	Very Good	Good	Fair	Poor
They discussed their plans for the future, including after the year is over.				
Vocal Quality	Very Good	Good	Fair	Poor
This includes speaking to the audience, holding a level of interest, using connective sentences.				
Appearance of Group Members	Very Good	Good	Fair	Poor
Equal Time for Each Member of Team	Very Good	Good	Fair	Poor

Time of Presentation (minutes) ___________________________

APPENDIX C

TABLE-IV

ENT 497/498 Survey Results, 2000-2001 & 2001-2002

SA = Strongly Agree, A = Agree, N = Neutral, D = Disagree, and SD = Strongly Disagree.
Critical Thinking
1. I believe my critical thinking skills have been enhanced by this course. **SA A N D SD**
2. I believe that my critical thinking skills have been enhanced the work. I have done on my project. **SA A N D SD**
3. I believe this course stressed thinking and not memorizing. **SA A N D SD**
4. I believe this course provided many opportunities for critical thinking about problem solving, program design, and solutions **SA A N D SD**
5. I believe my critical thinking skills have been enhanced by the writing **SA A N D SD**
Understanding Contexts
6. I believe this course helped me understand the positive and negative consequences of the design process. **SA A N D SD**
7. I believe this course helped me understand some of the ethical issues related to engineering technology. **SA A N D SD**
8. I believe this course helped me understand the cost/benefit to a design project. **SA A N D SD**
9. I believe this course helped me understand the manner is which design engineers think and act. **SA A N D SD**
10. I believe this course helped me become sensitive to the consequences of implementing a design. **SA A N D SD**
Engaging With Other Learners
11. I believe the class activities have allowed me to engage with other learners in an effective way. **SA A N D SD**
12. I believe this course has improved my ability to work and solve problems with others. **SA A N D SD**
13. I understand the importance of group work for engineering technology professionals. **SA A N D SD**
14. I learned some things I did not know by working with others. **SA A N D SD**
15. Working with others has helped improve my communication and listening skills. **SA A N D SD**
Reflecting and Acting
16. I believe that the structure of the course has provided opportunities for me to reflect upon the concepts I have learned and apply them in an effective way. **SA A N D SD**
17. I believe that my design will help me reflect upon the concepts I have learned and apply them in an effective way. **SA A N D SD**
18. I believe this course helped me understand the need to reflect before implementing an engineering design. **SA A N D SD**
19. I believe this course helped me to take into account all aspects of an engineering design **SA A N D SD**
20. I believe this course helped me to reflect before acting in other area of my life **SA A N D SD**
Characteristic Ways of Knowing
21. I believe this course helped me to understand the importance of understanding a problem before trying to solve it. **SA A N D SD**
22. I believe this course helped me to understand the importance of designing a solution before trying to solve a problem. **SA A N D SD**
23. I believe this course helped me understand the importance of meeting a users needs when designing a project. **SA A N D SD**
24. I believe this course helped me understand the importance of safety in design practice. **SA A N D SD**
25. I believe this course helped me understand the importance of logic when solving a problem. **SA A N D SD**

The questions are summarized based on the following numerical assignments:

Opinion	Number
Strongly Agree	4
Agree	3
Neutral	2
Disagree	1
Strongly Disagree	0

The survey results for the past two years are shown below:

Question	2000-01 Average	2000-01 Standard Deviation	2001-02 Average	2001-02 Standard Deviation
1	3.47	0.52	3.38	0.62
2	3.33	0.72	3.50	0.63
3	3.80	0.41	3.81	0.40

STATISTICAL INFORMATION DATABASES DEVELOPMENT SUPPORT GUIDE

Maria Helena C. Guerra[1] and Ana Cristina M. Costa[2]

Abstract *— The main objective of the Development Support Guide is to establish procedures to help statistic technicians to construct the Production Database (PDB) and the User Database (UDB) for Portugal's data on the European Community Household Panel (ECHP). These databases are constructed through several steps. The Development Support Guide concerns the imputation and weighting procedures steps as well as the final production of the PDB and the UDB. The PDB and UDB development process is based on specific programs developed by the Statistical Office of the European Communities (Eurostat) with the Statistical Analysis System software (SAS) and C++ programming language applications developed by the University of Michigan. The SAS programs require adjustments every time a new wave (annual survey) is carried out. As a result, with the Development Support Guide it is intended to describe and characterize the SAS programs modifications and the structure of the data files engaged on this process.*

Index Terms — European Community Household Panel, SAS programming, Statistical Information Databases, Statistics Technicians Guide.

INTRODUCTION

Information on income and social indicators is getting more and more relevance to support economic and social policies within the European Union. Consequently, the Statistical Office of the European Communities (Eurostat) decided to implement a longitudinal survey called European Community Household Panel (ECHP).

A panel design allows following up and interviewing the same private households and persons over several consecutive years. The questionnaire of the ECHP gathers information on income, labour, health and other social indicators concerning living conditions of private households and persons.

This information is processed through several steps such as data checking, imputation and weighting. Afterwards, the data is stored in the Production Database (PDB). Based on the PDB a process of anonymisation is carried through and a user-friendly longitudinal User Database (UDB) is constructed.

The purpose of the Development Support Guide is to establish procedures to help statistic technicians to construct the Production and the User Databases for Portugal's data on the ECHP [1]. This document concerns all the mentioned steps to create the PDB and the UDB except data checking.

The next section describes the ECHP and the several stages that lead to the statistical databases construction. After referring the most relevant databases technical issues, the structure and content of the Development Support Guide is presented in detail. The last section points out the main conclusions.

THE EUROPEAN COMMUNITY HOUSEHOLD PANEL

The ECHP is a longitudinal annual survey conducted by Eurostat in cooperation with the National Data Collection Units, witch are National Statistics Institutes or Research Centres from each country. The annual surveys will be referred to as waves. The first wave was implemented in 1994.

The questionnaire development was carried out by Eurostat and a standard version was established. Although a few modifications to the questionnaire were made for each country, the information gathered allows the development of comparable social statistics across Member States on income, labour, poverty and social exclusion, housing, health and other social indicators.

Portugal's National Statistic Institute collects the data by means of the national questionnaire. The raw data is compiled and processed through several stages (Figure 1). In the first stage, data checking, data cleaning and cross wave consistency checks are made. By providing multiple observations on the same individuals, panel data makes possible to reveal some inconsistencies that may damage the quality of the results.

After the data checking, there is the imputation stage where several techniques are employed for a number of crucial variables to minimize the amount of missing data. The imputation is more difficult in panels than in cross-sectional surveys since plausible cross-sectional imputations of a given variable in successive waves may produce a highly implausible measure of change [2]. Then, in the weighting stage, several sample weights are constructed

[1] Maria Helena C. Guerra, Assistant Professor at Instituto Superior de Estatística e Gestão de Informação, Universidade Nova de Lisboa, Campus de Campolide 1070-312 Lisboa, Portugal, helena@isegi.unl.pt
[2] Ana Cristina M. Costa, Assistant Professor at Instituto Superior de Estatística e Gestão de Informação, Universidade Nova de Lisboa, Campus de Campolide 1070-312 Lisboa, Portugal, ccosta@isegi.unl.pt

taking into account the cross-sectional and the longitudinal weights and adjusting the sample distribution to agree with the known distribution of population totals.

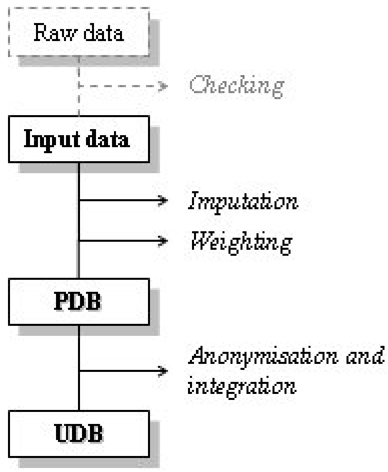

FIGURE. 1
PDB AND UDB DEVELOPMENT STAGES.

After these various stages, the data is stored in the Production Database (PDB). For each wave, this cross-sectional database is composed of four files containing *household register records*, *membership roster records*, *household questionnaire records* and *personal questionnaire records*.

Besides of the complex structure of the PDB files, the information stored is considered confidential. Therefore, a process of anonymisation takes place and a user-friendly longitudinal database is created (UDB).

DATABASES TECHNICAL ISSUES

File Management

The PDB and UDB development process is based on specific programs developed by Eurostat with the Statistical Analysis System software (SAS) and C++ programming language applications developed by the University of Michigan.

Physically, the data files and the SAS programs files are organized in six directories for each wave and three directories common to all waves. There are also SAS programs, C++ applications and other files stored in SAS software directories (for example: *c:\sas*, *c:\sas\sasuser* and *c:\sas\srclib*). The physical organization of all files was setup by Eurostat and any change to the directories structure or file names implies extra modifications to all programs involved.

The approximate number of files involved in the databases development and their functional organization is illustrated in Figures 2 and 3. It is important to point out that as the number of waves increases the file management becomes more complex.

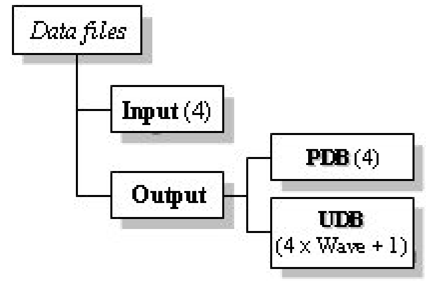

FIGURE. 2
APPROXIMATE NUMBER OF DATA FILES INVOLVED IN THE DATABASES DEVELOPMENT AND THEIR FUNCTIONAL ORGANIZATION.

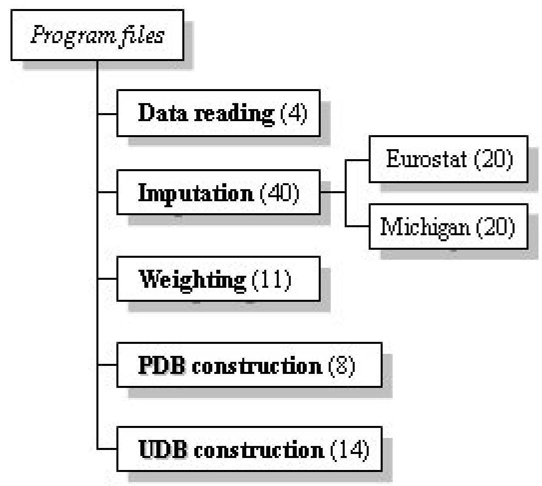

FIGURE. 3
APPROXIMATE NUMBER OF PROGRAM FILES INVOLVED IN THE DATABASES DEVELOPMENT AND THEIR FUNCTIONAL ORGANIZATION.

Program Execution

The program execution sequence follows, in general, the steps described by Figure 1. The way that SAS code was produced does not allow any deviation to this sequence and therefore the running order is extremely important. For example, some programs are run more than once over the process and, during the imputation stage, Eurostat programs are executed alternately with Michigan programs.

THE DEVELOPMENT SUPPORT GUIDE

The main objective of the Development Support Guide is to establish procedures to help statistic technicians on the process of construction of the statistical databases, PDB and UDB, for each new wave. This document describes and characterizes the SAS programs modifications and the structure of the files engaged on that process.

As a complement to Eurostat documentation, this guide constitutes a very useful support for any experienced SAS programmer to make the necessary adjustments to the programs every time a new wave is carried out.

Document Structure

The Development Support Guide is organized in two major sections: *Programs, data files and requirements* and *Program modifications*.

The first one includes:

- Hardware and software requirements
- Software configuration
- Files organization
- Data files description
- Program files description
- External information
- Programs execution sequence

On the second section, all the modifications to the SAS programs are described by program execution sequence. In this part of the document, every time a more complex program adjustment takes place, the text is illustrated with SAS code examples for the fifth wave. Finally, at the end of the document, the most important bibliographic references are listed.

The main sections of the Development Support Guide referred before will be analysed in detail.

Document Content

On the first section, the *Hardware and software requirements* subsection describes the software specifications and the minimum requirements of free disk space, RAM memory and computer processor. The Development Support Guide users must take into account these restrictions in order to construct the statistical databases successfully.

All the software configurations are clearly specified and, for example, when it concerns to the *config.sas* file the necessary changes are explicitly presented on the guide.

In the *Files organization* subsection the information concerning the path and the description of each file is illustrated through a table format and follows the fifth wave situation. The decision of making this kind presentation was due to the fact that there are a great number of files engaged on the databases construction process and because this number increases every time a new wave is implemented. Figure 4 shows a fraction of that tabular form.

The fourth subsection, *Data files description*, summarises the contents of the PDB and UDB files whereas a full description is available on the *ECHP UDB Manual – Waves 1, 2 and 3* [3].

The *Program files description* subsection is organized by program execution sequence:

- SAS programs that convert the input data files in ASCII format to SAS Data Set format
- SAS programs of the imputation stage
- SAS programs of the weighting stage
- SAS programs for PDB construction
- SAS programs for UDB construction
- SAS programs that convert the UDB data files to ASCII format

Directory	Files		Description
. . .			
c:\painel\wav5_imp	capself.sas comprev.sas etape1.sas etape2.sas etape3.sas etape4.sas hhdinp.sas indep.sas nbmonhh.sas nbmontp.sas	netgros1.sas netgros2.sas neth.sas netp.sas persinp.sas rent.sas revinp.sas sample.sas verifh.sas	Imputation SAS programs

FIGURE. 4
FILES ORGANIZATION.

The description of each file includes the program purpose and its subprograms (program executed by other program). Figure 5 illustrates the document text regarding the second program to be executed during the imputation stage (Michigan program *etape1.sas*).

> **<u>Step 2</u> – program ETAPE1.SAS (Michigan)**
>
> The purpose of this program is to impute income variables at individual and household levels.
>
> The ETAPE1.SAS (Michigan) program executes several programs:
>
> ▪ YIMPUTE.SAS – performs the imputation of *Net Monthly Household Income*.
>
> ▪ YIMPUTE1.SAS – performs the imputation of *Self-Employment Income*.
>
> ▪ YIMPUTE2.SAS – performs the imputation of *Capital Income*.
>
> ▪ YIMPUTE3.SAS – performs the imputation of *Rental Income*.

FIGURE. 5
DESCRIPTION OF THE PROGRAM FILE ETAPE1.SAS.

The *External information* subsection specifies which auxiliary information must be provided by the National Data

Collection Units for each wave and also details the structure of the external information control file.

The *Programs execution sequence* subsection presents thoroughly and step by step, the running order procedure of the databases construction. At this point, and for each step, the programs names, their location and a short technical description are indicated. Since the execution sequence is quite complex, it is important to point out that all the information presented in this stage is brief and very precise.

On the second major section, *Program modifications*, the changes to the SAS programs are examined in detail.

All the programs and subprograms are analysed by execution sequence and, for each one, it is mentioned the exact position in the program code where the modification takes place and the exact description of that adaptation. It is important to refer that, at this point, it is also explained the logic process of the modifications. Along the text, SAS code examples for the fifth wave are used to illustrate more complex program adjustments.

The Development Support Guide also draws attention to some efficiency issues. To create the SAS programs for the current wave it is advisable to use as reference the last implemented wave programs to perform the necessary changes. Thus, this process becomes more efficient and the occurrence of programming errors is minimized. Moreover, it is important to write descriptive comments along the SAS code every time an adaptation occurs. This makes easier the program modifications for the next wave.

CONCLUSION

The main objective of the Development Support Guide is to establish procedures to help statistic technicians to construct the Production and the User Databases for Portugal's data on the ECHP. The feedback to this document was positive since it turned out to be very useful for the statistical databases development for the sixth and following waves.

However, the users would like the SAS code to be presented more thoroughly in order to simplify the modification process. Unfortunately, the programs complexity does not allow an exhaustive description of the SAS code. Nevertheless, this guide is intended to be used by experienced SAS programmers and a previous analysis of all programs is advisable.

THE EFFECTS OF DESIGN STUDIO'S PHYSICAL ENVIRONMENT ON ARCHITECTURAL EDUCATION

Elmira Sener[1], Sinan M. Sener[2]

Abstract *— The basis of the architectural education is "architectural design studio" class. In Istanbul Technical University Faculty of Architecture, architectural design studios take place in two kinds of design studios: "single room design studio" and "separated design studio groups in a large classroom".*

The aim of this paper is to investigate the physical characteristics of these two kinds of design studios in terms of learning environment, in which "design process" takes place; to question the relationship between the physical characteristics of the design studio and the interaction of student / tutor; to research about the different consequences of the different physical characteristics of the "single room design studio" and "separated design studio groups in a large classroom" on positive or negative behavior among the students.

In this structure, the study is enriched by a questionnaire, which investigates the experiences of about usage the design studios; conclusions, which can be useful for designing the architectural design studios, are recorded.

Index Terms — Architectural design education, design studio education, design studio's physical environment, student/tutor interaction.

INTRODUCTION

The "architectural design studio course" which is fundamental for architectural education is an applied course where architectural design process is realized artificially. This environment is an educational element in terms of the importance given by the academicians, educational institutions and the time reserved for the course. The architectural design studio in the Istanbul Technical University lasts for four years, which make eight complementary semesters following each other. The "design studio" where the students may choose a different tutor every semester and the tutor educates an average number of 10-15 students is also the name of the classroom.

SCOPE OF THE RESEARCH

The architectural design studio in the Faculty of Architecture of Istanbul Technical University is a period in which the architecture candidate works on a subject on a pre-defined project plot for fourteen weeks and for eight hours a week, in each semester.

The learning process can be driven by the concept of working in teams or groups. Because, creativity can be enhanced by collaboration and cooperation [1]. Thus, collaborative and cooperative works, establish the design studio education.

In I.T.U. Faculty of Architecture, the studio courses take place in two types of physical studio environment: "single room design studio"(Figure-1) and "separated design studio groups in a large classroom"(Figure-2). One or two architectural project groups continue their courses in "the single room design studios" while approximately ten project groups are in the same space in "separated design studio groups in a large classroom".

FIGURE-1 GENERAL VIEW TO "SINGLE ROOM STUDIO"

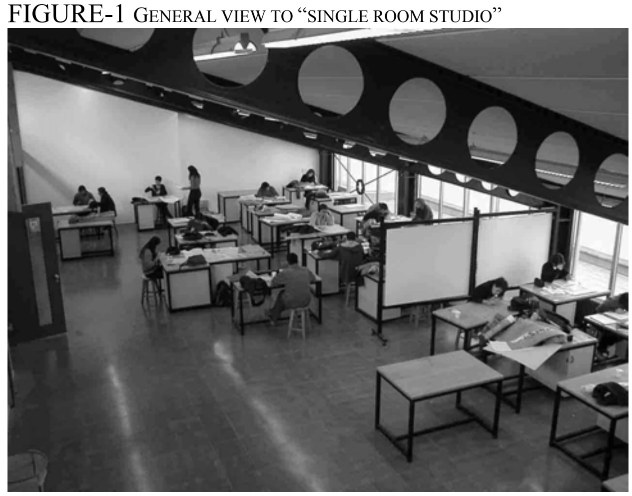

FIGURE-2 GENERAL VIEW TO "SEPARATED STUDIO"

[1] Elmira Sener, Istanbul Technical University, Faculty of Architecture, Department of Architecture, Taskisla, 80191, Istanbul, Turkey, senerel@itu.edu.tr
[2] Sinan Mert Sener, Istanbul Technical University, Faculty of Architecture, Department of Architecture, Taskisla, 80191, Istanbul, Turkey, mert@itu.edu.tr

Thus, it is very important to arrange the spatial and physical capabilities of the project studio in a way to contribute to the project education period, considering that the academic semesters are limited.

RESEARCH OBJECTIVES

In the architectural design, creativity has a very important role like in all the other design educations. The indirect link between design and creativity is established in the studio environment throughout the time in which the first ideas starts to appear. As Candy and Edmonds stresses, it is important to gain experience from past examples, to produce possible methods and strategies out of collected information, to synthesize the visual perceptions and to experience various information in this studio is important [2].

Cuff, evaluates the studio education not only as a "work place" but also as a "home" and a" work place" together, similarly to the contemporary concept of a home-office. The reason of this approach is the fact that the studio education is spread through a long period of time in the education process. Students should perceive the studio as somewhere, which they can work in enthusiastically both in and out of the class hours [3].

The objective is first to observe the physical properties of the above mentioned studio types, the studio space and the sub-compounds of it where the activity of "architectural design" takes place, and second, to cross-examine the relation between the results of communication and interaction of student-tutor depending on the physical properties of the architectural studio space. In existence of a relation, it shall be searched in which way the two studios, by which properties cause which kind of behaviors, and whether they create a discontent. The reason for a trend in spatial choices and the advantages/disadvantages shall also be compared.

RESEARCH METHOD

Within this study, in terms of the above-mentioned educational necessities and spatial properties, a survey design has been conducted among the students who use different types of physical environments. The survey instrument used in the study was a self-designed standardized questionnaire. By analyzing the effect of studio space on the design education, it was tried to reveal their preferences about the studio environment and the physical environment of the space.

In this process, the questionnaire is tested with 174 students. 71 of them were students who use single room design studio, and 103 of them were from separated design studio groups in a large classroom. Information, which can be data for the design of architectural design studios and about the experiences and desires of the students about the studios, has been gathered.

EVALUATION OF THE SURVEY DESIGN

The survey included two groups of students. These were either from a studio where one or two tutors shared the same space, or from a single large studio where up to ten studio groups are divided by separator panels.

Same questions were asked to all the students and their responses and positions were displayed in the graphics below.

It became clear that students from 3-4th semesters mostly study in "single room studios" (35% 6-7th semesters, 65% 3-4th semesters), while in "separated studios", the student ratio of 3-4th semesters to 6-7th semesters is equal (50% 3-4th semesters, 50% 6-7th semesters).

71% of the students who study in "separated studios" are pleased with their physical studio environment and 29% are not pleased, while only 38% of the students who study in "single room studios" are pleased and 62% are not pleased with their environment (figure-3,4).

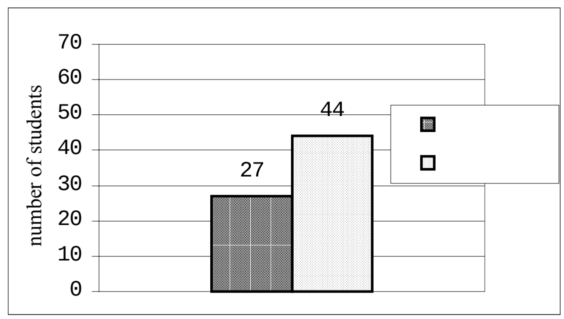

FIGURE-3 PLEASED / NOT PLEASED STUDENTS IN"SINGLE ROOM STUDIOS"

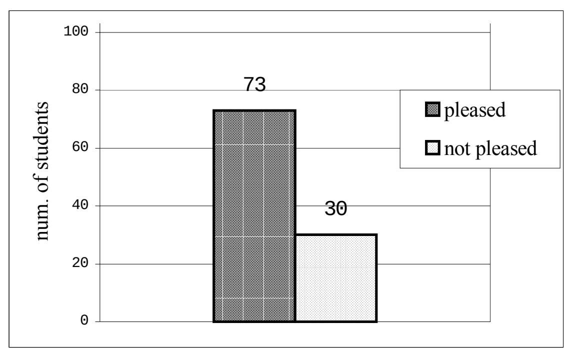

FIGURE-4 PLEASED / NOT PLEASED STUDENTS IN "SEPARATED STUDIOS"

Student Preferences on Studio Environment

When the students of "single room studio" group were asked in what type of a studio they would like to attend their courses, 27% preferred "single room studio", 30% preferred "separated studio", 33% preferred "personalized space in separated design studio", 7% preferred virtual (reality) studio and %3 answered the choice as "other".

For the students of "separated studio" group, 13% preferred "single room studio", 60% preferred "separated studio", 14% preferred "personalized space in separated design studio”, 10% preferred virtual (reality) studio, and 3% answered the choice as “other”.

Studio Environment Effects on Tutor-Student Relation

When it is questioned what affect the studio space has on the tutor-student relationship, it drew our attention that the output of the survey was the same for two groups. 47% of the students suggested that the studio space did not have any contribution to their interaction with the tutors while %29 suggested that the space was a positive factor and 24% suggested just the opposite.

The Existence of Separators in the Studio Environment

In case the separator panels between different project groups inside the large classroom were removed, %7 of the single studio’s students thought it would be positive, 66% said it would be negative, 12% suggested it would not make any difference, 12% expressed that it would confuse them and 3% told they would feel more relieved (figure-5).

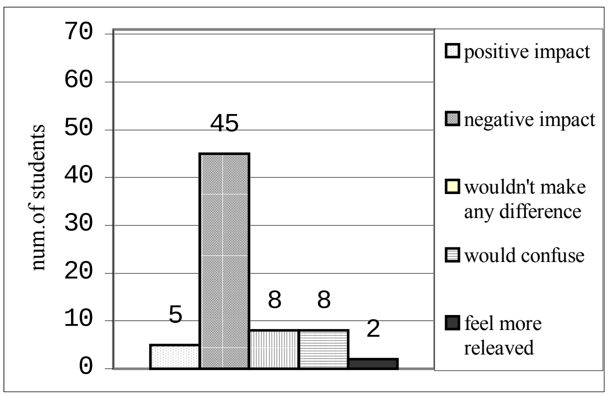

FIGURE-5 IMPACTS OF SEPARATORS ON SINGLE ROOM STUDIO STUDENTS’

On the other hand when the students of separated studio were asked the same question, 4% of the students thought it would be positive, 73% said it would be negative, 9% suggested it would not make any difference, 12% expressed that it would confuse them and 2% told they would feel more relieved (figure-6).

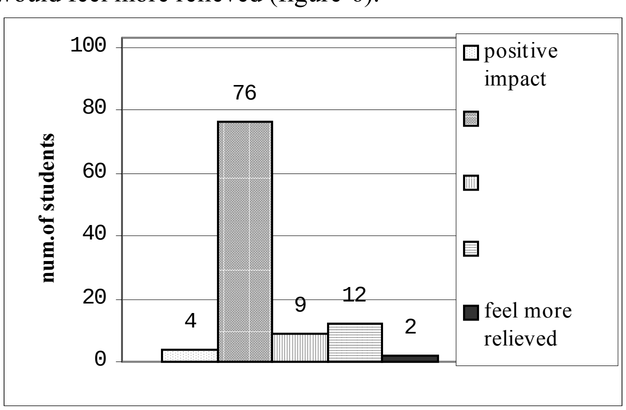

FIGURE-6 IMPACTS OF SEPARATORS ON SEPARATED STUDIO STUDENTS’

Single Room Design Studio’s Advantages and Disadvantages

According to the survey, when the students of a single room studio were asked about the advantages of single room studio, 29% of them chose sincerity, 23% chose individualization of the space, 23% chose quietness, 2% chose prevention of distraction, 2% chose benefits of separator panels and 1% chose “other”(figure-7).

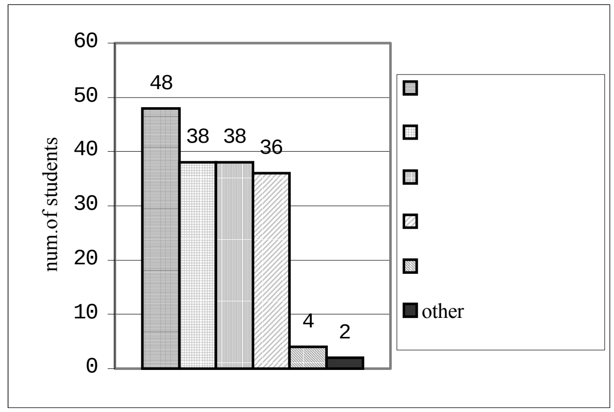

FIGURE-7 ADVANTAGES OF “SINGLE ROOM STUDIOS” ACCORDING TO STUDENTS OF “SINGLE ROOM STUDIOS “

When the students of separated studios evaluated the advantages of single room studios, 24% of them chose sincerity, 21% chose individualization of the space, 24% chose quietness, 26% chose prevention of distraction, 4.5% chose benefits of separator panels and 0.5% chose “other” (figure-8).

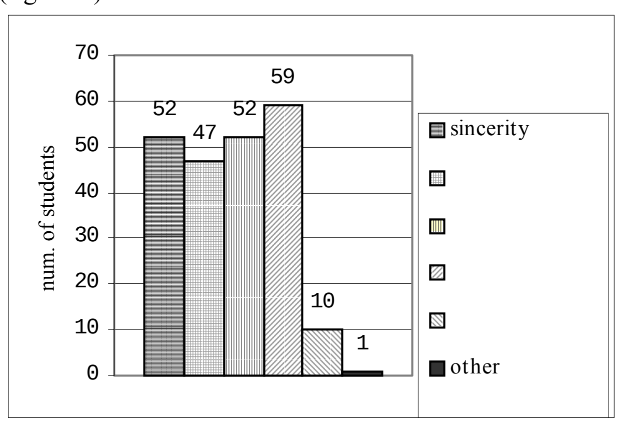

FIGURE-8 ADVANTAGES OF “SINGLE ROOM STUDIOS” ACCORDING TO STUDENTS OF “SEPARATED STUDIOS”

On the other hand, when the students of a single room studio were asked about the disadvantages of the single studio, 25% chose unawareness of other groups works, 2% chose quietness of the space, 20% chose lack of communication with friends in other groups, 21% chose inconvenience or distress due to small space, 19% chose negative effect of insufficient air, 12% chose feeling too much control of the tutor and %1 chose as “other”.

For the students of a separated studio, 23% chose unawareness of other groups works, 4% chose quietness of the space, 19% chose lack of communication with friends in other groups, 20% chose inconvenience or distress due to small space, 19% chose negative effect of insufficient air, 14% chose feeling too much control of the tutor and 1% chose as "other".

Separated Design Studio's Advantages and Disadvantages

The size of the studio space was also questioned within the survey study. Assuming that their studio type was separated studio, first the students of single room studios chose the advantages of largeness in an order. According to the results, 34% chose awareness of other groups works, 30% chose visual communication with other groups, 27% chose flexibility of space reserved for any group, 7% chose less control of the tutor and 2% chose as "other"(figure-9).

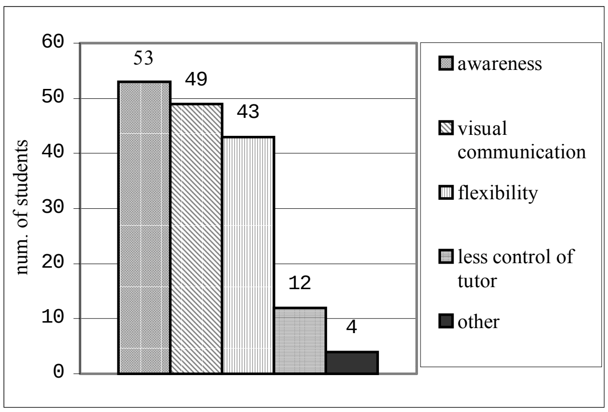

FIGURE-9 ADVANTAGES OF "SEPARATED STUDIOS" ACCORDING TO STUDENTS OF "SINGLE ROOM STUDIOS"

When the students of separated studios were asked to choose the advantages, 31% chose awareness of other groups works, 32% chose visual communication with other groups, %26 chose flexibility of space reserved for any group, 9% chose less control of the tutor and 2% chose as "other"(figure-10).

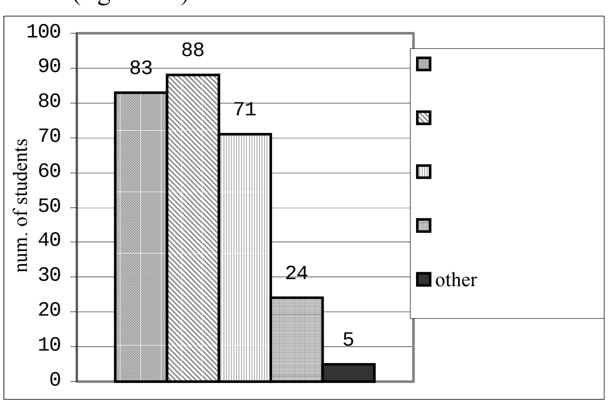

FIGURE-8 ADVANTAGES OF "SEPARATED STUDIOS" ACCORDING TO STUDENTS OF "SEPARATED STUDIOS"

When it came to thinking the disadvantages of a separated studio, 32% of the students of single room studios chose distraction of attention while 38% chose noise, 4% chose low temperature in studio, 6% chose interior breeze or wind, 19% chose distraction of tutor and %1 chose as "other"(figure-11).

For the disadvantages of separated studios, 27% of the students of separated studios chose distraction of attention, 40% chose noise, 7% chose low temperature in studio, 7% chose interior breeze or wind, 17% chose distraction of tutor and 2% chose as "other"(figeure-12).

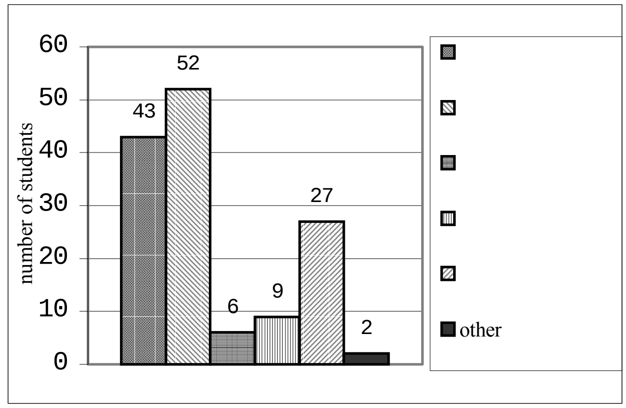

FIGURE-11 DISADVANTAGES OF "SEPARATED STUDIOS" ACCORDING TO STUDENTS OF "SINGLE ROOM STUDIOS"

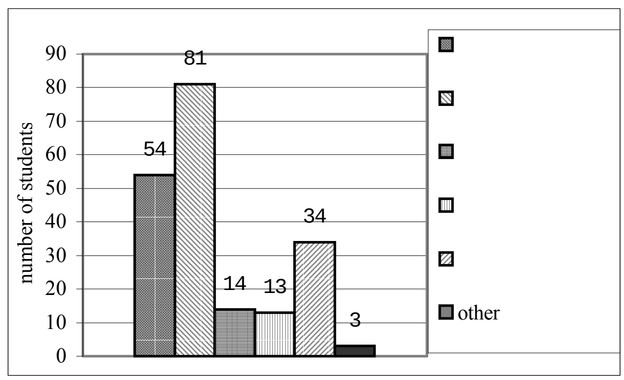

FIGURE-12 DISADVANTAGES OF "SEPARATED STUDIOS" ACCORDING TO STUDENTS OF "SEPARATED STUDIOS"

GENERAL EVALUATION

While the students of separated studios are pleased with their spaces on a high percentage, this percentage is lower for the students of single room studios.

Another general result is that, the students of separated studios mostly prefer studying in the same type of studio, but the students of single room studios desire individualized space inside a separate studio at the first place. Their second and third choices were a separated studio and their own – single room studio-, respectively.

All test subjects thought that the physical environment in their studio did not contribute to the interaction between the students and the tutors.

All test subjects agree that the separator panels are important and positive elements.

The common view of both student groups is that "a separated design studio group in a large classroom with individualized spaces" is the best for them. But it was also seen that a flexible arrangement of space inside single room design studios would enhance their satisfaction with the studio.

While the most important aspect of a design studio for the students of separated studios is "visual communication with other groups", this choice leaves its place to "awareness of other groups" in a single room studio group. As a matter of fact, the students of single room studios have grown to ignore the importance of visual communication, which they already lack. In order to increase creativity inside the studio, the students prefer a freedom of perception at their own will and timing, instead of visual and cognitive isolation.

Although the separated design studio groups in a large classroom is mostly preferred by students, this model is also blamed for poor acoustics and distraction of attention of both students and the tutors.

The preferred aspects of the single room studios are spatial sincerity, individualization, quietness and prevention of distraction. On the contrary, both group of students state that distressing or boring size of space and unawareness and lack of communication with other groups is important disadvantages.

CONCLUSION

The contribution of design studio, which is a touchstone for architectural education, is obvious. This survey, which searches effect of "single room design studio" and "separated design studio groups in a large classroom" type of studios and their spatial organization, on the student-tutor behaviors, depicts the positive and negative aspects of these spaces. The likes and dislikes of the students about a studio appears more clearly. Consequently, as the results have shown the dilemma or duality on this matter with both advantages and disadvantages, it was evaluated that both types of studios should exist in terms of variety in architectural education. As a general comment, it is natural that students who have not used the possibilities of a flexible type of studio may require other spaces, which belong to themselves or small groups.

It would not be wrong to say that the students' choice agrees with the "separated large design studio groups in a large classroom" type of studio provided that; acoustical comfort is maintained, individualization and belonging is easily created via mobile panels, it is always possible to interact with other groups depending on their choice and flexible use is supported.

ANÁLISE DAS INTERFACES DOS SIMULADORES DIGITAIS E SUAS APLICAÇÕES

Alisson Moisés Moreira de Souza[1]*, Ana Cristina C. Lyra*[2]

Resumo *— A simulação digital mostra-se como importante ferramenta para desenvolvimentos e para aprendizagem. Trata-se de análise de diferentes interfaces homem-máquina usadas nos simuladores digitais e suas aplicações. É simulada a partida da máquina de indução. São consideradas três ambientes de simulação: o "prompt" de comandos do Mat Lab; o Simulink usando diagramas de simulação analógica; e modelos padronizados na biblioteca Power System , MatLab 6.12/Simulink*

O ambiente de "baixo nível" (prompt) exige familiaridade com modelos matemáticos, indicado ao ensino de modelagem e integração numérica, ou ao desenvolvimento de modelos inéditos, exigindo poucos recursos computacionais. A linguagem de simulação analógica permite estruturar e personalizar os modelos, o que é útil no processo pedagógico. Finalmente, o uso de modelos padronizados (Tool Box) exige pouca habilidade com modelagem, substituída pela familiaridade com a implementação de bancada, aplicando-se, geralmente, à exploração de propriedades macroscópicas dos modelos. Por outro lado, exige abundantes recursos computacionais.

INTRODUÇÃO

O uso de simuladores digitais é hoje uma realidade para os engenheiros. Seja na construção de máquinas elétricas , na indústria automobilística, nas faculdades e até na economia, a simulação digital mostra-se como importante ferramenta nos processos de desenvolvimento e de aprendizagem. Torna-se possível prever situações indesejadas, antecipar decisões, dimensionar parâmetros ou, simplesmente, explorar propriedades dos sistemas em simulação, garantindo economia de tempo e dinheiro.

Análisam-se três diferentes interfaces homem-máquina usadas nos simuladores digitais e suas aplicações na engenharia, em especial na elétrica.

A historia dos simuladores digitais quase se mistura com a historia da programação. A simulação digital apareceu dentro das grandes universidades como ferramenta aplicada ao estudo de sistemas físicos ou matemáticos, para explorar propriedades e validar teorias, geralmente em situações associadas à pesquisa ou ao desenvolvimento, que exigiam número elevado de cálculos, inviáveis até então. Com poucos, e caros, recursos computacionais, a simulação digital possuiu uma infância bem difícil, com interfaces bastante desconfortáveis ao usuário, próximas ao nível de abstração da máquina. Rapidamente, grandes laboratórios e grandes empresas vislumbraram o potencial da simulação digital para o desenvolvimento e para a pesquisa.

Com o desenvolvimento das linguagens de programação e a expansão dos recursos computacionais, a simulação digital também se desenvolveu, aumentando a proximidade com o usuário e o grau de especialização.

Hoje, com o mercado de software consolidado, existem inúmeros simuladores digitais voltados a cada área especifica, em diferentes níveis de proximidade com o usuário e de acordo com cada aplicação.

METODOLOGIA

A metodologia adotada foi a simulação do modelo matemático da máquina elétrica de indução trifásica em diferentes interfaces de simulação em três níveis de proximidade com o usuário, usando, para isto, o software MatLab 6.12 e seus pacotes.

A primeira interface, ou linguagem, de baixo nível de proximidade com o usuário, refere-se ao "prompt de comandos" do MatLab 6.12. A segunda interface refere-se a diagramas de simulação analógica usando o pacote *Simulink,* também no MatLab 6.12, em ambiente gráfico.

A última interface análiseada, de alto nível de proximidade com o usuário, refere-se ao ToolBox

da biblioteca Power System, também no *Simulink*, MatLab 6.12, onde a modelagem é implementada em ambiente gráfico com modelos padronizados ou pré-formatados.

MODELAMENTO MATEMÁTICO

O modelo matemático utilizado é o modelo da máquina de indução trifásica alimentada via estator, escrito na referência síncrona através de eixos ortogonais conhecidos por dq. As simulações consideram uma máquina de indução de 3hp.

O conjunto de equações diferenciais que sintetiza o modelo é listado a seguir. As equações de (1) a (4) são as equações elétricas de estator e rotor, compostas pelas parcelas ôhmicas e indutivas nos enrolamentos.

A equação (5) representa o acoplamento entre as correntes e os fluxos magnéticos da máquina de indução. Finalmente, as equações (6) e (7) representam o torque eletromagnético gerado, juntamente com acoplamento mecânico do momento de inércia e a carga mecânica aplicadas ao eixo.

Embora haja sete equações, matematicamente, tem-se um sistema diferencial não-linear de 5ª ordem: duas equações de estator, duas equações de rotor e uma equação mecânica.

$$estator\begin{cases} v_{qs} = \frac{1}{\omega_b}\cdot\frac{d\varphi_{qs}}{dt} + \frac{\omega}{\omega_b}\cdot\varphi_{ds} + r_s\cdot i_{qs} & (1)\\ v_{ds} = \frac{1}{\omega_b}\cdot\frac{d\varphi_{ds}}{dt} - \frac{\omega}{\omega_b}\cdot\varphi_{qs} + r_s\cdot i_{ds} & (2)\end{cases}$$

$$rotor\begin{cases} v'_{qr} = \frac{1}{\omega_b}\cdot\frac{d\varphi'_{qr}}{dt} + \frac{(\omega-\omega_r)}{\omega_b}\cdot\varphi'_{dr} + r'_r\cdot i'_{qr} & (3)\\ v'_{dr} = \frac{1}{\omega_b}\cdot\frac{d\varphi'_{dr}}{dt} - \frac{(\omega-\omega_r)}{\omega_b}\cdot\varphi'_{qr} + r'_r\cdot i'_{dr} & (4)\end{cases}$$

Matrizfluxo-corrente

$$\begin{bmatrix} i_{qs}\\ i_{ds}\\ i'_{qr}\\ i'_{dr}\end{bmatrix} = \begin{bmatrix} a & 0 & b & 0\\ 0 & a & 0 & b\\ b & 0 & a & 0\\ 0 & b & 0 & a\end{bmatrix}\cdot\begin{bmatrix}\varphi_{qs}\\ \varphi_{ds}\\ \varphi'_{qr}\\ \varphi'_{dr}\end{bmatrix} \qquad (5)$$

$$\begin{cases} \textit{Equação}\text{ do Torque Eletromagnético}\\ \tau_{ele} = \frac{3}{2}\cdot\frac{X_m}{\omega_b}\cdot\left(i_{qs}\cdot i'_{dr} - i_{ds}\cdot i'_{qr}\right) & (6)\\ \textit{Equação}\text{ mecânica}\\ \frac{d\omega_r}{dt} = \frac{1}{J}\left(\tau_{ele} - T_c\right) & (7)\end{cases}$$

LEGENDA DAS VARIÁVEIS DAS EQUAÇÕES

v_{qs}	tensão do eixo q do estator;
v_{ds}	tensão do eixo d do estator;
v'_{qr}	tensão eixo q de rotor refletida no estator;
v'_{dr}	tensão eixo d de rotor refletida no estator;
r_{qs}	resistência do eixo q do estator;
r_{ds}	resistência do eixo d do estator;
r'_{qr}	resistência eixo q de rotor refletida no estator;
r'_{dr}	resistência eixo d de rotor refletida no estator;
i'_{qr}	corrente eixo q rotor refletida no estator;
i'_{dr}	corrente eixo d rotor refletida no estator;
i_{qs}	corrente do eixo q do estator;
i_{ds}	corrente do eixo d do estator;
Ψ_{qs}	fluxo por segundo do eixo q do estator;
Ψ_{ds}	fluxo por segundo do eixo d do estator;
Ψ'_{qr}	fluxo por segundo do eixo q do rotor refletido no estator;
Ψ'_{dr}	fluxo por segundo do eixo d do rotor refletido no estator;
ϖ_b	freqüência base da rede de alimentação do estator;
ϖ	freqüência da referência genérica utilizada no modelo, no caso a freqüência síncrona;
ϖ_r	freqüência mecânica do rotor;
J	momento de inércia do eixo do rotor;
T_c	torque de carga.
X_m	reatância mútua entre estator e rotor;

$$b = \frac{X_m^{\ 3} - X_{lm}^{\ 2}\cdot X_m}{X_{lm}^{\ 4} - 2\cdot X_{lm}^{\ 2}\cdot X_m + X_m^{\ 4}}$$

$$a = \frac{X_{lm}^{\ 3} - X_{lm}\cdot X_m^{\ 2}}{X_{lm}^{\ 4} - 2\cdot X_{lm}^{\ 2}\cdot X_m + X_m^{\ 4}}$$

O modelo matemático é aplicado às diferentes interfaces de simulação. A variável de saída análiseada é a velocidade durante a partida.

INTERFACE DE BAIXO NÍVEL: "PROMPT" DE COMANDOS DO MATLAB 6.12

Nesta interface, a programação do modelo é feita reescrevendo as equações diferenciais em forma de equações de estado, para permitir a utilização de métodos numéricos de integração. O método numérico de integração utilizado é o método de Euler Modificado.

A linguagem de programação é composta de uma seqüência de comandos estruturados no "prompt" do MatLab 6.12. Trata-se de linguagem semelhante à linguagem C, permitindo estruturas de programação do tipo *for , if, while*, entre outras.

Em primeiro lugar definem-se os parâmetros da máquina elétrica: resistências, indutâncias, momento de inércia, carga nominal, freqüência base, etc. A seguir, inicializam-se as variáveis do programa, como as correntes, a velocidade, torque, fluxos magnéticos, tempo e outras variáveis auxiliares.

Então, entra-se no loop das iterações, uma estrutura do tipo *for*, começando com t=0 até o tempo final de simulação, onde o sistema diferencial é resolvido passo a passo.

Dentro do *for*, calcula-se cada derivada das variáveis de estado, no caso, os fluxos magnéticos e a velocidade. Então, integra-se cada variável de estado, usando uma aproximação linear (Euler Modificado). A seguir calculam-se as correntes e, a partir destas, o torque. Finalmente, consegue-se a velocidade. Isto é feito para cada incremento da variável tempo, cujo passo é 1ms. A cada passo, a velocidade e outras variáveis de interesse (torque, tensões e correntes) são armazenadas em estruturas do tipo vetor de dados, conhecidas como *Array*.

Segue, abaixo, o conjunto de comandos responsável pela simulação do modelo, nesta interface.

INTERFACE : DIAGRAMAS DE SIMULAÇÃO ANALÓGICA (MATLAB 6.12/SIMULINK)

Este tipo de interface foi muito consagrado entre as aplicações de controle de sistemas, dada sua proximidade com a implementação dos sistemas de controle através de elementos analógicos e sua capacidade de sintetizar propriedades do sistema de maneira visual.

Nesta interface também é preciso reescrever as equações diferenciais na forma de equações de estado. A seguir iniciou-se a construção dos diagramas de simulação analógica a partir dos elementos do pacote Matlab 6.12/Simulink. São utilizados blocos que representam as operações matemáticas das equações de forma visual. Nestes diagramas, pode-se representar operações lineares como soma, ganho, integração, diferenciação; operações não-lineares como o produto entre duas variáveis de estado; ou mesmo os termos não-homogênenos das equações como fontes e o torque de carga, através de entradas senoidais ou degraus no domínio do tempo.

Cada equação de estado é montada e transformada em um bloco fechado, formando um sub-diagrama. Existem quatro blocos, um para as equações de estator, um para as equações de rotor, um para a equação mecânica e um para matriz corrente-fluxo.Pode-se visualizar a seguir o bloco da equação mecânica.

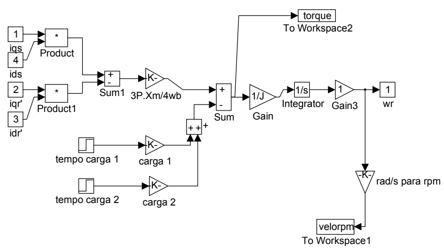

FIGURA.1
EQUAÇÃO MECÂNICA

Então, cria-se um modelo de simulação estruturado e sintetizado através do agrupamento destes sub-diagramas, formando o diagrama de simulação principal, o produto final.

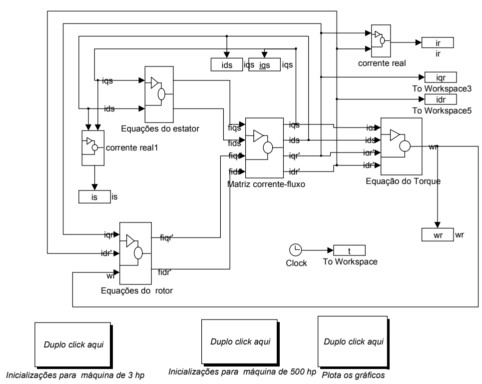

FIGURA.2
DIAGRAMA DE SIMULAÇÃO PRINCIPAL

INTERFACE DE ALTO NÍVEL : BLOCOS PRÉ-FORMATADOS (BIBLIOTECA POWER SYSTEM, MATLAB 6.12/SIMULINK)

Este tipo de interface, de alto nível de proximidade com o usuario, torna o processamento praticamente transparente e, portanto, não é preciso reescrever as equações. Na verdade, neste caso, não é preciso nem mesmo conhecê-las, já que o modelo da máquina de indução é padronizado pelo software.A construção do modelo é iniciada utilizando os elementos oferecidos pela biblioteca Power System do Simulink. Os blocos utilizados são os elementos que seriam utilizados para implementação pratica em um laboratório: a máquina de indução, uma fonte trifásica, a carga mecânica e, finalmente, o osciloscópio.

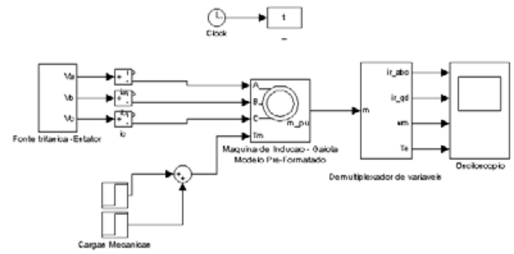

FIGURA.3
DIAGRAMA DE SIMULAÇÃO DE ALTO NÍVEL

RESULTADOS

A seguir, o modelo da máquina de indução trifásica é simulado a partir das três interfaces, fornecendo, como variável de análisee, a velocidade. É simulada a partida da máquina nas seguintes condições: a máquina, de 3hp, é partida em vazio, nas condições de tensão e freqüência nominais até que a velocidade de regime seja atingida. Então, é adicionada ao eixo carga mecânica de valor nominal, aguardando a nova velocidade de regime. Finalmente, adiciona-se uma segunda carga mecânica, também de valor nominal. Como havia de se esperar, todos os modelos forneceram os mesmos resultados de saida.

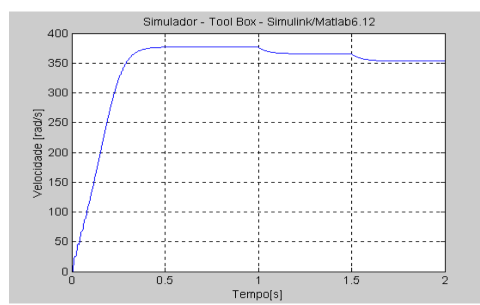

FIGURA.4
SIMULAÇÃO 1 – ALTO NÍVEL

FIGURA.5
SIMULAÇÃO 2 – DIAGRAMA SIM.ANALÓGICA

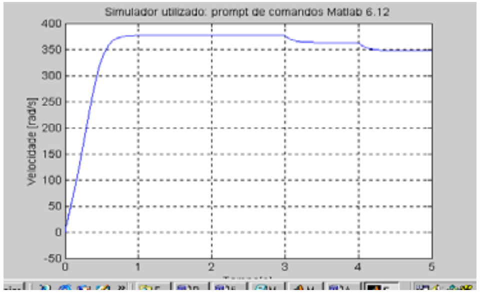

FIGURA.6
SIMULAÇÃO 3 - BAIXO NÍVEL

CONCLUSÕES

Conclui-se que o ambiente de "baixo nível" (prompt do MatLab) exige familiaridade com os modelos matemáticos, sendo indicado ao ensino de modelagem matemática e métodos numéricos de integração. Aplica-se, ainda, à pesquisa de modelos inéditos, onde a padronização não é bem vinda.

A linguagem de simulação analógica exige também habilidades com os modelos matemáticos, permitindo personalizá-los e estruturá-los, o que é útil no processo pedagógico.

Já o uso de simuladores de alto nível de proximidade com o usuário (no caso, Tool Box, MatLab 6.12/Simulink) exige pouca habilidade com modelagem, que deve ser substituída pela familiaridade com a implementação de bancada e aplica-se, geralmente, à pesquisa com elementos clássicos, disponíveis no programa.

Aplica-se também à exploração de propriedades macroscópicas dos modelos. Por outro lado, exige abundantes recursos computacionais e permite pouco domínio do processamento dos modelos em sim4ulação.

Nota-se grande tendência ao uso de simuladores de alto nível, especialmente em aplicações comerciais e nos processos produtivos, onde a padronização e o tempo de desenvolvimento são fatores cruciais. Por outro lado, a padronização aplicada à modelagem pode prejudicar o processo criativo aplicado ao desenvolvimento cientifico, na medida em que não permite mudanças matemáticas estruturais, presentes nos simuladores digitais de baixo nível.

Deste modo, o uso de simuladores digitais no processo pedagógico deve ponderar o nível de proximidade com o usuário aplicado ao modelamento a fim de permitir uma formação ampla, preparando fundamentos necessários aos futuros cientistas, importantes para o desenvolvimento cientifico e, ao mesmo tempo, profissionais que serão absorvidos pelo mercado produtivo.

THE PRINCIPLES OF DOCTRINE FORMATION OF ENGENEERING EDUCATION IN RUSSIA

Yuri Pokholkov[1], Boris Agranovich[2]

***Abstract**: In the report the systems analysis of the causes is conducted and the objective necessity of radical changes in higher engineering education is shown, the main principles for elaboration of national doctrine of engineering education are formed.*
The principles examined in the report include the following groups:
***general-system** principles of formation of the doctrine of engineering education;*
***the principles of formation** of the requirements to engineering activity of the future;*
***principles** of formation of the contents of engineering education; principles of transition on new educational technologies in engineers training;*
***support principles** of quality of engineering education on the socially important level.*
In the report the mentioned above principles are in detail parsed and the concrete examples of their implementation in engineering high schools of Russia are given.

Introduction: Russian Association of Engineering Education (RAEE) and Russian leading technical universities design the principles of formation of the national doctrine of engineering education.

RAEE represents the all-Russian public affiliation of the teachers, engineers and specialists of engineering higher educational establishments, research entities, firms, industry, technical exhibitions, and other organizations interested in development and perfecting of engineering education. For implementation of mission, achievement of object in views and the solution of authorized problems the Association has the departments in 57 regions of Russia and is one of the leading public formations determining the policy of engineering education, ensuring cooperation, with the domestic and foreign partners, state and public organizations.

The contents of the national doctrine of engineering education is determined by a number of the steady tendencies in the world development, change of the social and economic basis of the country, as well as by establishment of new educational values.

To major factors of the world development essentially influencing technical-engineering education, one should attribute the formed imperative "of «survival rate" of mankind and transition to « the model of steady development » of a civilization, globalization of economics and its transition on a technological way of development with the dominance of science and education intensive technologies, and also formation on this basis of a new way of life whose economics and society are based on knowledge. The scale of the mentioned above current economical and social changes in the world demands absolutely new approaches to education and specialist training. The national doctrine of engineering education in these conditions should imply formation in a country of distributed multicultural scientific - educational medium on the international level; openness of the students towards realities of the interdependent world; creation of labor force, competitive at a global level; dilating of understanding of own and other cultures, religions, political systems; development of students' global vision of the world, and also skills indispensable for formation of grounded and weighting judgments on the problems of the contemporary world.

The change of social and economic basis and admission (acknowledgement) of Russia as a country with market economy, realization of [1]necessity of transition to antropoeconomics have generated in Russia and the former union republics complex political, social and economic, social and cultural processes, connected with structural rearrangement of production, development of regional economicses and providing them with specialists for the vital areas of industry, social life, science, culture and education. The economical growth that has begun in Russia and integration of national economy into global economical processes has resulted in formation of the market of intellectual labor and intellectual production. Intellectual labor and production competition in the regional, national and global market faces engineering education with the number of specific problems concerning both satisfaction of the market demand for the specialists in the field of science and engineering, and establishment and development of university of corresponding scientific - educational medium. The strategy of university development should be in this respect directed at training of competitive specialists who are socially protected by the quality and professional opportunities of their education, and also completely personally prepared to work in permanently changeable conditions, which is the essential characteristic of the XXI century.

The new educational paradigm as the basic mechanism of maintenance "of «survival rate" of mankind and steady development of a civilization should be strategically oriented at development of personal features and faces us with the necessity of person-oriented

---

1.Pokholkov Yuri Petrovich, President of, rector of Tomsk polytechnic university, Russia, 634034,. Tomsk, Lenin St, 30, ph. (3822) 415-830, rector@tpu.ru
2. Agranovich Boris Lvovich, chief of Informational - analytical center of Russian Association of Engineering Education, Russia, 634034, Tomsk, Sovetskaya street, 86, Institute Cybernetic center, ph. (3822) 415-502, abl@cc.tpu.edu.ru

professional education whereby personal aspects of professional activity are deliberately pointed out as meaningful and essential for engineer's work and engineering as a whole; demands strengthening of links between education and culture, drastic increase of the specialists' creative potential , strengthening of fundamental specialist training, determines priority development of the university type of the higher technical education, which fully meets the new tasks of civilization development and personal features formation.

Analytical study conducted by the experts of the above reviewed conditions and factors essentially influencing engineering education, and also public expertise of strategies and development directions of engineering education allow forming the main principles of the national doctrine.

General-system principles of formation of the doctrine of engineering education

The doctrine of Russian engineering education represents the system strategic solution determining the purposes and values, policies and main directions of rearrangement and further development of Russian engineering education in response to social,economic, technological and other challenges of the XXI century. The doctrine should provide the basis for elaboration of the contents of engineering education, selection of new educational technologies, permanent support on socially important level of quality of engineering education, maintenance of measures of social and state security of the country and competitiveness in the global market, and a number of other factors. The analysis of the factors determining development of engineering education, demonstrates, that the doctrine elaboration should base on:

analysis of cardinal reformist shifts in the technological and social and economic sphere on the threshold of XXI century (steady development, imperative "of «survival rate" of mankind, antropoeconomics, technological development, formation of educational society,development of complex multidisciplinary sciences, informatisation and mediatisation of all spheres of activity, cross-cultural activity, etc).

prognosis of substantial and structural changes in production, science and culture of the country and educational demands of the population;

research of the processes of transition from raw economy to intellectual, the formation of multistructural economy of the country, the development of regional economies and the problems of globalization of economy;

the systematic conception of the goals and values of the engineering activities of the future;

taking into account the **changes** in the meaningful content and new philosophy of the professional education;

analysis of the condition and dynamics of the market of engineering labor and intellectual products on the regional, interregional, national and international levels.

Taking into account the role of the personal organization of the professional engineer in forming the engineer's mind, in his personal way of entering the engineering culture, his desire for self-improvement and development of his professional skills.

It is vital that the doctrine of engineering education should show the realization of the ideas, written in the National Doctrine of education of the Russian Federation, which aim is to make education the means of public development and of forming the contemporary type of economical relations and State organization.

The fact that in the conditions of awareness of the need to make scientific and intellectual technologies of first priority the engineers are becoming the main figures in the social and economical sphere of society, is of great importance for the formation of the doctrine of engineering education. This puts special responsibility for the definition of the existing and coming problematic situations in engineering education, for the complete formation of the problem-oriented purposes of the doctrine, for the efficiency and quality of the proposed ways of development and for the content of the measures, aimed to implement these goals. It is known that inaccurate or mistaken determination of the problematic situations on the first stages of the social project may lead towards the number of measures, which will not provide the solving of the real problems and which may be fraught with serious consequences in the future.

The content of the doctrine is formed taking into account the fact that education refers to the sphere of national strategical interests of Russia.

The principles of forming of the requirements to the engineering activity

The above-mentioned general principles of the forming of the national doctrine of the engineering education determine the system (planning sphere), which pose the strong requirements towards the end products of the engineering activity. The end product of the engineering activity is represented by the complex of the engineering-technical, engineering-economic, administrative, ecological, etc. project decisions on creating the artificial environments, correspondent to the requirements of the system of planning. The determination of the content of end products of engineering activity and system of planning allow to form the global net of engineering activity and to decompose it into the system of sub-goals, using the well-developed heuristic procedures and models.

The forming of such systematic description of the engineering activity is provided by the experts, using the methods of systematic projecting, the advanced procedures of working with experts and information processing.

Further decomposition of the main goals according to the requirements of the planning system, structure of the engineering activity, and the work of the experts on assessment of futility, completeness, the importance of determined purposes and values, functions of engineering activities, their ranking and aggregation should allow to form a normative variant of goals, functions and structures of engineering activities in the future, which will form a basis of engineer's training.

Usually such structures contain several thousands of elements that are why generation, storage, actualization, and navigation along such a structure, together with the analysis and forming of the project decisions require the use of special informational and program provision.

We assume that this system of requirements, described as a tree of goals of engineering activities, should be transformed into the requirements for the level of efficiency of those, who have finished the program of education of the specialty, and should be included into the Russian state educational standard.

The principles of forming the content of engineering education

The analysis of the requirements towards the engineering activities of the future, presented in the form "Tree of Goals", allows developing the principles of forming the content of engineering education.

The content of engineering education should include the fallowing fractally organized combination [1,2]:

training, which provides mastering of the humanitarian and social-economical, mathematical and natural science, general and vocational knowledge of the required level;

education, which provides, together with training, the forming of methodological culture of the graduate, mastering of the methods and ways of cognitive and professional, communicative and axiological activities on the required level;

habilitation, which provides, together with training and education, the complex preparation of the graduate for the professional activity, and also his professional self-actualization.

For the graduate to become a real professional engineer he needs to leave the educational environment for the real life. Knowledge and methods of his activity should be united into the system, where certain key values serve as the systematizing factor.

The peculiarity of the system of knowledge of engineers training is based on the knowledge of natural-science, mathematics and world outlook, on the breadth of interdisciplinary systematically integrated knowledge of nature, society, thinking, and the high level of general and special vocational knowledge, that provide the ability to act in the problematic situations and solve the problem of training of the specialists with high creative potential.

The bases of engineering education should contain not only the subjects, but also the ways of thinking and acting, in other words the reflective procedures. Knowledge and methods of learning and acting should be joined into the one unity. All these factors arouse the need to include the questions of forming the methodological culture, together with the methods of cognitive, professional, communicative and axiological activity into the requirements for the content and level of engineers training.

The distinguishing feature of the engineering education should involve a high level of methodological culture and a superb creative possession of cognition and activity.

The specialists' training experience shows the success of the engineers' activity which is mostly determined not only by the high level of knowledge and fruitful possession of methods of cognition and activity but also by the integrated preparation for professional work. Not only the preparation for professional activity in normal life conditions and exquisite manufacturing should be taken into account but also ordeals, change of lifestyle, repeated change of one's ideas, viewpoints and philosophy of life may play a vital role. Thus, successful professional activity implies not only a high level of teaching and education but also a mental, psychological and physical culture of a man. An institute of higher education in this respect should become not only the scientific and the educational center, but also the center for one's habilitation, one's professional formation and self-actualization.

Planning the concept of education and the demands for engineering training level, it is crucial to find space for the system of knowledge and methods designed to solve the issues of self-cognition and self-actualization of an individual.

It is very important that the engineering education should be more humanitarian, fundamental and professional.

The meaningful feature of engineering education humanitarization is the provision of harmonious unity of natural-scientific and humanitarian culture of cognition and activity, the unity based on mutual understanding and dialogue.

The most important task of the engineering education system in this respect implies creating the conditions of the revival of a united natural-scientific and humanitarian culture of cognition and activity.

The educational concept could become more fundamental by means of broadening and deepening of specialist's interdisciplinary knowledge oriented towards problematic situations being solved in scientific, designing and business activity; increase of the level of methodological integrity of cognitive, professional, and communicative activity; provision of natural-scientific and humanitarian knowledge and transition to complex criteria of productivity, effectiveness and quality of activity; ability for widening the scientific bases of social and professional activity at the expense of its methods, generalization and various designing types.

The important components of educational concept in this respect should become learning material and educational technologies, which create the conditions to form innovative mentality: multicriterial problem setting and solving, original thinking, stable skills of informational culture possession etc.

The inevitable element of the concept implies special training on technology transfer, including digestion of knowledge and formation of methods of systems engineering and programming of growth and development, strategic management and business activity marketing, formation of scientific base of technology transfer, mastering the methods of cross-cultural communication.

It is necessary to include the system of knowledge on forming the methods of innovative business activity in the sphere of technique and technology.

The determined methods of reorganization of educational concept should provide the basis for creation and development of innovative education in Russian high school, which presents one of the most important tasks of the doctrine.

Educational professionalization is directed at training the new type of scientific-technical professional specialist, who possesses global thinking, encyclopedic knowledge, and refined mind, able to work creatively at all stages of life circle beginning from research and constructing up to technology development and business activity.

Professionalization in the real educational practice is achieved by the mastering of engineering and engineering culture and practical training (system methodology, conceptual designing and programming of development).

One of the main sides of engineering education should become practical knowledge of foreign languages as the means of cross-cultural communication.

On the threshold of the third millennium creation of the high level of informational culture seems to be an important demand of engineering productivity provision.

Informational intellectual technologies, accumulated informational resources in the form of databases and knowledge, informational logical models, huge computational capability and means of global telecommunications create the basis for the denial from functional division of labor in scientific technical activity and for the first time in the history of mankind provide opportunities for creation of the complex systems in the creative laboratory of a certain person.

The principle of transition to the new educational technologies

The development and creation of alternative technological, social and pedagogical decisions, the usage of ideas and new high technologies providing multiple increase of effectiveness of pedagogical work, the creation mass “production of talents”, the usage of open education are of great importance for the implementation of the engineering education doctrine.

The fact that the system of engineering education becomes the sphere of mastering the methods of cognitive and engineering activity, communicative and engineering culture, cardinally changes the idea of the institute with its teaching and educational process. The most important guideline of the engineering education development in this respect is the special organization of a student’s work during the whole period of studying at the institute in complex multidisciplinary practically oriented groups, the creation of the purposeful forms of education with students actively involving themselves in creative work and participating in research projects. All this should create the premises for step-by-step transition in the engineering education from teaching and educational (memory training) process to the scientific and educational one. The scientific and educational process can be presented as a system of creative workshops of famous scientists, leading engineers, where permanently renewing community of students searching for bachelor’s, master's and engineering degrees forms a creative group, a scientific school where succession is fulfilled in the methodology of cognitive activity, development of the idea of world and the place of a human in it, of the ideals, values, and aims of scientific and engineering work; where traditions of the art of research and engineering activity are reinforced and transferred with the help of the very research process.

Modern educational technologies in the system of engineering education naturally include wide academic mobility.

Nowadays the just criticism is leveled against self-sufficiency of an institute of higher education in any country to train a professional engineer competitive on the world market of intellectual activity. The necessity of broadening the academic mobility of students for the increase of training quality is obvious.

The export of educational service to the foreign countries on the basis of the integrated internal and extra-mural teaching using the technologies of distant learning will contribute to the development of Russian engineering education.

As our practice shows that the professional educational programs of scientific and technical specialists training are in popular demand and meet the international requirements.

The support of the engineering education quality on the socially significant level

It is of vital importance to elaborate in the doctrine the integrated system of engineering education quality support on the socially significant level. The system must contain the following elements:

- a new generation of **state** educational standards and educational standards of university level based on them;
- the **system** of social and state attestation of educational institutions in the area of engineering;
- the **system** and technology of professional educational programs accreditation;
- the **system** of certification of engineering specialists and granting the engineering certificates of various levels;
- the **system** of social and economic stimuli of the professional growth and the increase of the social status of an engineer;
- the **system** of the permanent raising the level of one's skill and post-university engineering training.

Conclusion

In conclusion I would like to point out the necessity of development of engineering education national doctrine as a document entirely reflecting the viewpoints of scientific and technical community, person and state on the future of engineering education in Russia.

The national doctrine of engineering education must be laid as a basis for the Russian Federal program for the development of professional education; legislative acts and governmental decrees should be adjusted with its regulations; professional engineering ethics should be formed in accordance with it.

The national doctrine of engineering education will become a useful and necessary document only in case the mechanisms are created and its permanent conducting, actualization and development in compliance with the changing conditions; factors and new requirements to the engineering activity are provided.

AN INTERACTIVE ENVIRONMENT FOR FUZZY AND SUPERVISORY FUZZY CONTROLLERS DESIGN FOR INDUSTRIAL PROCESS CONTROL

Francisco José Gomes[1], Clayton Guimarães da Mata[2]

Abstract *— The work is related with a graphic environment for designing and tuning of feedback control systems loops, utilizing PID controllers, PID -like - Fuzzy Controllers and Fuzzy Supervisory Gain Scheduling PID controllers. The environment, totally based on GUI techniques, deals with the more common models of systems utilized in control daily practice. The user may select the desired controller structure and, in a interactive process, to follow a step-by-step procedure for getting the desired final configuration. To facilitate the fuzzy controller design, the environment allows, through "click and drag" techniques, the implementation and tuning of the membership functions in the fuzzyfication and defuzzyfication stages. The environment also incorporates a supervisory fuzzy configuration that adapts the PID parameters, according to the information given by the user. The work is directed to the students in a formal graduate course, as well for operators in a technical training in the control and automation area.*

PALAVRAS CHAVE - . Estrutura de controle nebulosa, controlador nebuloso, supervisório nebuloso, PID adaptativo

INTRODUÇÃO

Atualmente, o computador exerce função essencial na área de ensino de engenharia. Esta exigência, justificada pelo avanço tecnológico, leva a uma busca constante por métodos de dinâmicos ensino correlacionados com o aprendizado auxiliado pelo computador. Este artigo apresenta uma ferramenta computacional útil para estudantes e profissional em treinamento na área de controle e automação de processos, com enfoque nos controladores nebulosos.

Os controladores mais difundidos e largamente utilizados na prática industrial são os com estrutura de três modos, Proporcional + Integral + Derivativo [1], mais comumente referidos como controlador PID, devido à sua estrutura simples e desempenho robusto. Sua configuração e sintonia requer o ajuste de três parâmetros: constante do ganho proporcional, constante de tempo integral e constante do ganho derivativo. Ultimamente, grandes esforços têm sido empregados no desenvolvimento de técnicas e procedimentos para sintonia destes parâmetros visando à otimização das dinâmicas em malha fechada de estruturas contendo estes controladores.

Os controladores PID, grosso modo, podem ser divididos em duas classes principais. Na primeira categoria, seus parâmetros de sintonia permanecem fixos, uma vez que tenham sido sintonizados em algum ponto, considerado ótimo segundo algum critério particular adotado. Existem vários métodos para esta sintonia, sendo o mais tradicional e difundido o procedimento de Ziegler-Nichols [2]. Os controladores da segunda categoria possuem estrutura similar ao PID clássico, mas seus parâmetros de sintonia são adaptados "*on-line",* baseados em informações adquiridas da dinâmica do processo sob controle, o que pode requer algum conhecimento preliminar do processo, ou seja, do modelo da planta, a ser controlada. Estes controladores são geralmente denominados *Controladores PID Adaptativos*.

A utilização dos sistemas baseados em experiência, na área de controle de processos industriais, vem crescendo, especialmente no campo do *Controle Nebuloso* [3], [4]. Neste controlador, descrições lingüísticas de experiências humanas, representadas por regras e implicações fornecidas pela lógica nebulosa, formam uma base de conhecimentos usada pelo mecanismo de inferência, que gera uma ação final de controle. Esta ação pode ser baseada, por exemplo, no sinal de erro e em sua derivada (ou diferença) no tempo, expressa pela diferença entre a variável controlada e o sinal de refer6encia.

O ambiente digital desenvolvido, apresentado neste artigo, explora a aplicabilidade e diversidade dos controladores para automação, mais especificamente em modelos de processos mais freqüentes no meio industrial. Para esta análise foram selecionados três concepções distintas de controladores: o controlador nebuloso com estrutura PI, o controlador PID clássico e um controlador PID adaptativo com estrutura supervisória nebulosa [5]. As estruturas desenvolvidas, bem como as telas principais do ambiente, com exemplos de simulações comparativas, são apresentadas na sequência. As conclusões finais encerram o trabalho.

CONSIDERAÇÕES PRELIMINARES

O objetivo pretendido, ao se desenvolver o ambiente do *Controlador de Processos Industriais*, ***CPI***, foi possibilitar um interface entre o graduando de engenharia da área elétrica/automação, com modelos de processos rotineiros e comuns no meio industrial, com as respectivas estruturas de

[1] Francisco José Gomes, Universidade Federal de Juiz de Fora, Rua Benjamin Constant, 790, 36.016-400, Juiz de Fora, MG, Brasil ,chico@jfnet.com.br
[2] Clayton Guimarães da Mata, Universidade Federal de Juiz de Fora, Rua José L. Kelmer, 1018, 36.180-330, Juiz de Fora, MG, Brasil, clayton@pet.ufjf.br

controle, disponibilizando para o mesmo uma importante ferramenta para simulações. As simulações e análises são efetuadas em "tempo real", utilizando as estruturas já mencionadas dos controladores PID clássico, PI nebuloso e supervisórios nebulosos para sintonia PID. O programa foi desenvolvido em linguagem de programação DELPHI [6].

A exigência de se construir um ambiente digital para simulações surgiu como uma resposta frente às necessidade da área de controle do curso de Engenharia Elétrica da Faculdade de Engenharia/UFJF, pois tal ferramenta funcionaria como um passo intermediário entre os estudos conceituais na área de controle e as práticas de laboratórios, facilitando o entendimento e consolidação dos fundamentos teóricos trabalhados nas disciplinas.

Entre as principais características do *CPI*, quando comparado a outros ambientes atualmente existentes, pode-se destacar:

- Geração dos sinal de saída do sistema em "tempo real".
- Possibilidade de mudança de referência, perturbação e parâmetros da planta durante a simulação, com visualização da resposta do sinal de saída em "tempo real".
- Sintonia do controlador PID, PI nebuloso e PID com supervisório nebuloso em um processo interativo simples, de fácil manuseio.
- Alternativa de mudança de velocidade de amostragem para a plotagem do sinal de saída, possibilitando uma melhor visualização de respostas em processos de baixas constantes de tempo.
- Fácil manuseio, com uma interface auto-didática.

ESTRUTURA COM CONTROLADOR PI NEBULOSO

A figura 1, a seguir, mostra a tela de entrada do *CPI*. Nela, o usuário pode escolher um dentre os seis modelos disponíveis, bem como o tipo de controlador aplicado à planta. Serão apresentados, nesta seção, procedimentos para utilização de uma estrutura de controle do tipo PI nebuloso.

A escolha dos modelos é efetuada através dos botões ao lado esquerdo da janela, que, quando acionado, acende um contorno verde e mostra o modelo no painel central à tela. Os desenhos nos botões estão conforme a representação de malhas por Mason [7] [8].

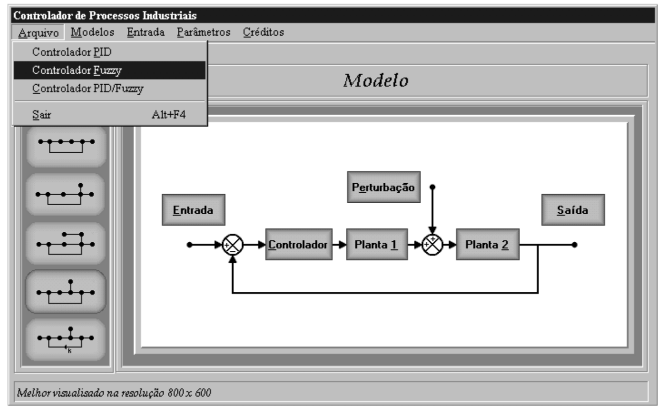

FIGURA. 1
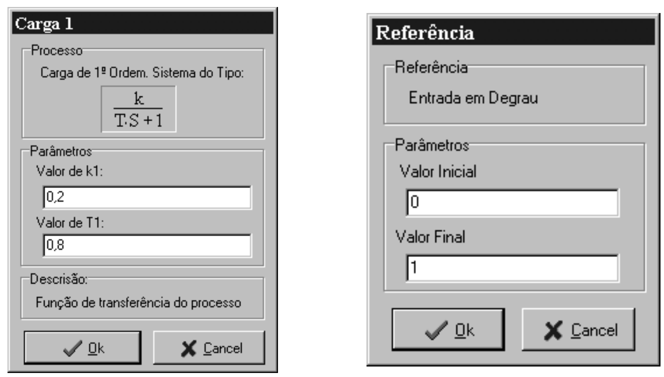
TELA DE APRESENTAÇÃO.

Os valores de entrada do sistema são definidos pressionando-se o botão do mouse sobre os blocos correspondentes. As figuras 2(a) e 2(b) descrevem a inicialização das constantes das plantas e da perturbação em degrau (referência e rejeição de carga) respectivamente:



(a) (b)

FIGURA. 2
JANELAS DE ENTRADA DE DADOS.

A sintonia do controlador PI nebuloso é pré-ajustada pela janela mostrada na figura 3, utilizando-se para isto as funções de pertinência para a nebulização dos dados de entrada para o controlador. Nesta tela, o usuário escolhe o limite máximo positivo (ponto *e*), sendo que os demais limites se ajustam automaticamente. Este ajuste automático torna-se possível pelo fato do controlador utilizar, por opção de projeto, funções de pertinência triangulares simétricas. Esta opção não tira o caráter de generalidade do sistema, haja vista que esta opção é, de forma geral, a mais utilizada nos diversos projetos de controladores nebulosos.

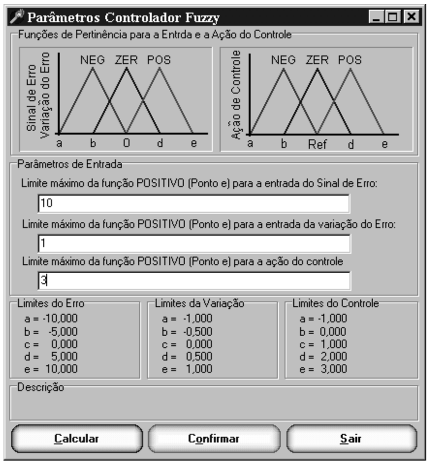


FIGURA. 3
TELA DE SINTONIA PARA O CONTROLADOR PI NEBULOSO.

Com um "*click"* do mouse sobre o botão de saída, começam automaticamente as simulações para o sistema escolhido. Observar que o ambiente disponibiliza, em uma tela única, quatro campos de plotagem que mostram as dinâmicas da variável controlada, da lei de controle, do sinal do erro e da variação deste último no tempo, informações estas últimas utilizadas diretamente pelo controlador.

Na delimitação dos "*Parâmetros"* estão os valores de entradas escolhidos anteriormente e sujeitos a qualquer alteração dinâmica, como ruptura de modelo, mudança de referência, perturbação de carga ou mudança de sintonia do controlador, que serão introduzidas em tempo real ou após um tempo determinado, de acordo com a escolha do usuário (Figura 4).

Observar que, a qualquer momento, o usuário pode efetuar nova alteração dos parâmetros já selecionados, com o ambiente efetuando nova simulação a partir deste momento, funcionando, desta forma, com características de "tempo real".

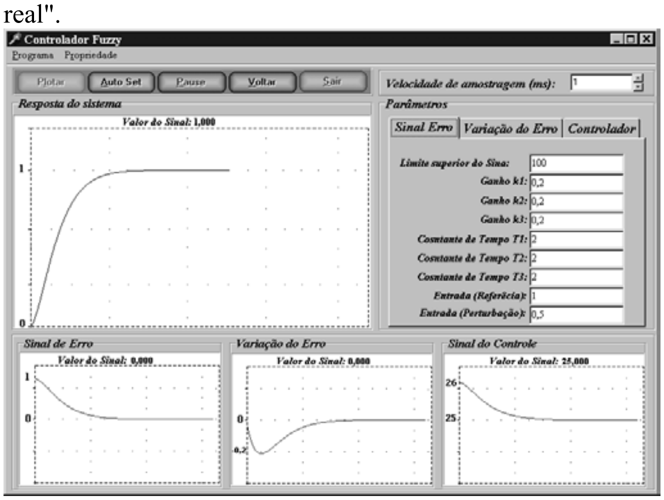

FIGURE. 4
TELA DE SIMULAÇÕES.

ESTRUTURA COM CONTROLADOR PID CLÁSSICO

Para a inclusão do controlador PID clássico à malha de controle, em substituição ao PI Nebuloso, basta efetuar sua seleção no menu *Arquivo* da tela principal, conforme mostra a figura 1. As telas para a entrada dos valores em degrau referência, rejeição e carga e ruptura de modelo são as mesmas descritas em 2 (a) e (b).

A sintonia do controlador PID é pré-ajustada pela janela mostrada figura 5. Nesta, o usuário escolhe os valores das bandas Proporcional, Integral e Derivativo

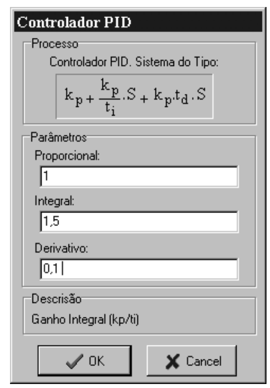

FIGURE. 5
CAIXA DE ENTRADA DOS PARÂMETROS DE SINTONIA DO PID.

A tela de simulação é mostrada na figura 6**.** Nos quatros campos de plotagem estão dispostos os sinais da resposta do sistema ao controlador PID, (podendo atuar ainda como PI ou PD), e a resposta ao P, I e D, atuando isoladamente.

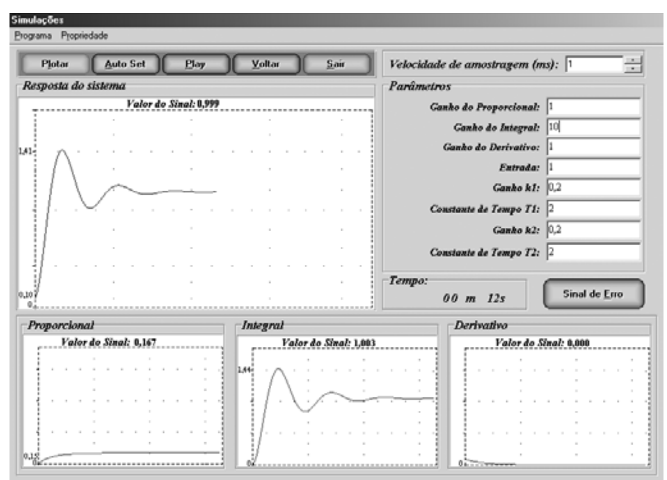

FIGURE. 6
TELA DE SAÍDA DE SIMULAÇÕES.

O *CPI* também oferece a visualização do sinal de erro, como mostrado na figura 7:

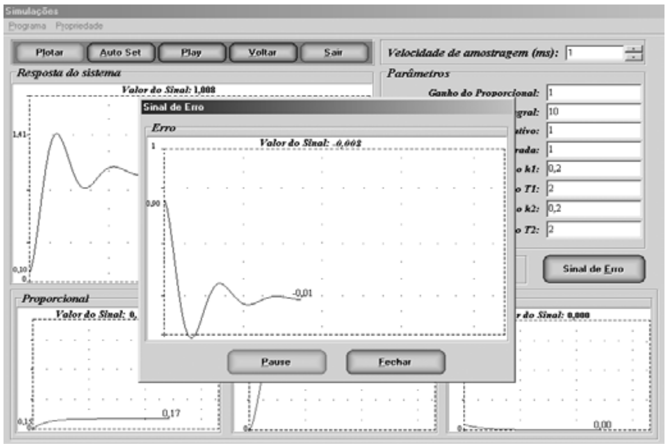

FIGURE. 7
TELA DE SIMULAÇÃO DO SINAL DE ERRO.

Observar que os valores numéricos sobre as curvas são mostrados quando habilitados no menu "*Propriedade – Cursor*", acompanhando a dinâmica das curvas durante todo o processo de simulação.

ESTRUTURA COM O CONTROLADOR SUPERVISÓRIO NEBULOSO

A escolha da estrutura de controle PID com supervisório nebuloso é apresentada na tela inicial do *CPI*, conforme mostrado na figura 1. A escolha é feita através do menu "*Arquivo - Controlador PID/Fuzzy*". Para esta opção de controlador é seguido o padrão de entrada de valores dos anteriores, como para a perturbação de referência, rejeição de carga e para as plantas, sendo estas entradas efetuadas pelas "*janelas*" da figura 2(a) e (b). A tela de simulações é apresentada na figura 6. A sintonia do Controlador supervisório é pré-ajustada pela janela mostrada na figura 8. Nesta, o usuário entra com o valor de k_u e T_u, Ganho Limite da Estabilidade e Período de oscilação limite da estabilidade [2], que estão intimamente relacionadas com o projeto do supervisório utilizado [5].

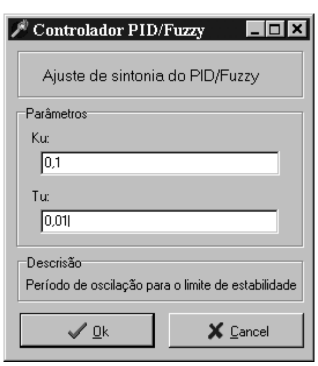

FIGURE. 8
TELA DE SINTONIA DO CONTROLADOR PID/FUZZY.

CONCLUSÃO

O presente trabalho consistiu no desenvolvimento e implementação de estruturas de controle do tipo PID, PI nebuloso e supervisório nebuloso para sintonia PID. As motivações que deram suporte a esta decisão foram:

– Estudar e desenvolver estruturas de controle para processos comuns no meio industrial, com ênfase na estrutura supervisória para sintonia do controlador PID, a qual foi dedicado maior parcela de pesquisas.

– Criar uma um ambiente de simulações em tempo real para estudos de controladores aplicados em plantas industriais, fornecendo uma ferramenta útil para estudantes de engenharia elétrica/automação, podendo ser utilizado como ferramenta didática nas disciplinas de Controle.

O processo de desenvolvimento foi efetuado utilizando os conceitos subjacentes à lógica nebulosa, baseado na proposição de Viot e Zhao-Tomizuka-Isaka [5] na qual foram introduzidas modificações buscando maior eficácia na otimização do processo de controle.

AGRADECIMENTO

Ao Programa Especial de Treinamento – PET/SESu – UFJF.

CONTROL AND AUTOMATION TEACHING: AN UNIFIED APPROACH IN A GUI DIGITAL ENVIRONMENT

Breno Scopinho[1], Clayton G. Mata[2], Francisco J. Gomes[3], João C. Netto[4] and Leonardo A. M. Moraes[5]

Abstract — *The work deals with a graphic environment that allows the user to plan, tune and analyze feedback control systems loops, involving he more common models of systems utilized in control daily practice. These models include PID controllers in the feedback loop and, in all cases, controllers' gains tuning are possible by changing the electronic circuit of a PID structure. The process models are of first and second order, in the s domain, but working also with their associated electronic circuits. All the parameters of the models and controllers can be changed in "real time", allowing the user to analyze their effects on the final dynamics. Besides, the environment includes a "step-by-step" procedure for designing a control system based on the pole placement technique, in the state-space, for an inverted pendulum. The importance of this work is mainly in giving to the student a strong relationship between theoretical models and its physical implementations through electronic circuits, embedded in a friendship environment.*

Index Terms — *Engineering Education, Control and Automation Education, Digital Environment, PID Controllers.*

INTRODUCTION

The computer is becoming an essential tool in teaching and training of projects and analysis of control systems. This fact relays on its capacity to determine the systems dynamics under analysis, in a closed or open loop, to help in the tuning of controllers and analyze its performance, prior to the construction of the physical systems. Through several situations simulated, dynamics with desirable characteristics can be obtained, taking in account parameters like dumping, settling time, stability, overshoots, and others.

In the teaching process of control and automation, however, some difficulties generally arises when trying to conciliate theoretical concepts, like the conceptual analysis of the systems, with their ordinary physical implementations. Excellent simulators, like Simulink, use basically mathematical tools, while practical aspects of implementation of these systems can be analyzed only with others environments like PSpice. The difficulties grow up when the training imposes the necessity of physical modules, that are, in general, imported and with expensive prices.

Analyzing this situation, the present work – a graphical simulation environment – was implemented based on conventional mathematical tools, basically transfer functions and state-space equations, allowing the user to define and tune the parameters of control systems (plants and controllers), verifying the associated dynamics in "real-time". The most important environment characteristic is the fact that the systems – plants and controllers – can be analyzed and worked not only as mathematical functions, but also as electronic circuits, allowing the user to operate with mathematical models and/or physical implementations.

The next section deals with the module based on Proportional-Integral-Derivative (PID) controllers. Its electronic circuit is accessible to the user, allowing its tuning through alteration of capacitors and resistors values. With this environment is possible to have, graphically, answers of, to references changes, load rejection and models rupture, in "real-time". This open the possibility of using the "PID Controller" in a very extensive range of applications, involving academical applications and even industrial operators training.

The following section illustrates the state-space project module. Elaborated as a step-by-step project manual, based on the classical inverted pendulum system, it allows the user to analyze its relative and absolute stability, trough poles placement. The final conclusion ends the work. All the sections, additionally to the conceptual contents of each module, display some environment screenshots and the possibilities they offer to the user.

PID CONTROLLER

This section deals with the PID Controller module, that simulates in closed-loop the most common models utilized in practical control configurations that embraces the majority

of the common industrial area control situations. The selected systems, in their several configurations, are presented in closed-loop, with unitary or first-order dynamic feedback, and with a PID controller.

Models

The developed environment allows the simulation of six classical systems in closed-loop configurations:

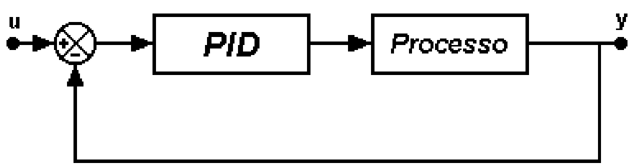

FIGURE. 1
MODEL 1.

Figure 1 shows the first simulation model, with first- or second-order dynamics, according to the user's choice, and unitary feedback.

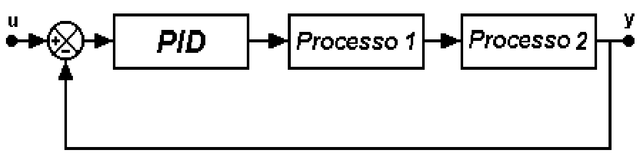

FIGURE. 2
MODEL 2.

The second model, as displayed in Figure 2, consists of two first- or second-order processes, cascade configuration and unitary feedback gain, allowing simulation of third or fourth orders dynamics.

For these two first models is possible to define reference alterations and model rupture. The third option, presented in the Figure 3, has first- or second-order dynamics, unitary feedback gain and allows reference alterations, load rejection and model rupture.

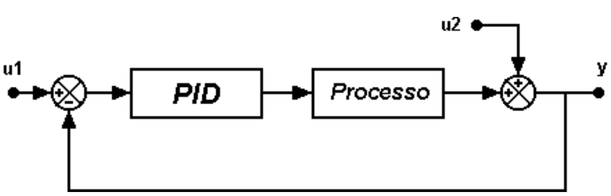

FIGURE. 3
MODEL 3.

The fourth model selected, shown in the Figure 4, simulates dynamics of first- or second-order, unitary feedback gain and allows reference alterations, load rejection and model rupture, in a different configuration.

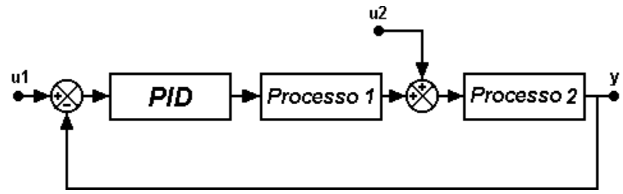

FIGURE. 4
MODEL 4.

The fifth model opens the possibility of selecting the load perturbation dynamics, according to the user's selection.

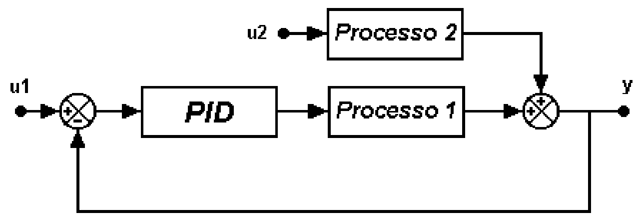

FIGURE. 5
MODEL 5.

The last model, shown in the Figure 6, offers additional characteristics to the fourth model, by including not-unitary feedback gain, selected by the user.

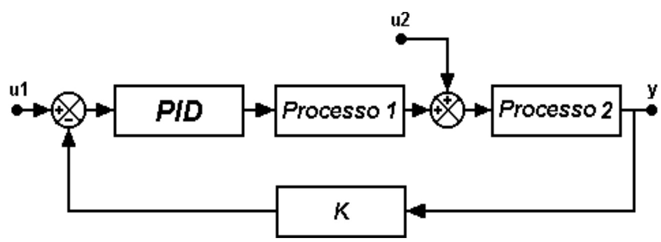

FIGURE. 6
MODEL 6.

All the presented options, like perturbations and alterations introduced in the systems, are selected through a friendly graphical environment.

The Program

The initial screen of the environment allows the user to select the models for simulation, available with its characteristics, just scrolling over the mouse on the icons. Figure 7 shows, as an example, the choice of the first model.

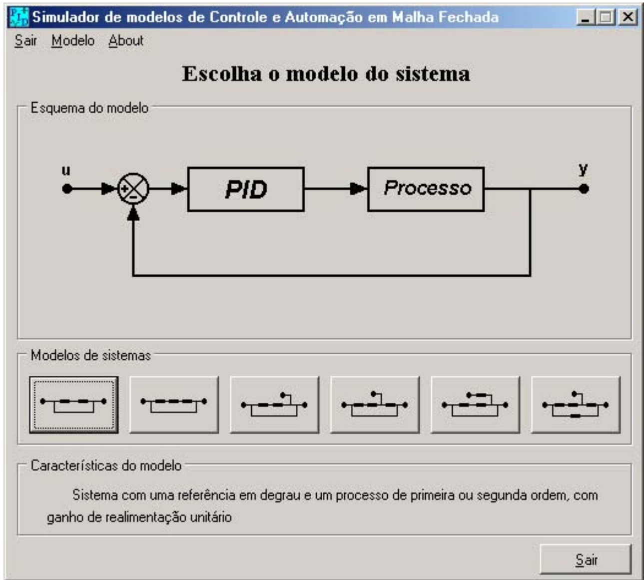

FIGURE. 7
INITIAL SCREEN OF THE PID SIMULATOR.

Figure 8 shows the simulator screen, after selection of the model, "waiting" for the simulation start. The PID controller tuning is possible trough "clicking" on the PID block, on the closed-loop block diagram. In doing so, the window containing the schematics of the analog electronic circuit of the controller is opened, as shown in Figure 9.

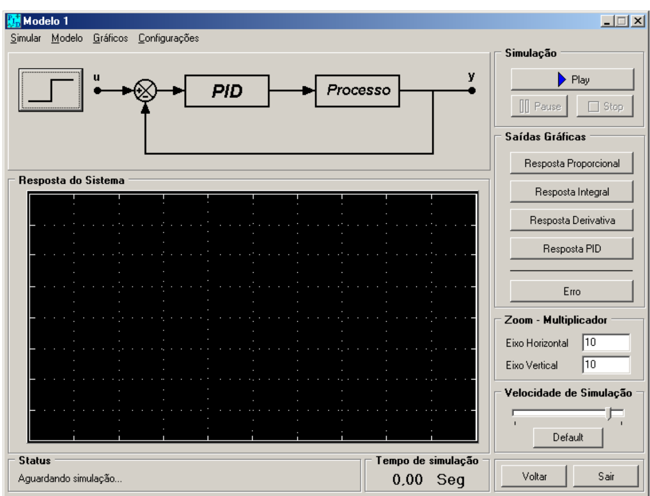

FIGURE. 8
"WAITING" SIMULATION OF THE MODEL 1.

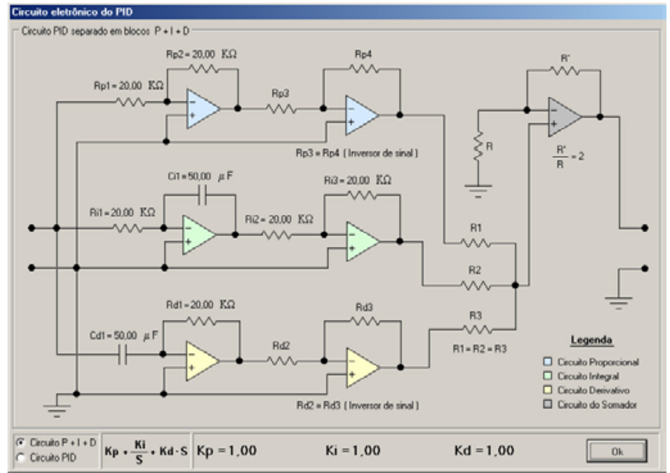

FIGURE. 9
SCREEN OF THE ELECTRONIC CIRCUIT OF THE PID CONTROLLER.

Figure 10 shows the input screens for reference alterations, allowing analysis of the servo behavior, and the plant parameters, which allows model rupture.

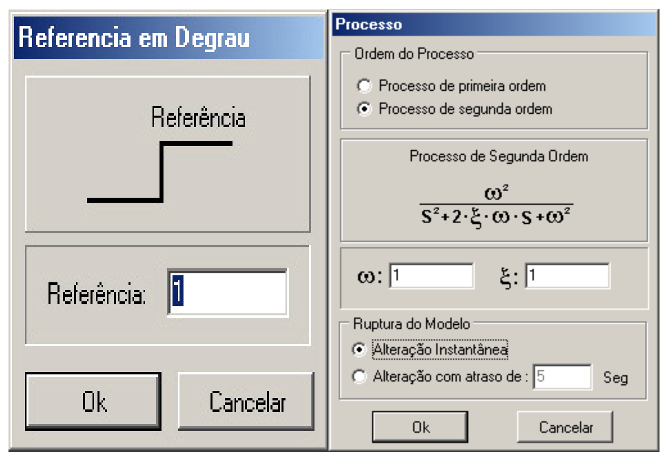

FIGURE. 10
INPUT SCREEN FOR THE REFERENCE AND PROCESS VALUES.

In a similar way, the models can also be analyzed through its electronic circuits, allowing selection of the parameters (gain and time constant) directly in the hardware or through numerical values.

The several systems are modeled by their differential equations and solved with the 4th order Runge-Kutta method.

While the simulations are running, all the values (controller tuning, plant and perturbation constants) can be changed in "real-time". The alterations influences on system dynamics can be analyzed by the user either graphically or numerically. As the environment was designed for teaching and training purposes in the process control area, the following screens are available to the user:

- **Controlled variable**: the user can follow the evolution of the perturbations on the final dynamic of the controlled variable.
- **Separated PID Controller modules actions**: aiming a better user understanding of the PID controller modules, the environment displays, simultaneously, separated windows for the proportional, integral and derivative modes, allowing the user to analyze each one's influence on the final control law.
- **Control Law**: the environment also displays, graphically and numerically, the final control law corresponding to the three PID modes sum, allowing the user to verify its final composing.
- **System Error**: finally, is also showed the deviation between the controlled variable and the reference allowing the user to verify, numerically, the error dynamics for the selected perturbation.

The controlled variable graphical is displayed on the simulated model window and the others ones are shown in separated windows, opened according to the user's need. Figure 11 is an example of the controlled variable graphic, with the proportional answer displayed on a separated window (right).

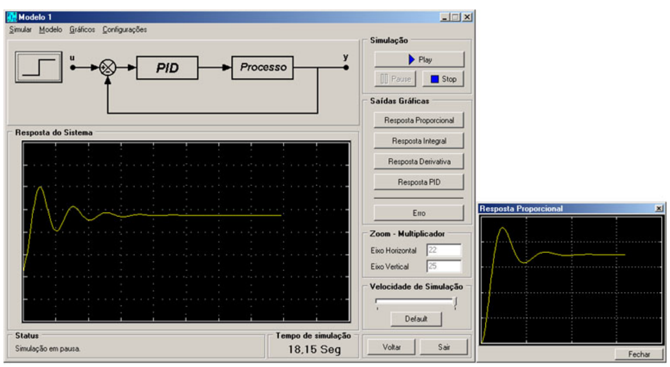

FIGURE. 11
GRAPHICAL OF THE CONTROLLED VARIABLE WITH THE PROPORTIONAL ANSWER IN ANOTHER WINDOW.

INVERTED PENDULUM SIMULATOR

As mentioned, the implemented environment incorporates a case of state variables controller design, based on poles placement methodology applied to a classical control problem: the inverted pendulum. The user has the possibility of implementing, step-by-step, with the help of the simulator, the poles placement controller, checking the system behavior for alterations on its closed-loop poles.

The Inverted Pendulum

The system consists of an inverted pendulum constructed on a cart commanded by a motor, generating a unstable system, falling laterally, at any time, unless an adequate force is applied on the car, driving the pendulum to a vertical position.

The selected model, state-space equations based, can be obtained on the specific bibliography and has the form:

$$\begin{bmatrix}\dot\theta\\ \ddot\theta\\ \dot x\\ \ddot x\end{bmatrix} = \begin{bmatrix}0 & 1 & 0 & 0\\ \frac{M+m}{Ml}g & 0 & 0 & 0\\ 0 & 0 & 0 & 1\\ -\frac{m}{M}g & 0 & 0 & 0\end{bmatrix} \cdot \begin{bmatrix}\theta\\ \dot\theta\\ x\\ \dot x\end{bmatrix} + \begin{bmatrix}0\\ -\frac{1}{Ml}\\ 0\\ \frac{1}{M}\end{bmatrix} u \qquad (1)$$

$$\begin{bmatrix}\theta\\ x\end{bmatrix} = \begin{bmatrix}1 & 0 & 0 & 0\\ 0 & 0 & 1 & 0\end{bmatrix} \cdot \begin{bmatrix}\theta\\ \dot\theta\\ x\\ \dot x\end{bmatrix}$$

The model used in the majority of current applications, and also in the developed environment, is a linearized one. Supposing the angle θ (angle between the bar and the vertical axis) is small, the sin θ can be approximated to θ, cos θ = 1 and $\theta^2 = 0$.

Poles Placement

Mathematically, is possible to prove that if a closed-loop system is completely controlled by the state, then its poles can be put anywhere in the complex plan, using the state feedback, through an appropriated feedback gain matrix. Specifically in this case, the system is completely controllable if its controllability matrix M has a rank equal to 4.

This matrix M for the system of the inverted pendulum is given by:

$$M = \begin{bmatrix}0 & c & 0 & a\cdot c\\ c & 0 & a\cdot c & 0\\ 0 & d & 0 & b\cdot c\\ d & 0 & b\cdot c & 0\end{bmatrix} \qquad (2)$$

where

$$a = \frac{M+m}{Ml}g \qquad b = -\frac{m}{M}g \qquad c = -\frac{1}{Ml} \qquad d = \frac{1}{M} \qquad (3)$$

If the system is completely controllable by the state, a state feedback matrix can be calculated, just like its respective equations.

The Simulator

Considering the inverted pendulum as a system with one input (the force u acting over the cart) and two outputs (the position x and the angle θ between the bar and the vertical axis) and using its model equations, the environment displays its dynamics through graphics or animated frames. Using this option, one can see the sketch of the inverted pendulum moving according to the answer of the system.

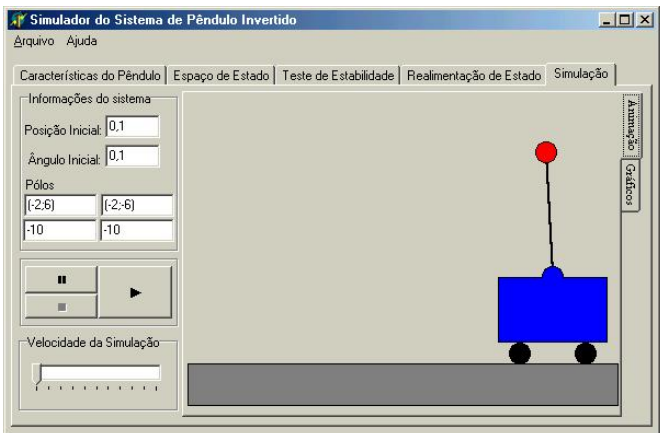

FIGURE. 12
SCREEN OF INVERTED PENDULUM SIMULATION AT ITS INITIAL POSITION.

FIGURE. 13
SIMULATION OF THE INVERTED PENDULUM SYSTEM OCCURRING.

The simulator also offers the option of varying the system parameters (pendulum mass and length and car mass), the initial position and angle and the closed-loop poles, which determine its final dynamics.

Step-by-step, the user analyses what happens during the process of designing the control system. When the simulation starts, the simulator takes on stability tests to verify the possibility of doing the poles placement, indicating to the user, step-by-step, the procedures for getting the final controller design. During this process, it is built the system feedback matrix, asking for the user to determine the closed-loop poles positions. The system then determines the answer corresponding to the variation of the position x and θ. At the end, these variables are exhibited in a graphic form, where parameters like the output of the system, as well factors like accommodation time and dumping factors can be analyzed.

Figure 13 shows the inverted pendulum simulation screen with the characteristics imposed by the user, for the pendulum and the composition of the graphical outputs.

CONCLUSIONS

This work is extremely useful in the study of control and automation procedures due to its user-friendly interface. With a differential characteristic of having mathematical models linked directly to their physical implementation, the environment allows and facilitates the understanding and operationally of the control laws and procedures by the users. Based on common models that can be utilized for representing the dynamics of most industrial processes, this work is very important for academical studies and training of industrial systems operators.

THE ART, SCIENCE, AND PSYCHOLOGY (ASP) OF DEBUGGING

Russell E. McMahon[1],

***Abstract** -- As any computer language teacher knows it doesn't take long before a student produces his/her first bug. Therefore, it is not only important to teach students good programming techniques, but also, how to debug. In a lecture it is important that debugging is addressed early and in a lab situation it is imperative that an instructor can quickly debug a student's program. A student who has no concept of debugging will likely have a difficult time completely homework assignments on time. A student's failure to successfully debug a program can also results in the failure of the concept being adequately learned and a lot of frustration on both the learner's part and the teacher's part. Students need to understand that their own perception of their code is as important as knowing how to code. Ideas on how to conduct lectures, labs, homework, and tests will be given.*

Index Terms -- computer programming, debugging, problem solving, programming

1. Introduction

Ever since Grace Hopper "debugged" the Mark II in the 1940s this term has been an integral part of computer programming. Debugging skills are important and its mastery is necessary for anyone who plans on a career in the Information Technology (IT) field. Debugging is a form of problem solving that has three aspects to it: an art, a science, and a psychology. Grace Hopper popularized the term "debugging" in the computing field on that fateful day in 1945 when Howard Aiken (her boss) asked her what she was doing. Her bug was a real one, a moth to be exact[1].

If you want your students to both enjoy coding and be successful at programming, it is important that they learn how to debug quickly and thus, be able to concentrate on the concept that is currently being taught. Often times, it is not the concept that is the problem, but those "darn bugs." I even put together a bemusing PowerPoint slide show entitled "Bugs come in all shapes and sizes" to try and get students to think about what kinds of bugs they create and how to find them.

In many ways you are a coach preparing your students for that day when they will indeed have to debug a system that a client needs and all eyes are focused on them. This comes only with practice, patience, and a lot of hard work on the teacher's part and the students' part.

2. Types of Bugs

Basically, there are four kinds of programming bugs: syntactic, run-time, logic, and design. The first three need to be taught in detail to beginning programming students. Design bugs come later during a systems analysis and design course.

Syntactic errors are failures to use the correct grammar of your language and are caught immediately by the compiler (or interpreter) or even beforehand by a "background" syntactic checker of many modern Integrated Development Environments (IDEs). They are usually easy to fix and in general present the least amount of problems for students (provided they are paying attention).

Run-time errors can be either syntactic errors not identified by the compiler ahead of time or errors that result in the program crashing. Performing an "illegal" operation like division by zero or moving string data into a numeric field are example of these. The compiler is unable to catch these kinds of errors because the values of the variables are unknown until run-time. These errors cause your program to throw an exception, which a programmer may want to handle programmatically.

Most beginning students spend their time here when it comes to debugging. Part of the problem is that students tend to write too much code before they test it especially, if it compiles clean. Therefore, the instructor should also spend more time teaching how to deal with these kinds of bugs.

Logic errors can be from problems with the design of the application to assumptions being made about what is acceptable output. The algorithm used may be the wrong one or something as simple as not testing for all the possible values of a variable. These kinds of bugs required a good testing plan to be put in place and are the hardest to detect and find. Often times these are created as a result of poor design.

Logic errors can lie dormant for a long time before they are detected and if they are not discovered soon enough, their output becomes they may become the accepted answer. This is why companies need to spend a lot of time testing an application before it goes to production (and retesting it after it goes to production).

Logic errors are hard for many students because they don't take the time to verifying the results. As with the run-time error mentality, if students get a program to run and it looks pretty good then it is OK to turn in for credit. The best

[1] Russell E. McMaon, University of Cincinnati, ML 0103, 2220 Victory Parkway, Cincinnati, Ohio 45206, russ.mcmahon@uc.edu

way to teach this is to give students a completed program and have them develop and implement a testing plan.

Design errors occur at the start of the development cycle and a poorly designed program is doomed to failure. However, this topic is more suited for a systems analysis course, advanced programming techniques course, or software engineering course. A good design does not mean logic errors won't exist. Testing is still a very important aspect of enterprise development. In a beginning programming course, design errors are not as big since most programs written are fairly short. As a student progresses, both testing and good design become a key aspects of the system development life cycle.

3. Research

Recent studies indicate that programmers spend between 50 – 80% of their time on debugging. If these numbers are only half right this would still reflect an enormous amount of time and energy being spent on something that is obviously a major problem with application development[2]-[3]. In a recent study by the National Institute for Standards and Technology (NIST) it was found that software errors cost the US economy roughly $59.9 USD annually. This report estimates that more than half the bugs are not found until well into the development cycle or after the product has been sold or put into production[4].

In his book Code Complete, Steve McConnell points out that the industry average for code production is 8-20 lines of correct code per day. He further points out that there are 15-50 errors per 1000 lines of delivered code. Mr. McConnell recommends that programmers learn how to code more defensively[5]. Since most applications go into the millions lines of code these bugs can become an enormous drain on the programmers supporting them and the companies using them

Marc Eisenstadt of the Open University wrote a paper entitled "My hairiest bug war stories." He collected antidotal information from programmers who related their worse bug nightmares. What is especially interesting is the number of programmers who inherited code from someone else and then were expected to complete the project. Many of these programmers complained that the bugs were there when they got the code.[6]

In a paper entitled "The Debugging Scandal and What to Do About It", Henry Lieberman from MIT states "debugging is still, as it was thirty years ago, largely a matter of trial and error." Part of the problem, Lieberman contents is the "lack of attention to improving the tools for debugging programs."[7] There is also a lack of attention on the instructors' part of teaching students how to use a state-of-the art debugging tool. Debugging is a skill that is not normally taught instead, many students learn it on their own (through "osmosis").

There is currently a lot of excitement about Agile or Extreme Programming with its approach to producing nearly bugless production code. Emphasis is placed on shorter development cycles and lots of ongoing testing and debugging as the system progresses not just after the system is finished[9].

The concepts of debugging and testing need to be taught. Testing is not the same as debugging, but it can show the presence of errors in the code and both skills go hand-in-hand. Knowing one has a bug in his/her program is a start, but it still remains for the programmer to find the bug and correct it. At the beginning level of programming courses, students need to be taught how test and debug their programs and they need to understand that this is an art, a science, and most importantly a frame of mind (psychology) in terms of what one thinks the problem is and how one views their own code.

A special kind of logic error is called the "Heisenbug" name after the Heisenberg Uncertainty Principle. This kind of bug appears in an actual test run of the program, but disappears when run within the debugger. Sometimes it seems to magically appear and then just as quickly disappears. In general, if you don't know what causes, it you have a possible Heisenbug.

4. Art

Debugging is described as a black art or a secret art. It is more of a creative art, which requires the practitioner to use that creative, non-logical part of the brain to track down the bug. The more creative part of our mind is sometimes needed to know where to look for the bug and the willingness to look in the exact opposite place. This form of debugging is where hunches are sometimes the way a programmer finally finds the bug[8].

Debugging will always be an art because of the constant changes in computer languages prevents someone from thoroughly knowing a language. (Many programmers joke that if you know the language intimately, then you are three releases behind.) When switching from one language to a new one there is a new syntax to learn, a new set of compiler rules, a new set of bugs, and sometimes a new paradigm about which to learn (like going from procedure programming to object-oriented programming). All computer languages are different and all have a different set of problems associated with them. Debugging SQL is different from debugging HTML which is different from debugging C# but, it is possible to use all three in the same application.

Debugging is a creative art because even the best programmer knows that sometimes what appears as the obvious location of the bug is really just where it manifests itself and the real bug lays somewhere else. It may even be in the design of the application itself.

Debugging is a learned art. This means learning how to use available tools to see what's going on in your code. This leads to the science of debugging.

5. Science

Debugging is a science. There is a set of rules for general debugging that follows the scientific method. A hypothesis is formed on what the caused the error and is then tested. If the assertion is true then the bug can be fixed quickly and the student is able to move forward with the program. Otherwise, the student must reformulate his/her hypothesis and test again.

There is a methodology that can be applied in tracking down the bug and fixing it. Back in the older days of programming (where punched cards and GOTOs ruled the world) there were no real easy ways to debug programs except to use some sort of "print" method to display the values of the variables you were interested in seeing and doing a lot of desk-checking. Desk-checking is still a good method to use when all else fails as it requires you to "play" computer and really think about what it is your code is doing.

Debugging requires good analytical skills. Students who are good in math and science tend to be good in debugging. Knowing where to start debugging is the challenge. This can, however, be taught and modeled by the teacher. Code isolation and verification is a good technique to use when presented with a large program that does not work. Comment out sections of code until you are able to narrow the bug down to the offending line of code.

Teach program develop through the use of an IDE. They are very rich in tools that make it quicker and easier to debug. Plus, it is very likely that students would be using such a tool on the job. You can set breakpoints, step through your code, watch the values of your variables, and switch over to the assembled code if you need a closer look at what is going on.

Finally, the science of debugging requires students to read the documentation on any errors they receive. The documentation does not always help in explaining what the programmer did wrong but, it can serve as a guide by telling you what areas of your code you should check. If this is the first time a student of mine has seen this particular error, I expect him/her to use the help facility.

6. Psychology

Sometimes you convince yourself that what was written cannot be wrong and therefore, the error is either elsewhere in the code or in the system outside of your code. The error is staring you right in the face, but you refuse to accept it. Hence the saying: "Programmer know thy self and your compiler." Students need to understand that sometimes they will make mistakes and not be able to "see" them because they have convinced themselves that the code in question is correct. Compilers are constantly being updated and sometimes code that compiled cleanly under an older version fails to recompile in the newer one.

There are three basic questions all coders should ask themselves when they encounter a bug. What sort of errors have I made in the past? What kinds of habits have I picked up that lead to this bug? How can I change these habits? Sometimes the only difference between my students and myself is that I know what kinds of errors I can make and the habits that lead up to this error and they don't.

Students need to understand the psychology of debugging because the mind can be the roadblock in the way of successfully finishing an assigned program in a timely manner or frustrating oneself for hours on end. Getting students to catch their errors sooner instead of later is important. Most of my students agree that some of the errors they have made are because they convinced themselves that the line of code in question or algorithm is correct and therefore the bug must be somewhere else in the code or that the OS, network, IDE, compiler, or some other fluke of nature is the cause of their problem.

One needs to adjust his/her mindset when debugging. First and foremost all programmers need to accept that they will create bugs. This sounds simple enough, but many people have trouble with this. Second, one must feel comfortable enough in his/her programming skills such that bugs can and will be found and appropriately handled. Instilling confidence in your students is very important. They must feel that the bugs they encounter are not insurmountable and that with a little more persistence and work they will solve the problem. Students can become so convinced that something else was the cause of the error that even when it was shown, they still wanted to defend their invalid code. (This has happened to me a number of times.)

Remember what's in the book is not always correct. Most programming books are one release behind the actual product and often times the sample code has not been thoroughly tested. What may have worked before may not work with a newer release of the product. Teach your students to treat all information with caution. This is difficult for beginning programming students because they expect the author and instructor to be infallible experts and they really have no way of knowing what is correct or incorrect.

Another problem is switching to new version of a language or to a whole new language (such as going from Visual Basic 6 to Visual Basic.NET). Although the same errors like dividing by zero will generate an error, the error messages do change (sometimes for the better). (In C# it is possible to execute unchecked code that would normally cause an overflow error. This does not stop the code from executing or from returning results back.)

7. Lecture

In a lecture it is important that good coding techniques be taught. Code that is well designed, written, and structured is less prone to bugs to begin with and is easier to debug later. Students learn early on that I will not help them with a programming problem if their code does not follow good coding standards. Debugging is addressed early in my programming courses with students being introduced to the more common errors of the language they are learning.

Introduce bugs in small doses and give students the opportunity to create their own bugs so they become familiar with the error messages and what they really mean. Teach students to fix bugs before continuing and to test their code every step of the way. Good programming habits will carry a student far. This includes showing them how to use the available help facilities.

Start with an explanation on debugging by asking students if they all know what ASSUME means. Most know what is meant here (don't make an ASS out of yoU and ME). Next tell your students to stop making preconceived ideas about what the caused the error. Many times it is this notion that the error can't be where it appears that causes them problems.

Teach students how to write stub program code and then how to enhance the various stubs as they go alone checking each step before proceeding to the next. Have students identify the important parts of the program and start out small. Teach student how to desk-check. Although, this is not as necessary as in the past, it still is useful and teaches the students how to "think like a computer."

Writing clean code is not so much a problem when students have plenty of time to design/write/test/debug their code as much as it is during a test. Many students believe that writing pseudo-code on a test is better than nothing at all. By pseudo-code I mean the program did not compile, but instead of fixing the problem (because the student could not do so) the student continues to write code pass the problem area. (Damn the torpedoes, full speed ahead) In some cases students do not even compile their code until they are all done with the problem. These habits can be hard to break, but if the rule of "no compile -- no points" is applied, it tends to stop most students from handing in incomplete code.

Although an IDE usually has a debugger built in it and will help a student find the errors, this does no good if the student fails to understand how the program is functioning in the first place. This goes back to the psychology of debugging. The data given back by a debugger is interpreted by a student who may not really understand what the true meaning of the information returned. It is critical that students learn how to decipher the meaning correctly or else they could easily spend more time than needed to solve the problem.

Before sophisticated IDEs and debuggers the standard way of checking what a piece of code does was to insert "print" statements into the code and watch the values as the program ran. Nowadays you can insert a breakpoint in your code and a variable "watch" window will show the variables you are interested in.

8. Lab

Most of our computer-related courses have an associated lab. We feel that a lab is vital to our students' success. Students need practice debugging under a control environment. They need to be shown how programming is done in lecture and practice it in lab. This is the time where I assess a student's ability level. A student who is not very successful in lab is likely to have a hard time with any homework and subsequent tests.

Just as thought of eating an insect makes most people squirm. I like to give my students a set of programs with bugs and watch them "squirm." I have built up a library of "interesting" code for use in my labs. I give them a document with code on it and they have to find the bugs first via desk-checking and later verify their results on the computer. Other times I have students work as teams and create bugs in a program and then have another team debug it. A little competition goes a long way.

I also like to have another student to debug someone else's code. This helps both students. Many times I have seen my errors as soon as a colleague of mine came to my cubicle to help me debug. If those two students can't solve the problem, I may assign a third or fourth student to the bug before I get involved.

During lab time I walk around observing students' work on the computer. Occasionally, I observe a bug that a student has created. However, I do not immediately rush to aid the student instead, I choose to let him/her find it and fix it. If that student later needs my help, I am often times able to look like a magician for the speed in which I found their bug. Of course, this doesn't happen like this all the time so my students know I am fallible.

A programming course without a formal lab makes teaching a language difficult but, not impossible. Treat your labs like a typical science lab. This is the time for students to learn, interact with one another, and discover new things. Students are expected to be there and do the work assigned during that time period. Also, use the lab time to work with individual students. At the University of Cincinnati, we use Blackboard as a means in which students can communicate with their classmates and post their answers.

At the College of Applied Science we have a Programming Learning Center (PLC) where students can go for additional help. This program was started in January 2002 and has a goal of allowing our more advanced students to work with our any of our students who are having problems. Our PLC techs are paid so there is an incentive for them to delve into the problems given to them. The PLC techs can be link with a struggling student for more one-on-one help.

In a lab situation it is imperative that an instructor can quickly debug a student's program. In a beginning course a student can become too frustrated and is then unable to move forward. Even in an advanced programming course it is important that the instructor can debug the program or at least point the student in the right direction. Failure to do this can result in the failure of the concept being adequately learned and a lot of frustration on the student's part.

9. Homework

A professor has less control in this situation so it becomes even more imperative that students learn how to design, write, debug, and test their code. A student hitting a roadblock here can be bogged down for a long time and frustration sets in sooner or later. Keep the list of programming assignments reasonable and add one or two that are very easy to write. Spend time going over possible solutions and buggy solutions.

There are students who are very good programmers and some who can hack their way through most any problem you give them. By in large however, most students are not natural born programmers and need a good foundation before they can successfully build large applications. Both homework and labs are the perfect time for students to practice what they have learned.

Homework should also give the students the opportunity to learn something new about the capabilities of the language they are using. C# for example has extension date/time functions, sort capability, data structures and other functionality already built-into its extensive class libraries. Give assignments that will allow students to learn more about these and expand beyond what you teach or what is in the book.

10. Testing

I generally give three tests a quarter (10-week, 3-quarter system). The first two have a debugging part to it. I test less on debugging as the quarter progresses, but students realize they are responsible for being able to debug their programs. You may need to occasionally help a student debug his/her program during a test. Do this when the bug is something that may not have encountered before or is too obscure to let it impede a student's progress. When you assist a student, speak loud enough so other students are made aware of this problem and can adjust accordingly.

11. Conclusion

There are plenty of articles and books on debugging in a particular computer language and these make excellent resources for learning language specific debugging techniques. Debugging is a form of problem-solving. I enjoy debugging and always have learned something new when presented by what sometimes looks like the simplest bug and it's this life-long learning, that I want to impart to my students.

Teach students how to limit their bugs by testing as they go along. Do not reward students for coding additional code beyond the initial bug. Give students programs with bugs for lab and homework. Not only discuss debugging and how it can be best achieved, but also discuss the psychology of debugging. Students will miss bugs because they are convinced that the area in question was correct and therefore the bug has to exist elsewhere. Be patience with your students. Once they become successful at debugging many of the advance programming concepts become easier to teach because students are now able to concentrate on them and they no longer have to worry about the incidental bug.

CAMPFIRES NOT REQUIRED

Diana K Stewart[1], Clark A. Cory[2] and Mark W. Bannatyne[3]

Abstract — *The question parents have asked over the last couple of decades is "Where can I send the children during the summer?" Summer camps bring thoughts of sitting around a campfire in the great outdoors hundreds of miles away from civilization, but some campers and parents are seeking alternative summer experiences. During the last five summers, the Computer Graphics Technology faculty at Purdue University has hosted a Computer Graphics Camp for high school students. Approximately 100 students travel each year from around the United States to West Lafayette, Indiana, for a weeklong stay on the campus of Purdue University. Throughout the week the students explore a variety of computer graphics software in the laboratories, take tours of companies that produce or use graphic works, and participate in some fun and educational activities in the evenings. This paper will discuss the goals of the camp, the weekly schedule and most importantly, some of the trials and tribulations that occur when working with high school students.*

Index Terms — *Computer Graphics, High School Students, Summer Camp, Technology.*

INTRODUCTION

The Purdue University - Computer Graphics Technology Department prepares visually oriented students who are interested in creating and managing the production of computer graphics for a wide range of industry. Students enrolled in the Computer Graphics program can select from the following disciplines: Construction Graphics Communication, Interactive Multimedia development, Computer-Aided Design, or Computer Animation. The department consists of nineteen faculty members at West Lafayette, the main campus, and five more faculty at the Purdue Statewide Technology Programs throughout the state (see Figure 1). There are approximately 500 undergraduate students enrolled at West Lafayette, 45 graduate students, and 175 undergraduates in the statewide system. The Department of Computer Graphics strives to prepare students to be the nation's best practitioners, managers and leaders of applied computer graphics. The department is also recognized as a national leader through its diverse faculty, staff, and students, and its excellence in learning, discovery and engagement.

FIGURE. 1
PURDUE UNIVERSITY, WEST LAFAYETTE (CIRCLED) AND THE STATEWIDE TECHNOLOGY PROGRAMS.

One of the activities that the department engages in is a Computer Graphics Summer Camp for high school age students. This camp provides students with hands-on sessions in fields such as Computer Animation, 3D Solid and Surface Modeling, Web Development, Digital Publishing, Computer Game Development, Technical Illustration, Engineering Graphics and many other aspects of computer graphics.

COMPUTER GRAPHICS SUMMER CAMP

The question parents have asked over the last couple of decades is "Where can I send the children during the summer?" Summer camps bring thoughts of sitting around a campfire in the great outdoors hundreds of miles away from civilization, but some campers and parents are seeking alternative summer experiences. During the last five summers, the Computer Graphics Technology faculty at Purdue University has hosted a Computer Graphics Camp for high school students. Approximately 100 students travel each year from around the United States to West Lafayette, Indiana for a weeklong stay on the campus of Purdue University.

The goal of the camp is to attract students who are interested in Computer Graphics and expose them to the Computer Graphics Department at Purdue University. During the week, the students are introduced in a stress-free,

non-competitive environment to software such as Photoshop, FreeHand, Flash, Rhinoceros, 3D Studio MAX, as well as a variety of other tools. Finally, the students are challenged in each classroom to create projects that are outlined either by their instructor or themselves.

The Computer Graphics Camp is geared towards high school sophomores or juniors, but freshman and seniors have attended. High school students should be thinking about future career options that will be available upon graduation. What better way to get the students interested in their future than to jump start their professional education with a general introduction to all areas of computer graphics?

The general demographics of the students are extremely diverse. Most are based in the United States with the majority coming from Indiana and its neighboring states, Kentucky, Ohio, Michigan and Illinois. (See FIGURE 2) There have been several students from as far away as Hawaii, Puerto Rico and Alaska. There were even a couple of French foreign exchange students from a high school in Chicago. From north to south and east to west, the students bring to Purdue their diverse background knowledge of graphics.

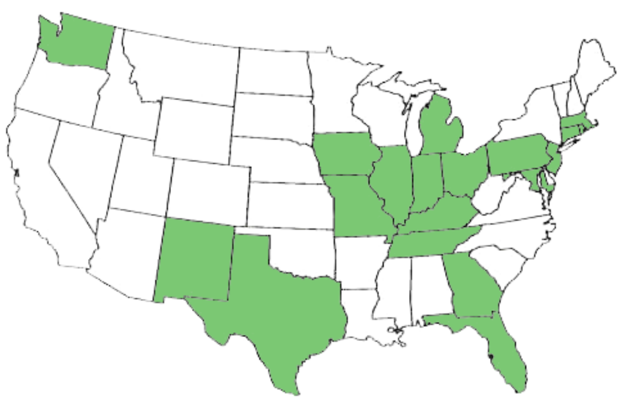

FIGURE. 2
STATES IN WHICH STUDENTS HAVE PARTICIPATED IN THE CAMP.

SCHEDULE

The camp, which is scheduled for mid June, runs from Sunday to the following Friday. The students are divided into groups of twenty-two, the number of computers in the Purdue computer lab. There are either four or five groups in a typical summer camp. Each group has two graphics session a day lasting three hours with a noon lunch break and an evening activity. (See FIGURE 3) The designated lunch break gives the student time to eat and either explore campus or go back into the computer lab for some independent work time. After supper, the group is walked to an evening activity.

Monday, June 17, 2002		**White Team**
7:00 am	Walk-up Call	
7:30-8:00 am	Breakfast	
9:00-Noon	Session 1	FreeHand
Noon-1:30 pm	Lunch	
1:30 pm-4:45 pm	Session 2	T-Shirt Design
5:00 pm-6:00 pm	Dinner	
6:30 pm-9:30 pm	Evening Activity	Physics Show & Campus Tour

FIGURE. 3
OVERVIEW OF ACTIVITIES FOR ONE TEAM

During the week at camp, students participate in computer sessions in the morning and afternoon, rotating through a series of seven computer graphics topics:

1. Vector Graphics – Software utlized: FreeHand
2. Raster Graphics – Software utlized: Photoshop
3. 3D Modeling – Software utlized: Rhinoceros
4. Aniamtion – Software utlized: 3D Studio MAX
5. World Wide Web – Introduced to HTML coding
6. Animation for the Web – Software utlized: Flash
7. T-Shirt Design

Each session takes place in a computer laboratory setting with all the necessary software and hardware to complete projects presented by their instructor. All of the students are provided with disks, binders, copies of projects, and other miscellaneous items that are needed in the classroom.

The seven areas give the students a general introduction to various areas of computer graphics. This curriculum design works effectively with most students, although some demonstrate less enthusiasm about the multiple areas. Some students come to the summer camp with the simple goal of concentrating on one component of computer graphics, and that goal is usually the expansion of their knowledge of animation. It seems that most students attend the camp for a general introduction to computer graphics, but a few just want to expand their knowledge of specific software products. Based on the student evaluations the animation, web, and 3D modeling sessions were selected as the favorites this year.

The following is a sample graphics session in the 3D Modeling. The instructor introduces a software package called Rhinoceros (Rhino). Rhino is a 3-D NURBS modeling program for Windows that is extremely easy to learn and use (www.rhino3d.com). First on the agenda is to introduce the interface and the transformation tools. A file containing a few primitives is given to the students. Using this file the students are asked to move, copy, rotate, and scale the objects. This task allows them to become acclimated to an interface containing a top, front, side and perspective view of the objects in the scene. After a quick introduction to the interface and the transformation tools, the students start working with solid geometric figures like spheres, cubes and cones. They are encouraged to use the primitives to create a rough shape of simple objects like castles, trains, robots, and spaceships. Once they become comfortable with the interface, transformations and primitives, they are introduced to Spline based modeling using revolve and extrude to create 3D geometry. The students are then asked to construct objects such as goblets and decorative vases. The final task of the session is to create some type of building, toy, or character using some of the modeling methods introduced. (See Figure 4)

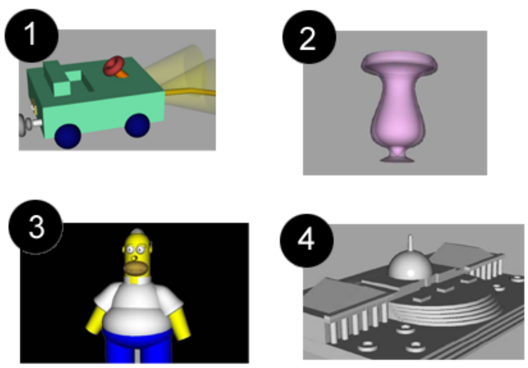

FIGURE. 4
3D MODELSCREATED BY THE STUDENTS IN THE 3D MODELING SESSION.
1. TOY CAR CREATED WITH PRIMITIVES
2. VASE CREATED WITH SPLINES
3. HOMER SIMPSON CHARACTER CREATED WITH PRIMITIVES
4. STATE HOUSE CREATED WITH PRIMITIVES

In addition to the classroom sessions the campers enjoy recreational activites in the evening. Some of the activities that the students take part in or attend are listed below:

1. Purdue Campus Tour
2. Animation Festival
3. Chemistry and Physics Show
4. Swimming Party
5. Billiards and Bowling

The Chemistry and Physics Departments entertain the students with explosive shows highlighting some of the Laws of Chemistry and Physics. Purdue also has many recreational areas including their Olympic Swimming Facility and a Billards and Bowling Hall in which the students can relax and socialize with their fellow-campers. In fact, the billards and bowling evening activity ranked on the student survey as one of the favorites during the camp. The bowling and swimming allow them to release some of the constrained energy. The movie allows them to see computer animations created by past and present Computer Graphics Technology students and animators from around the world. It also gives the students an insight as to what they might accomplish.

One day during the week the campers are taken on a day-trip to Indianapolis, Indiana or Chicago, Illinois to tour industrial and business sites specializing in computer graphics. On these tours the students see first hand the cutting edge of computer graphics and the technology associated with it. The last couple of years the students have toured the Indianapolis Children's Museum which houses the IMAX movie theater. The staff at the Children's Museum also gives the students a tour of their in-house sign shop where all of the exhibit graphics are taken from concept to reality. From there the students visit the Indianapolis 500 Speedway Museum so they can view technology at its best. Finally the day is ended with a visit to the Holcomb Observatory in order to see the stars and the universe. The organizers of the camp have packed this day with tours of sensational places in addition to introducing the campers to businesses that use computer graphics.

Finally, the week is wrapped up with an Awards Banquet that the students' parents, friends, and family are invited to attend. After dinner the camp staff shows a slide presentation of photos that were taken throughout the week to give the attendees a chance to see activites in which the campers participated. Each student that successfully completes the week at camp receives a certificate of completion and is entered into a drawing for free computer related items ranging from mouse pads to printers.

ROLL CALL & CAMP GUIDELINES

Keeping track of 100 campers is not an easy task. All students must attend each and every session and activity at the camp. In order to ensure that all campers are in attendance, roll call is taken in the morning after breakfast, at each computer graphics work session, after dinner before the evening activity, and then once again before the students are dismissed to their floors for the night. Although the students are responsible for getting to every activity, for security reasons roll call is done in every class. If a student does not report for roll call and is not located immediately, the Purdue Police Department is notified that a camper is missing. At this time a search team is sent out to find the missing camper. Once the camper is found the student is dismissed from the camp and their parents are called and asked to make the appropriate travel arrangements for the student to return back home. It is the camp organizers' responsibility to safeguard the students for the week, and they take that responsibility very seriously.

During the five years that the camp has been offered at Purdue there have been very few discipline problems. The first night of the camp the Director reviews the rules and safety regulations for the camp. The main rules are:

1. All campers must attend each and every session at the camp. In an effort to ensure that any camper who does not report to an event is safe, the Purdue

Police Department will be notified immediately it is discovered that the camper is missing.
2. Smoking is not allowed in any building on the campus or at any camp events.
3. Alcohol and illegal drugs in any form are prohibited on the Purdue campus. Violations must, by university bylaw, be reported to the Purdue Police Department.
4. Misconduct toward another member of the camp, or a faculty member, (such as physical or verbal abuse) will not be tolerated. Violators will be excused immediately from the camp for the remainder of the week.
5. Campers who are discovered to be in restricted areas of the dorm or other areas designated as "Off Limits" by university officials and/or camp faculty members will be dismissed immediately from the camp.

After the rules of the camp are reviewed with the students, there is no hesitation by the couselors to take appropriate action if a dicipline problem arises.

RAMPING UP FOR THE CAMP

The coordinators of the camp start preparing about nine months in advance. The camp is advertised in a number of different venues. A letter of invitation is sent to every High School Counselor in Indiana, Ohio, Illinois, Michigan, and Tennessee. An advertisement is also placed on the Computer Graphics Technology website. The other means of advertisement is by word of mouth. Most professors pass along the word at every conference they attend; so the camp is broadcast fairly well. Applications go out to high school counselors in January and are accepted to within two weeks of the start of camp. During this time, other planning occurs.

The planning for the camp is as complex as any conference function. There are scheduled meetings with organizers of food preparation, housing, swimming, bus transportation, field trip organization, and evening activities administrators. Each administrator must adhere to the guidelines Purdue has set for them, and the Computer Graphics Campers must follow those rules. The planning takes approximately two hours per day starting in January right up to the start of the camp.

The camp requires a large commitment from the Computer Graphics faculty and staff. Each graphics session must obviously have an instructor that knows the software and technology that is being introduced as well as chaperones for the evening activities and the day trip. The dormitories at Purdue are staffed with counselors, but the camp is also required to have supervision in the dorms for the campers at night. There are also the little things that can require extra help; for example, most days sack lunches are provided outside of the technology building instead of requiring the students to walk back to the dining room at the dormitory. Having someone who is willing to drive to pick up and deliver the lunches saves quite a bit of time. The organizers of the camp have also recruited undergraduate and graduate students who are attending summer classes or that are on campus for the summer to help out when extra supervision is required.

ASSESSMENT

The last two years of the camp the coordinators decided that the students should have an opportunity to voice their opinions about the camp and the activities in which they participated. The students were asked during the Friday morning's final graphics session to fill out a survey of approximately twenty questions. The questions basically cover the living facilities and dining services, the graphics sessions, the evening activities and the day trip. Each student was asked to rank these areas on a scale from one to ten – ten being excellent and above expectations. A few short answer questions were included at the end of the survey:

1. What other subjects or software would you like to see taught at the camp?
2. What was your favorite activity?
3. If you could change one thing at the camp, it would be...

Other comments were also included by the students on the back of the evaluation sheet. This past year 82 of the 90 campers returned their evaluations. The campers ranked the camp slightly above average on all aspects that were surveyed. In 2001 the results were similar – all slightly above average. The coordinators agree that the camp is meeting the expectations of the students.

Based on the student's comments, there are some areas that could be considered when developing next year's lab sessions. Some students would like to see an introduction to computer programming. Others would like a session on graphic freeware, for example GIMP, which can be downloaded from the internet. This would give them a chance to use graphics software at home without spending the high dollar value for the software that we use in the laboratory. One of the other comments that was included in the written section concerned the amount of roll calls – the coordinators agree that there is no way that the number of roll calls can be decreased. Basically the students want their freedom, but some control must be kept by the adults and supervisors of the camp.

CONCLUSION

The Purdue University Computer Graphics Department has taken the initative to introduce computer graphic to high school students in a structured but stimulating atmosphere. The mix of education, evening activities, social interaction, and promotion of computer graphics works extemely well in capturing the minds of this age group. During the week the campers do not get bored with one aspect of the schedule because there is a variety of technologies to learn. The summer camp gives everyone a chance, instructors included, to learn and grow from the experience. Some of the students come to the camp with refined skills in a particular graphics area, but they quickly discover a lack of general overall graphics knowledge. The camps diverse opportunities allow the students a flexible learning environment to develop additional innovative graphic skills. The camp organizers know that most parents are concerned about their children's welfare, education and future success. It is logical that they should select a summer activity that promotes social interaction and an interest in higher education.

DISTANCE LEARNING OF CAMAC HARDWARE

Sergey E. Gavrilov [1], Sergey A. Kiprushkin [2], Sergey Yu. Kurskov [3], Eugene D. Zhiganov [4]

Abstract *— The idea of extending client-server technology to the types of services other than manipulating various files on a storage media and transferring files over a network is discussed. Special purpose protocol (CAMAC protocol) and server program (CAMAC server) are described and the possibilities of using the server in multi-user training systems are illustrated. Also, different approaches to teaching CAMAC programming are compared with each other. Description of usage CAMAC server in remote training system for organizing laboratory studies on various topics, including, for example, 'Studying CAMAC modules' and 'Remote control of data acquisition system' is presented as an example of our approach. According to this approach students use CAMAC server in conjunction with client programs, which are appeared to be helpful in acquiring basic skills in CAMAC hardware programming.*

Index Terms — CAMAC hardware, client-server technology, distance education, teaching system.

INTRODUCTION

Client-server technology is widely used for building various software systems nowadays. This technology is based on the idea of dividing data processing task between a server program and a client program or programs. Client programs and server program can run on different machines, connected either through local or global network, such as Internet. The role of a server is to provide clients with the possibility to use some resource of arbitrary nature in accordance with the set of rules comprising protocol, whereas clients, using this resource by means of requests to server, perform their specific tasks. Usually, resources are of 'file' nature: file system in FTP, HTML and other files in HTTP, mail messages in SMTP and POP3, data base files in SQL, etc.

Obviously, it is easy to provide clients with resources of some other nature by developing special protocols and writing special server programs.

A number of software systems designed within the client-server model exist, in which the resource supplied to clients has the nature other than files on discs or another storage media. As examples one can mention well known X Window system, which is de-facto standard for graphical output in Unix-like operating systems (resource is graphical display), various remote administration tools for Windows family operating systems (resource is entire machine and tasks run on it), an assortment of print servers in various operating systems (resource is remote printer or printers). Finally, we would like to mention MIDAS data acquisition system [1], designed in Paul Scherrer Institute (Switzerland), which provides for remote access to event-based experiments in nuclear and particle physics (resource are data taken from data acquisition hardware and also the experiment data base).

Particularly, we are interested in extending client-server paradigm to such sorts of resources as experimental setups or data acquisition equipment. We believe that this approach not only allows organizing effective experiment management but also may give the possibility to work several remote users with different constituents of experimental setup simultaneously. The last property can be used for establishing a multi-user remote training system on the base of such setup.

Although MIDAS system contains a part similar to CAMAC server described in this work, we considered it not quite relevant for our goals, since MIDAS itself is designed for use in nuclear and particle physics experiments; the CAMAC server part is deeply integrated into MIDAS and there was no need to use the entire MIDAS for us. Besides, we used to some extent different approach when implementing CAMAC server: namely, we designed our CAMAC protocol directly over the top of TCP/IP protocol family, whereas MIDAS designers used built-in HTTP protocol combined with the remote procedure call (RPC) mechanism.

CAMAC SERVER AND CLIENTS

We used the idea above when implementing special-purpose server program (CAMAC server), which operates in TCP/IP networks and allows remote users to access CAMAC crates. CAMAC is a program-control system of modular electronics created for communication of measuring devices with digital equipment of data processing. We also have developed corresponding application level protocol (CAMAC protocol) and several client programs demonstrating the possibilities of our approach.

This work was supported by Russian Foundation of Basic Research (grant No. 02-07-97503), U.S. Civilian Research and Development Foundation for the Independent States of the Former Soviet Union (CRDF) (award No. PZ-013-02) and Ministry of Education of Russian Federation.

The remote access to experimental equipment in the scheme we used can be described as follows: dedicated computer running Linux operating system is used to control experimental setup which is connected to this computer through CAMAC crate (Figure 1). CAMAC server running on this computer is responsible for providing remote access to CAMAC crates for several clients concurrently. The sequence of operations to be performed over crates (experiment management) is determined by clients. Clients issue commands to server, which performs the operations requested and returns data obtained from crates as well as the information about CAMAC dataway state (for example, the presence of the X-reply from some slot) to the clients.

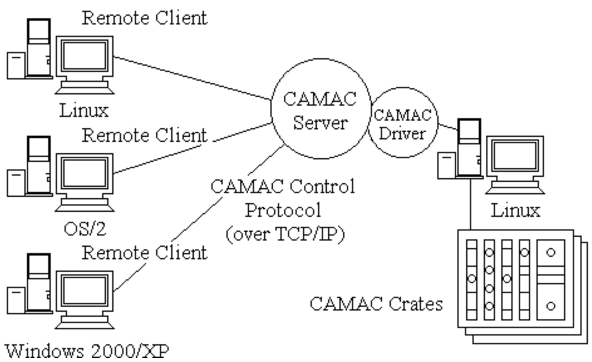

FIGURE 1
CLIENT-SERVER ARCHITECTURE.

CAMAC server is implemented for the Linux operating system in C programming language with the use of TCP sockets technology and is based on the CAMAC protocol developed with the purpose to provide a way for server and client to speak with each other [2]. According to this protocol server is a passive part of the system and the clients are active (client-driven scheme). After client establishes a connection, server sends a textual 'greeting' string, which can be used by the client for the purpose of server identification. Further the data exchange in query-answer mode between the client and the server occurs. Both query from client to server and answer from server to client are six bytes long. The former contains crate number, slot number, address within a module, command code and three bytes of data. Reply from the server includes contents of the control and status register of crate controller, error code and data. Among the commands available in the protocol one can mention 'capture slot', 'release slot' and 'execute standard CAMAC operation' commands.

Typical CAMAC session looks like this: client establishes connection with the server, captures a set of slots needed for it's work, performs data acquisition and then closes the connection. Slot capturing and releasing can occur at any moment of the session. In order to be able to serve several clients simultaneously server is made parallel: each client is served by a separate server process, which is forked by CAMAC daemon after establishing connection. Server processes communicate and synchronize with each other through the System V shared memory and semaphores IPC mechanisms, available in various Unix clones and, particularly, in Linux. CAMAC hardware is accessible for server processes through calls to CAMAC interface card driver.

It should be noted, that CAMAC protocol is designed in such way that users can perform CAMAC operations not earlier than they reserve a slot or set of slots for their purposes. It is especially important in multi-user training system. Only one client can exploit particular slot, until this client wishes to release the slot when it is not needed for the client anymore. This prevents users from disturbing each other.

We also implemented several simple client programs, which are used for various purposes, for example, testing CAMAC server. Among these one can mention client for Linux operating system (CAMAC shell) with a command line user interface and client with a GUI interface for Windows family operating systems. Both these programs allow users (for example, students) to connect to CAMAC server, capture and release CAMAC slots and perform low level CAMAC operations, both addressable, such as reading data from modules and writing data to modules, and nonaddressable, such as Z (initialize) and C (clear) commands.

USING THE SOFTWARE IN TEACHING TASKS

In order to familiarize students with basic principles of CAMAC hardware programming one can use several approaches. First, manual crate controller combined with dataway display and word generator can be used. When using such a controller, teachable persons program CAMAC modules by pressing buttons on the front panel of the controller and word generator. This method has the advantage that such a way of programming provides the closest possible contact with hardware. The main disadvantage of this method is that it is not quite convenient: in order to set, e.g. the value of data word to be written to a CAMAC module, one have to press corresponding buttons on the word generator, which is not very convenient in case when binary code is used. Second, one can use the program library, which allow interacting with CAMAC hardware. In this case students program CAMAC modules using this library and some high level programming language, such as C or Pascal. This way of teaching has the drawback, that students must be familiar well with the language. If this is not the case, they sometimes have to pay too much attention to programming itself and cannot focus on programming CAMAC. Third way to teach CAMAC programming is to use ready software, which allow to perform low-level CAMAC operations. The CAMAC clients mentioned above and CAMAC server can be classified as such sort of software. Using this approach has several advantages by comparison with the previous two methods. First, it is quite close to the hardware, almost as the using manual controller, except that in this case CAMAC cycle cannot be performed in step-by-step mode. At the same time it is much more convenient and faster. Second, it does not require knowledge in programming languages (this does not mean, of course, that students should not know any programming languages at all, but if the goal is to make students acquainted with CAMAC, such a way of teaching seems to be quite reasonable and relevant for this purpose). Third, it provides for remote access to CAMAC hardware.

Using the last approach, we have elaborated training system on the base of the CAMAC server whose purpose is to introduce students to the basics of management of the CAMAC equipment as well as to the methods of organization of remote access to automatic experimental setup.

A short description of the lab work 'Studying CAMAC modules' is used here as an example of usage of this system. This lab study is fulfilled with the help of Windows CAMAC client program, which acts almost as manual CAMAC crate controller. This work is designed for the 3rd year students of the Physical Faculty studying the 'Automated systems for scientific researches' course. CAMAC modules used in the remote training system are connected to the automatic experimental setup, which is used for studying processes of atom-atom collisions by methods of optical spectroscopy.

The goal of this laboratory study is to get introduced to the principles of CAMAC system architecture and to gain some practical skills in working with CAMAC modules.

In order to be able to complete this lab study, students have to go through their lecture materials on data exchange on CAMAC bus, including timing diagram of bus signals during CAMAC cycle. In addition to that they also have to study the structure of crate controller, instructions on how to operate it, and also technical characteristics and commands of CAMAC modules according to the variants of the lab study given to every student.

The assignment includes a number of tasks, which differ in a set of functional modules. Binary-decimal counter and synchronizing timer, for example, is used in one of the tasks, ADC and DAC converters – in another and so on.

Having studied principles of module operation as well as it’s functional purpose and commands by which it can be controlled, students then have to develop an algorithm of how to perform the task and then, using the Windows client program, which simulates the crate controller, get done an assignment, making sure that all of the commands are being executed by particular module properly.

When accomplishing their tasks students connect to the CAMAC server from their personal computers. Having established connection each user with a special command reserves CAMAC modules assigned for him that allows to avoid an access to those modules by other users.

It has been mentioned before that client, which is used to accomplish the lab study, allows a student to generate Z, C and NAF CAMAC commands. Most of the work is done by manipulating well-known controls such as buttons, menus, combo boxes, etc. For example, sending commands to modules include choosing slot and crate numbers, internal module address and function to be executed from a set of combo boxes and pressing 'EXECUTE' button with a mouse click. After each command server returns the content of the control and status register of create controller to the user and, in case of the read command, three bytes of data. If a user acts incorrectly server returns error code. Analyzing contents of the control and status register, a student is able to determine values (active/nonactive) of X, Q and I signals, and also to determine bits' states set by the previous command. As a result users receive the same information as they would when using dataway display.

At the end of the work students have to answer to a number of additional test questions concerning CAMAC system. Also students are suggested to plan some physical experiment automated on the base of CAMAC system and think of what sort of CAMAC modules one would use in this experiment.

We have discussed one of the most simple laboratory studies. Senior students have to do more complicated assignments. Students with Masters degrees studying the 'Technologies of remote access to physical equipment' course have to develop protocol by themselves and to write both server and client program that would manage some experiment.

We would like to stress that the distinctive feature of the system described is that it allows active interaction of the student with real equipment. That helps not only to acquire a certain amount of knowledge as when reading books, no matter, printed or electronic, but also to verify whether knowledge acquired were deep and correct. To be able to reach the goals of the assignments it is necessary to have knowledge of both syntax of commands (system will refuse to perform illegal commands and return error message) and principles of structure and operation of the modular automated system (functioning set of modules will output true data only under proper usage). Automatic control of knowledge can be enriched with the help of communication of different electronic forms between students and a teacher, such as e-mail or ICQ. As long as the help of the teacher is needed only in very difficult cases live communication can be substituted by modern means of communication that can easily be integrated with the system described. Practice showed that written narration of the problem helps students to deeper understand the assignment and even to find a correct answer themselves.

CONCLUSION

In a conclusion we would like to say that CAMAC server developed by authors was successfully utilized for building training system, which in turn was used for organizing laboratory studies on various topics, including 'Studying CAMAC modules' and 'Remote control of data acquisition system'. In conjunction with the client programs, the server is used to help students in acquiring basic skills in CAMAC hardware programming. Notice that combination of the server with similar client programs may be useful for lecture demonstration of ideas of how to work with CAMAC based data acquisition system.

Finally, the approach discussed in this work can easily be extended to other types of modular data acquisition hardware.

ACKNOWLEDGMENTS

We would like to express gratitude to prof. A. D. Khakhaev and chief of laboratories I. P. Shibaev for support of this work.

AS NOVAS DIRETRIZES CURRICULARES NO BRASIL: DESAFIOS

Antônio Cláudio Gómez de Sousa[1]

Abstract *— The new directives for engineering education in Brazil was recently approved and published. These new directives define the subjects of the engineering courses, the competencies and skills that we desire for engineers. They allow diversity of curriculum and flexibility of curriculum structure. This paper analyzes the improvements of the new directives, issues discussed but not included, and the challenges put by the new directives: how to qualify the engineers to develop new technologies, actuate critical and creatively, have ethical and humanistic vision to satisfy the social demands, and identify and solve the problems considering the political, economical, social, environmental and cultural aspects. Finally examines the new directives and the tendencies of the engineering in the world.*

Index Terms — currículo, diretrizes, educação, ensino

INTRODUÇÃO

No dia 25 de fevereiro deste ano foi publicado no Diário Oficial da União o Parecer CNE/CES 1.362/2001 [9], que estabeleceu as "Diretrizes Curriculares Nacionais dos Cursos de Engenharia". No dia 9 de abril, também deste ano, foi publicada a Resolução CNE/CES 11 [10], que instituiu as "Diretrizes Curriculares Nacionais do Curso de Graduação em Engenharia". Estes dois documentos definiram as novas diretrizes curriculares para os cursos de graduação em engenharia. Foram produzidos a partir de discussões na comunidade interessada no assunto, e traduzem, em boa medida, o que se discutiu em vários fóruns de debate, como se pode ver consultando os anais dos últimos Cobenge [7] [8], de outros congressos, como os "Encontros de Educação em Engenharia", fóruns de reitores, congressos de educação de variadas áreas do conhecimento, e documentos produzidos por várias universidades ou escolas de engenharia. As novas diretrizes colocaram novos desafios que devemos enfrentar. Este trabalho pretende destacar a evolução das diretrizes, os desafios e as formas de superá-los. Para isso iniciamos apresentando a legislação anterior; depois discutimos os princípios sobre os quais devem se basear as diretrizes curriculares; a seguir apresentamos as novas diretrizes; depois suas falhas; na parte mais importante discutimos os desafios colocados pelas novas diretrizes curriculares; finalmente na última seção apresentamos as principais conclusões deste trabalho.

A LEGISLAÇÃO ANTERIOR

A legislação anterior era baseada na Resolução 48/76 [1] de 1976 do Conselho Nacional de Educação. Ela estabelecia o currículo mínimo para as várias modalidades de engenharia quanto ao conteúdo, e estabelecia certos mínimos quantitativos, como a quantidade mínima de horas dos cursos, e o tempo mínimo de integralização curricular. Definia os conteúdos como matérias, e as Instituições de Ensino Superior deveriam incluir essas matérias em suas disciplinas, o que conferia certa flexibilidade para a organização dos currículos. Sua concepção de currículo era portanto de grade curricular.

As modalidades em engenharia eram divididas em um conjunto pequeno e fixo de habilitações, e as novas modalidades, ou variações, eram definidas como ênfases das habilitações. Essa estrutura, e sua nomenclatura, recebiam forte influência do exercício profissional, com prejuízo para a flexibilidade curricular.

A LDB

Em 20 de dezembro de 1996 foi publicada no Diário Oficial da União a lei 9.394 [5], conhecida como LDB, que estabelecia as Diretrizes e Bases da Educação. Essa lei desacopla o diploma de curso superior do exercício profissional, ao estabelecer em seu artigo 48 que *"os diplomas de cursos superiores tem validade como prova de formação recebida"*.

Ela estabelece também diretivas gerais para a educação que devem ser consideradas, pois tem relação imediata com nossa discussão sobre as diretrizes curriculares para os cursos de graduação em engenharia. Em seu início está posto que a educação deve ser "*inspirada nos princípios de liberdade e nos ideais de solidariedade humana, tem por finalidade o pleno desenvolvimento do educando, seu preparo para o exercício da cidadania e sua qualificação para o trabalho*". A seguir apresenta vários princípios básicos para o ensino, entre os quais a "*liberdade de aprender, ensinar, pesquisar e divulgar a cultura, o pensamento, a arte e o saber, o pluralismo de idéias e de concepções pedagógicas, a garantia de padrão de qualidade, a valorização da experiência extra-escolar, e a vinculação da educação escolar com o trabalho e as práticas sociais*". Com esses princípios a LDB estabelece uma visão da educação para a cidadania, que retomaremos mais adiante ao discutir as novas diretrizes curriculares.

PRINCÍPIOS PARA A ELABORAÇÃO DE CURRÍCULOS

Uma discussão mais completa deste item pode ser encontrada em [8] e [12]. Vamos aqui começar por uma questão sempre colocada: a formação de engenheiros "adaptados" ao mercado de trabalho. Concordamos com essa questão, mas temos de discutir como se dá essa adaptação. Não de deve submeter os recém formados ao mercado profissional, de forma a terem sucesso em sua inserção nesse mercado, numa visão imediatista e individualista de sucesso. Em primeiro lugar porque se prepararmos, hoje, um currículo para o mercado atual, quando os alunos saírem, daqui a cinco anos, o mercado terá mudado e a adaptação terá sido destruída. Em segundo lugar porque a visão de sucesso deve ser social. Formamos engenheiros para utilizar os conhecimentos científicos e tecnológicos para melhorar o bem estar das pessoas, e fazer avançar a sociedade para outra sociedade mais solidária, humanista e em equilíbrio com a natureza. Em terceiro lugar porque o mercado evolui, e o engenheiro deve acompanhar ou estar à frente dessa evolução, portanto preparado para a evolução. Lopes [6] e Sousa [2] [3] propõem formar profissionais vinculados ao mercado de trabalho de uma forma crítica, de maneira que eles sejam fatores de inovação, uma massa crítica necessária para se chegar a uma nova sociedade.

Uma segunda questão é como preparar nossos egressos para que acompanhem a evolução dos conhecimentos tecnológicos, e sejam criativos nesse processo de produção de novos conhecimentos. Como a tecnologia está apoiada em algumas ciências, como a matemática, a física, a química e a biologia, entre outras, os currículos devem ter um forte embasamento nessas ciências, de maneira a dar aos egressos condições para dominarem as tecnologias e seus porquês, assim como sua evolução. Ao lado desse embasamento, é importante formar os engenheiros com uma atitude pró-ativa, renovadora, compromissada com a evolução dos conhecimentos e apta a produzi-los. Para atingir essa formação, desde o início o projeto pedagógico definido no currículo deve colocar a iniciativa do aprendizado no aluno, e em suas relações com o professor e os demais alunos. Um currículo pode ter lacunas no conteúdo, mas se o engenheiro for formado com iniciativa e forte base científica, poderá sanar essas lacunas. No entanto com falhas no embasamento ou na atitude pró-ativa, será um engenheiro estagnado.

Uma terceira questão refere-se aos desafios colocados atualmente para os que trabalham em tecnologia. Temos hoje conhecimentos tecnológicos para resolver os problemas básicos da sociedade, no entanto eles estão sendo agravados e está aumentando o fosso entre os indivíduos. A fome e a miséria nunca foram tão grandes, apesar de termos avanços espetaculares na bioengenharia, na nanotecnologia, na informática, nas telecomunicações, etc. Em reforma realizada em 1992 no "Worcester Polythechnic Institute", de Massachussets, EUA, foi considerado que o desafio central da engenharia americana era dominar o impacto da mesma sobre a sociedade americana [4]; por isso resolveram que na grade curricular, em todos os períodos do curso, pelo menos um terço do tempo seria dedicado a disciplinas da área de ciências humanas, exatamente para discutir com os alunos o impacto da tecnologia sobre a sociedade americana, e prepará-los para uma atuação socialmente inserida.

Uma quarta questão é a integração dos conhecimentos. Por uma questão de organização do currículo em disciplinas, o conhecimento necessário a um engenheiro é dividido entre as disciplinas. Na análise de sistemas sabemos que se dividirmos um sistema complexo em muitas partes, a agregação dessas partes não recupera todo o sistema original, pois algumas características do sistema poderiam estar apenas no todo. Com as disciplinas acontece algo similar. Cada disciplina é lecionada como algo estanque, com seus objetivos próprios, não está integrada em um processo orientado pelo perfil de engenheiro que se deseja formar. Ao "passar pelas disciplinas" os alunos muitas vezes não conseguem ver seus inter-relacionamentos, pois foram quebrados no particionamento do conhecimento em disciplinas. É necessário organizar atividades explícitas no currículo para a integração do mesmo, visando recuperar a visão global do conhecimento do engenheiro.

Uma quinta questão é a disputa entre formação especializada e formação generalista. Considerando a constante evolução da tecnologia e a necessidade de se ver a engenharia dentro de um contexto mais amplo, como está analisado em [2] e [3], deve-se optar por uma formação generalista que permita ao engenheiro trabalhar em novas áreas, em áreas interdisciplinares, desenvolver conhecimentos e se relacionar com outras áreas do conhecimento. A opção pela formação generalista não significa que não poderemos ter modalidades na engenharia. Elas podem existir, mas em toda modalidade deve-se trabalhar com uma visão generalista de engenharia, mesmo que isso provoque muitas sobreposições de conteúdos, principalmente dos conteúdos básicos.

Uma sexta questão retoma a visão crítica da engenharia. Algumas vezes os conhecimentos tecnológicos ou científicos são vistos e postos como verdadeiros, independentes da sociedade e neutros. O conhecimento em si não é bom ou mau, mas seu uso pode ser bom ou mau. Ao tomar uma decisão tecnológica, o engenheiro deve ter uma visão crítica que lhe permita ver a quem essa opção beneficia, a quem prejudica. Decisões podem ter fortes impactos positivos ou negativos sobre a sociedade ou sobre a natureza. Recentemente um navio petroleiro afundou nas costas da Espanha, vazando óleo e provocando novo desastre ecológico. Não foi a primeira vez, e sempre o desastre ambiental foi provocado pelo fato de serem navios sem duplo casco. A tecnologia do duplo casco permite que o óleo fique confinado nos tanques dos cascos internos, mesmo no caso de rompimento do casco externo. Portanto essa tecnologia já é conhecida, e esse novo acidente ambiental poderia ter sido evitado. Não o foi porque, por pressão dos grandes armadores, a exigência do duplo casco para navios petroleiros só será efetiva a partir de 2015. Sob o ponto de vista tecnológico podemos fazer navios com ou sem duplo casco, mas sob o ponto de vista ecológico está evidente que deve se optar pelo duplo casco. Se isso não é feito, é por interesses comerciais que se sobrepõem aos interesses ambientais.

AS NOVAS DIRETRIZES CURRICULARES

As novas "Diretrizes Curriculares Nacionais dos Cursos de Engenharia" [9], definem que "*o perfil dos egressos dos cursos de engenharia compreenderá uma sólida formação técnico científica e profissional geral que o capacite a absorver e desenvolver novas tecnologias, estimulando a sua atuação crítica e criativa na identificação e resolução de problemas, considerando os seus aspectos políticos, econômicos, sociais, ambientais e culturais, com visão ética e humanística, em atendimento às demandas da sociedade*". Definem também que os currículos deverão dar condições a seus egressos para adquirir competências e habilidades para:

- aplicar conhecimentos matemáticos, científicos, tecnológicos e instrumentais à engenharia;
- projetar e conduzir experimentos e interpretar resultados;
- conceber, projetar e analisar sistemas, produtos e processos;
- planejar, supervisionar, elaborar e coordenar projetos e serviços de engenharia;
- identificar, formular e resolver problemas de engenharia;
- desenvolver ou utilizar novas ferramentas e técnicas;
- supervisionar a operação e a manutenção de sistemas;
- avaliar criticamente a operação e a manutenção de sistemas;
- comunicar-se eficientemente na forma escrita, oral e gráfica;
- atuar em equipes multidisciplinares;
- compreender e aplicar a ética e responsabilidade profissional;
- avaliar o impacto das atividades da engenharia no contexto social e ambiental;
- avaliar a viabilidade econômica de projetos de engenharia;
- assumir a postura de permanente busca de atualização profissional.

Na estrutura do curso, as diretrizes exigem que cada instituição defina seu projeto pedagógico especificando como garantirá o perfil desejado dos egressos. Apontam para uma redução do tempo em sala de aula, para trabalhos de síntese e integração do conhecimento e para trabalhos complementares extras-classes como iniciação científica, estágios, visitas, projetos multidisciplinares, desenvolvimento de protótipos, monitorias, etc.

Quanto ao conteúdo, definem um "*conteúdo básico*", com cerca de 30% da carga horária, que deve versar sobre um conjunto enumerado de tópicos. Definem "*um núcleo de conteúdos profissionalizantes*" com cerca de 15% da carga horária mínima, que deve versar sobre um subconjunto de um conjunto de tópicos enumerados. Finalmente definem um "*núcleo de conteúdos específicos*" que devem caracterizar a respectiva modalidade, de livre escolha por parte das IES. O estágio curricular já previsto na Resolução 48/76 [1] é mantido, mas sua duração passa de 30 para 160 horas. Torna obrigatório o trabalho final de curso como atividade de síntese e integração de conhecimento.

A Resolução CNE/CES 11/2002 [10], publicada no Diário Oficial de 9/4/2002, regulamentou as diretrizes na forma de uma resolução, com seus artigos repetindo o que está definido nas diretrizes. Seu artigo 8o, no entanto, acrescenta a exigência de avaliação dos alunos por parte das IES baseada nas habilidades, competências e conteúdos curriculares definidos pelas diretrizes, assim como exige a avaliação dos cursos baseada nos mesmos princípios curriculares. Introduz portanto uma novidade em relação à avaliação dos alunos e dos cursos.

O documento que foi publicado divulgando as novas diretrizes é antecedido de um relatório que tem três trechos que vale a pena repetir.

O primeiro trecho define o novo engenheiro: "*O novo engenheiro deve ser capaz de propor soluções que sejam não apenas tecnicamente corretas, ele deve ter a ambição de considerar os problemas em sua totalidade, em sua inserção numa cadeia de causas e efeitos de múltiplas dimensões*".

O segundo trecho se refere à estrutura dos cursos de engenharia: "*As tendências atuais vêm indicando na direção de cursos de graduação com estruturas flexíveis, permitindo que o futuro profissional a ser formado tenha opções de áreas de conhecimento e atuação, articulação permanente com o campo de atuação profissional, base filosófica com enfoque na competência, abordagem pedagógica centrada no aluno, ênfase na síntese e na transdisciplinaridade, preocupação com a valorização do ser humano e preservação do meio ambiente, integração social e política do profissional, possibilidade de articulação direta com a pós-graduação e forte vinculação entre teoria e prática*".

Finalmente o terceiro trecho se refere ao Projeto Curricular: "*Na nova definição de currículo, destacam-se três elementos fundamentais para o entendimento da proposta aqui apresentada. Em primeiro lugar, enfatiza-se o conjunto de experiências de aprendizado. Entende-se, portanto, que Currículo vai muito além das atividades convencionais de sala de aula e deve considerar atividades complementares, tais como iniciação científica e tecnológica, programas acadêmicos amplos, a exemplo do Programa de Treinamento Especial da CAPES (PET), programas de extensão universitária, visitas técnicas, eventos científicos, além de atividades culturais, políticas e sociais, dentre outras, desenvolvidas pelos alunos durante o curso de graduação. Essas atividades complementares* *visam ampliar os horizontes de uma formação profissional, proporcionando uma formação sociocultural mais abrangente. Em segundo lugar, explicitando o conceito de processo participativo, entende-se que o aprendizado só se consolida se o estudante desempenhar um papel ativo de construir o seu próprio conhecimento e experiência, com orientação e participação do professor. Finalmente, o conceito de programa de estudos coerentemente integrado se fundamenta na necessidade de facilitar a compreensão totalizante do conhecimento pelo estudante. Nesta proposta de Diretrizes Curriculares, abre-se a possibilidade de novas formas de estruturação dos cursos. Ao lado da tradicional estrutura de disciplinas organizadas através de grade curricular, abre-se a possibilidade da implantação de experiências inovadoras de organização curricular, como por exemplo, o sistema modular, as quais permitirão a renovação do sistema nacional de ensino*".

FALHAS DAS NOVAS DIRETRIZES

Nas várias discussões sobre as diretrizes, além das competências e habilidades que definiam o novo perfil do engenheiro, foram incluídas também as atitudes esperadas desse novo profissional. Essas atitudes apresentadas nas propostas da Abenge, foram descritas em [8] como compromissos com:

- A socialização do conhecimento e a pluralidade de concepções;
- As necessidades sociais da maioria da população e a luta contra toda forma de exploração, opressão ou discriminação dos seres humanos;
- A ética profissional e a responsabilidade social e ambiental;
- A inovação e a atualização profissional permanente;
- Uma postura pró-ativa e empreendedora;
- A defesa das culturas e da sociedade brasileira.

Destes itens o único mantido foi o da atualização permanente. Alguns podem ser lidos nas entrelinhas do relatório, mas não permaneceram explicitamente nas diretrizes. Esta foi uma perda que muito prejudicou as diretrizes, pois definia o perfil de um profissional integrado a seu ambiente social, e com compromissos bem claros.

As diretrizes não quantificaram também a carga horária mínima do currículo, assim como seu tempo de integralização mínimo. Essa nos parece uma outra falha, pois o estudo de engenharia tem um tempo de maturação que deve ser respeitado. A própria lei ao se referir aos conteúdos, fixa percentuais para esses conteúdos, porém ao não estabelecer um tempo mínimo, deixa esses percentuais sem referências, podendo variar muito em valores absolutos, dependendo da carga horária total de cada curso.

No terceiro trecho do relatório, apresentado na seção quatro deste trabalho, foi colocado como esperança de renovação do sistema nacional de ensino, a possibilidade dos cursos seqüenciais. Essa afirmação é no mínimo discutível, pois os cursos seqüenciais podem entrar em contradição com os princípios defendidos pelas próprias diretrizes. Por exemplo, a integração curricular será mais difícil com módulos seqüenciais, pois estes reforçarão a segmentação do conhecimento em engenharia em módulos coesos, mas com pouco acoplamento com os demais. A vantagem da terminalidade dos módulos seqüenciais seria oferecer formações aplicáveis imediatamente. Exatamente por esta característica será difícil de introduzir módulos de ciência básica, módulos com interdisciplinaridade, módulos com integração com visões sociais e ambientais. A tônica nos currículos modulares será de módulos que "agreguem valor" ao estudante sob o ponto de vista profissional, portanto com visão tecnicista de aplicação imediata.

OS DESAFIOS

Apesar das críticas colocadas acima, as novas diretrizes curriculares são um avanço, se comparadas às anteriores. Elas consideram o currículo não como uma grade curricular, mas como o conjunto das atividades desenvolvidas para a formação dos engenheiros, e colocam no centro do currículo o perfil do profissional que devemos formar. Exatamente por estes motivos, as diretrizes colocam o desafio de como atingir o perfil definido. Para vencer esse desafio vamos discutir várias propostas.

Para formar um engenheiro pró-ativo, empreendedor, inovador, necessita-se de um projeto pedagógico que coloque o aluno, e suas interações, como o centro do processo educacional. A iniciativa educacional deve estar no aluno, com a orientação do professor. Podemos manter aulas tradicionais, expositivas, mas o centro do processo educacional deve ser baseado em atividades com ampla iniciativa por parte do aluno e com a orientação do professor, ou mesmo de outros alunos mais adiantados. Esta é uma evolução a ser tentada, sabendo-se que os professores não estão preparados para esse tipo de método. Em geral os professores repetem os métodos de seus antigos professores, baseados em aulas expositivas. Quando questionados sobre o método de ensino, em geral afirmam que ele é bom, mesmo que hoje 50% dos alunos de engenharia desistam e não completem o curso. Há portanto a necessidade de preparar os professores para essa nova proposta. Como o ensino não é valorizado nas universidades na mesma medida que a produção científica, é difícil convencer os professores a investir tempo para aprender novos métodos de ensino, principalmente quando interferem na relação com os alunos. A mudança nos métodos pedagógicos passa portanto pela valorização do ensino nas IES, e por esforços continuados na formação dos professores Há que se vencer também uma concepção simplista do ensino superior, que considera o domínio de um assunto como a condição necessária e suficiente para o ensino. Ela é necessária, mas não é suficiente. Para ensinar é necessário dedicar tempo e esforço, pois é uma atividade tão complexa como aprender. Para começar esta mudança, os espaços de discussão da educação em engenharia devem ser valorizados, assim como a atividade docente, e oferecidas facilidades para a formação dos professores.

Os currículos devem ser reformulados para permitir a interdisciplinaridade, fundamentalmente introduzindo disciplinas de humanidades nos currículos. Só essa medida no entanto não mudará a situação atual. Os estudantes não valorizarão essas disciplinas, se as IES continuarem a não valorizar essa área em suas atividades, se no cotidiano das IES não houver discussões sobre os problemas atuais da engenharia, que exijam os conhecimentos das áreas humanas. Sem isso, as humanidades serão vistas apenas como um verniz cultural que o engenheiro deve ter, mas não como uma base científica para uma visão crítica do trabalho do engenheiro na sociedade.

Outra possibilidade é incentivar que os aspectos sociais sejam discutidos em todas as disciplinas básicas e tecnológicas.

Um assunto interessante para discutir nos cursos de engenharia é a evolução do conceito de qualidade. Esse conceito começou como a conformidade de um produto com normas e exigências, evoluiu para o controle do processo de produção, na versão 2000 das normas ISO chegou ao que se chamou de "satisfação do cliente", portanto alargando o conceito de qualidade para toda a vida de um produto, e em alguns países o conceito de qualidade está integrando a relação dos produtos e dos processos de produção com a natureza e com a sociedade. Na Alemanha, por exemplo, a partir de 2004 as empresas serão obrigadas a receber seus produtos, ou o que restar dos mesmos, de volta. Este é o início da saída de um paradigma de processo de produção industrial que transforma bens naturais em bens artificiais para a satisfação das necessidades humanas, só num sentido, com o conseqüente esgotamento de recursos naturais e a degradação dos mesmos, para um outro paradigma em que o processo de produção deve estar em equilíbrio com a natureza. Podemos transformar bens naturais em artificiais, mas devemos aproveitar bens artificiais para gerar outros bens artificiais, como o aproveitamento de dejetos e lixos, e transformar bens artificiais novamente em bens naturais. Assim a qualidade de um processo será julgada não mais por seu produto, mas pela vida total do produto, e pelas interações desse processo e dos produtos com a natureza e com a sociedade.

Finalmente devem ser previstas na estrutura curricular atividades que integrem os conhecimentos desenvolvidos nas disciplinas do curso. O projeto final tornou-se obrigatório, o que é um bom passo, mas não é suficiente. São necessárias mais atividades durante o curso para realizar a integração dos conhecimentos.

CONCLUSÃO

As diretrizes curriculares foram um grande passo. O desafio agora é fazer com que os cursos de engenharia formem egressos com o perfil definido nas diretrizes. Neste sentido a valorização do trabalho docente e a inserção das IES na discussão dos problemas da engenharia atual são aspectos fundamentais. Sem esses aspectos será difícil mudar os projetos pedagógicos, e não chegaremos a engenheiros críticos, inovadores, pró-ativos e conscientes de suas responsabilidades sociais e ambientais. Ao mesmo tempo deve-se procurar facilitar a formação docente para a educação em engenharia, para permitir novas formas de ensino/aprendizado que coloquem o aluno e suas interações como elementos centrais no processo educacional.

O desafio é colocar a engenharia a serviço da sociedade, preservando a natureza. O desafio é utilizar a imensa capacidade transformadora acumulada pela humanidade a seu serviço. Este é o nosso desafio.

SUPPORT SERVICE TO DISTANCE STUDENTS: THE IMPLEMENTATION PROCESS IN ONE BRAZILIAN DISTANCE EDUCATION INSTITUTION

2003

Marialice de Moraes[1], Ricardo Miranda Barcia[2]

Abstract *-The Distance Education Laboratory – LED, offers the structure and support to the distance education courses offered by the Post Graduation Program in Production Engineering – PPGEP. In order to offer the best support to its students, the Laboratory created a support structure based in collaborative work, where teachers and students are followed by a team from the beginning to the end of the course, as well as prepared to the correct utilisation of the media/technologies adopted. This article introduces the student support service model being implemented in the Distance Education Lab since 1997.*

Index Terms — *Distance Education,Internet, student support services, videoconference.*

INTRODUCTION

The widespread use of Distance Education – DE in Brazil observed from the beginning of the 90´s until now may be related to the changes in the regulatory process of Education, most specifically the so-called Lei de Diretrizes e Bases da Educação –LDB, that is the most important law regarding Education in Brazil was launched as Law 9.394, from December 20 1996 and is being continually refined in order to attend specificities identified by represented categories, and practitioners. One of the important points in this law is related to Teacher's Education, stating clearly that all teachers must have at least a College degree in order to work in K-12 education, and a Masters degree to work in universities, at the graduation level. For this reason, a significant amount of DE initiatives in Brazil are structured in order to attend this demand created by the LDB, and oriented to the improvement of Teacher's Education using different structures and media, and basically inside traditional universities.

So, the demand for DE reflects the changes that challenged Brazilian Education during the last decades, and the changes the country is passing through right now, that make the demand for professionals with a wide and specialized formation grow in an exponential way. There is a urge to supply the demand for places in Education for the adult workers looking forward to improve their formation, and to attend the many ones that had to leave school early in their lives to work, or for any other reason. They all have the right to Education, and the public and private institutions are making many efforts in order to get every one that needs or wants to study inside a classroom – traditional or virtual.

In this article, we describe some aspects of the experience of the Distance Education Laboratory –LED, of the Federal University of Santa Catarina –UFSC, a traditional public university located in Florianópolis, South of Brazil. In a open view, the experience with DE being developed in the UFSC is attending a identified demand related to very specific and technical areas, but if analysed more closely, that experience is also attending the demands for Teachers Education, and general Adult Education. Our main focus inside this experience is the implementation of the student's support services structure, describing the process, and the role of the professionals involved in this work. That is the purpose of this paper.

STUDENT SUPPORT SERVICE IN DISTANCE EDUCATION

The fundamental importance of an organised student's support service has been pointed out by many authors writing in the DE (Distance Education) field [1]; [2]; [3]; [4]; [5]. However, if there is agreement about the importance of such a structure, there is no definitive model for that. Each DE institution will invest in the development of its own model based on the characteristics of the students it serves [6]; [7]; [8]; [9].

There is an established necessity to offer support services for distance students, since these are pointed as the main alternative to reduce the high rates of dropout that characterizes DE. In the 2001 ICDE – International Council of Distance Education Conference in Düsseldorf, Germany this discussion

[1] Marialice de Moraes, Coordination of Student Support and Research, Distance Education Laboratory, Campus Universitário, Trindade, CX. 5090, (48) 331721, Florianópolis, SC, Brazil, mariali@led.ufsc.br
[2] Ricardo Miranda Barcia, General Director, Distance Education Laboratory, Campus Universitário, Trindade, CX. 5090, (48) 331731, Florianópolis, SC, Brazil, rbarcia@led.ufsc.br

was the main theme of the sessions dedicated to student support, where the majority of the works presented exposed the long range planning to reduce the scaring dropout rates using student support, especially in the case of the Mega Universities as the Open-UK [10]. Also, [6] showed the dropout numbers at the Athabasca University, Canada, that rise to 75% in order to illustrate how important is for any DE institution a well organised student's support structure.

Still pointing out the importance of the student support services in DE, the work of Ormond Simpson [4] describes how the student support service is organized in the OUK (Open University – UK), one of the most widely recognized DE institution in the world. Also, [4] pointed out that in Open and Distance Learning (ODL) the student support services may be related to a wide range of activities, from counseling to academic orientation. However, this tendency to define this area in a very open way does not deny its importance in DE. It implies that it is a really wide area, and according to [11], it involves activities before the student even registered to the course or discipline, like information about the courses, the University/institution, and about studying at a distance.

The importance of this area for the success of any DE initiative also appears in [12], where that author affirms that "We must aim for the provision of services which are appropriate to the external cohort we are serving, while recognizing that we should not attempt merely to replicate on-campus learner support services via technology" (75).

STUDENT'S SUPPORT SERVICES IN THE DISTANCE EDUCATION LABORATORY - LED

The creation of LED in 1996 was a direct result of the Strategic Planning established by the PPGEP in 1985, where the necessity to invest in new technologies, and new modalities to Engineering Education in order to be more close to the productive sector was underlined.

The moment when the LED was created was very favorable to the development of DE initiatives inside Brazilian universities, and more intensely applied to Post Graduation programs, since the existing demand was expressive [13]. Also, at that moment was very clear a growing demand for programs offered at a distance or with more flexible modalities in knowledge areas where the PPGEP was specialized, as Logistics, Entrepreneurship, and Media and Knowledge. Media and Knowledge is a teaching and research area that started to be developed in Brazil in the PPGEP, being related to the production and distribution of knowledge, DE, and the use of Information and Communication Technologies in Education.

In order to attend the identified demand a decision was made regarding the technologies to be used, and videoconference was selected as the core media to be used to offer Post Graduation courses at a distance. This choice was made based on the interactive possibilities of this media, that allows the synchronous communication by audio and video, of people that are located in different places. In a country with the Brazilian dimensions and cultural diversity, it proved to be very effective. Also, the established model used Internet based communication and information tools, and printed materials. Another important characteristic of the DE initiatives in the LED was the decision to make alliances and partnerships with different institutions and companies, aiming at the creation of a network that could attend all the Brazilian territory, offering the registered distance students the best possible service in their local place of study.

In this context, LED's "student support service" structure was created in July, 1997, when the first Post Graduation Program at a Distance, a Masters Degree to be offered to Engineers and technicians of Petrobras, the Brazilian Petrol Company was being implemented. This first program, called "Technological masters in Logistics", was the first structured experience of LED, served as the basis to the creation of the "Presencial Virtual" model, distinguished by the Brazilian Association of Distance Education (ABED) with it's Prize of Excellence in 2002. The perception that there was a need to offer technical, social, and administrative support to the students and teachers involved in the DE program led to the creation of the first working team that was responsible for the elaboration and distribution of supporting material – online manuals, guides, routines, calendar, etc. - and for the preparation of students and teachers to use the technologies adopted – videoconference and the Internet.

This initial phase was very intuitive since it was still difficult to find references in the available literature that could help to define the best pathway to be followed because of the very specific characteristics of the experience being developed – using videoconference, offering a complete Post Graduation program at a distance, attending working students. Also the benchmarking with Brazilian and international institutions working with DE showed that every single one has a different model, a different structure, specially in the area of student support. All of the previously quoted factors were very influential in the decision to develop a local model.

The first student support structure established in the Laboratory had only three professionals allocated to do all the work related. This group had a very wide array of responsibilities, and a great lack of references, of research to support their work. So, besides the direct work with students and teachers, this group started to make some related readings, benchmarking research, and to register the process, studying and learning, and gradually becoming a reference itself inside the Laboratory.

Until the end of 1997, LED offered technical and pedagogical support and structure for two Master's programs with a total of 49 students and not more than four professors for each trimester. However, in the first trimester of 1998, more three new programs had been implemented. As a consequence, the number of students to be supported started to rise. At that moment, the necessity of establishing a more organized and defined structure to support students and teachers involved in the programs was perceived as urgent. New professionals were contracted, and the role and function of the monitor (student supporter) started to be defined, the model of student support as monitory was implemented [14].

Once the importance of the student support structure was recognized, the team responsible for the students and teachers support in the LED was identified as the Monitoring and Research Team. Like all the other teams working in the Laboratory, this team is formed by professionals form very different backgrounds, like Sociology, Psychology, Engineering, and Pedagogy. All of them are Graduate students, and are doing their Master or Doctorate researches in areas related to DE, and Adult Education.

Since the "turning point" in 1998, where the fundamental questions were identified, the professionals working with student support inside the Laboratory are dedicated to three main lines of activities: informing, following, and answering students and teachers in the different models of courses offered, form Internet to printed materials. It is important to make it clear that in this work we are looking at the implementation process of the student support services in the Laboratory as a whole, but with a focus on the experience with Masters programs using videoconference and the Internet. These activities may be described as related to the keeping the students motivated, stimulating the communication and interaction among the students outside classroom time, and helping students and teachers to learn how to use the different media applied to the courses.

The importance of motivation to distance education students was discussed by some authors [15]; [16]; [17]; [18]. For this reason, the student support team invests in many activities to keep the students motivated, specially by using all the media the students have access to interact with them, and to make every student feel that there is somebody that is concerned with her/his success in the studies, sending motivational messages, helping and answering in a timely and cheerful way. The most important thing for a monitor is to establish a contact with the students he/she is responsible for, making them understand that they are part of a group, and that everyone is trying to make the best they can. To build that situation of empathy, the monitor that is responsible for a group usually has a face-to-face meeting with the students in the beginning of the course. This kind of activity already proved o be very important in order to create a sense of proximity and confidence between the students and their monitor [18].

The report wrote by [19] shows the results of a research done with a group of students of the Laboratory, where she found out that the motivational role of the support team is highly valued by the students, specially related to the utilization of the technologies (4.64 points in the used Likert scale), and in keeping the motivation (4.08 points in the used Likert scale).

An important point related to the motivational role of the LED's student support team is related to the practice of process evaluation established in the Laboratory since its creation, in 1995. All courses, and all disciplines offered are evaluated at least once. The process of evaluation is digitalized, where the students can access the online forms from any place, answer it, and in a very short period, have the answers of all the group analyzed together in a final report produced by the monitor. From 1997 to 2001, 71,2% of the disciplines offered where evaluated, and the results of this evaluation process used to solve the identified problems, and improve the process, attending the students demands [19].

Also, in the beginning of each new course a diagnostic evaluation is made, in order to have some basic information about the students, the so-called "Perfil da Turma", what helps the planning process, for the support team, and for the teachers involved. Knowing the students background, their previous experience with the media applied in the course, and their motivation to take the course, makes it easier to offer a personalized service to all students of the group.

The other two lines of activities developed by the LED's students support team - stimulating the communication and interaction among the students outside classroom time, and helping students and teachers to learn how to use the different media applied to the courses – may be seen as a unique block. In order to stimulate the communication of the group of students outside classroom time, the monitor is also stimulating the use of the different media adopted in the course. Using the Internet, or the telephone, or videoconference, the students may interact among them, do their activities in a cooperative and collaborative manner, contact the teachers, and exchange reference material, among other things. The role of the monitor (student supporter) is to make the students – and teachers – feel that all the technical or operational problems will be quickly solved, and that they can dedicate themselves only to learn and teach, always at a distance, but feeling close. It is important that the interactive communication process goes as smoothly as possible, so the mediating technology seems invisible [21].

CONCLUSION

LED's experience in offering DE courses, specially Post Graduation courses by videoconference and Internet, points up to the importance of offering to students and teachers a well structured support service, and well prepared professionals, trained to attend the constant demands in a timely and sympathetic way. A result of the work being done by the student support team in the Laboratory is the number of students that evaluated the support structure as Excellent or Very Good in the evaluations done since 1998 – 71% of the students enrolled [20].

It is important to say, in order to conclude, that the activities related to student support in DE cannot be seen as static, it is a dynamic process that needs to be permanently improved, adapted to new students, new situations, and specially, the new possibilities of communication and interaction at a distance offered by the new technologies, always evolving.

LEARNING STYLE IN THE CLASSROOM: A RESEARCH-GUIDED APPROACH

Teresa L. Larkin[1]

***Abstract* — *This paper will explore relevant research which documents that a learning style approach in the classroom can lead to enhanced learning gains. Particular emphasis will be placed on the Dunn and Dunn Learning Style Model. The basic tenets of this learning style model will be highlighted. The Dunn and Dunn model forms the basis of the Productivity Environmental Survey (PEPS) which is a valid and reliable learning style instrument. The PEPS is currently being used as a research tool within the introductory physics course for non-majors at American University. Two teaching approaches which have been developed based on a learning style approach will be shared. These approaches include the use of writing as well as interactive on-line discussions using Blackboard technologies. Ideas for effective adaptation of these approaches by educators in other branches of science, as well as mathematics, engineering, and technology (SMET) education will be discussed.*

Index terms — Learning style, writing, assessment, student learning, on-line discussions.

INTRODUCTION

The rapid changes that are continuing to occur in modern society, and in academia in particular, suggest that learning must be a continuous process. A growing body of research on adult learners suggests that increased learning gains can be achieved when instruction is designed with students' learning styles in mind [1]-[6]. In addition, several practitioners within the domain of physics as well as engineering education have noted the importance of teaching with learning styles in mind [7]-[14]. Attention to learning styles and learner diversity in the classroom has also been shown to increase student interest and motivation to learn. Increasing student interest and motivation to learn may lead to enhanced learning.

The particular population of students that encompasses the focus of this paper is non-science majors taking introductory physics at American University. Most students take this introductory physics course to satisfy the university's General Education Natural Sciences requirements for graduation. Because the backgrounds and ability levels of the group of students that elect to enroll in this course is quite broad-based and diverse, it is anticipated that the teaching and learning strategies to be described in this paper can be adapted for use with other populations of students as well. The underlying message is quite simple - a learning style approach CAN be successfully applied with ANY population of students.

This paper addresses the critical role that a learning style approach can play in terms of teaching introductory physics. A detailed overview of the learning style model used by the author will be provided. In addition, two specific teaching and learning strategies developed, in part, from current research on learning styles will be highlighted. These strategies involve extensive use of writing as a teaching and learning tool as well as the use of live, online chats using Blackboard technologies. Student perceptions regarding these strategies will also be shared. It is anticipated that these teaching and learning strategies can be adapted for use within the international community of science and engineering educators.

DESCRIPTION OF STUDENT POPULATION

The introductory course for non-science majors at American University in Washington, D.C. is entitled *Physics for the Modern World (PMW)*. PMW is a large enrollment, one-semester, algebra-based course. Topics covered in PMW typically include kinematics, Newton's Laws, conservation of momentum and energy, rotational motion, fluid mechanics, waves, and sound. Although traditional in its content, the course is not taught in a traditional lecture format. Many traditional teaching methodologies have clearly been shown to put students in the role of passive rather than active learning [15]. Numerous teaching strategies are used which correspond to the accommodation of students' needs and diverse learning styles [16]. The use of a variety of teaching strategies is very desirable, especially in a large enrollment course. In addition, the course includes strong conceptual and problem solving components.

PMW is a 3-credit course and consists of a lecture and a laboratory component. Students meet twice a week for class sessions that are 75 minutes long. On alternate weeks students meet for a two hour laboratory. Approximately 120 students, with 60 students in each of two sections, enroll in the course each semester. Of this enrollment, roughly 20% of the class is made up of international students.

Attention to learning style and learner diversity begins on the first day of class and continues throughout the semester.

[1] Teresa L. Larkin, Department of Computer Science, Audio Technology, and Physics, American University, 4400 Massachusetts Ave. NW, Washington, DC 20016-8058, tlarkin@american.edu

Students are given a learning style assessment on the first day of class. The assessment is completed by the students and returned for analysis during the next class period. The analysis process takes approximately one week at which time students are given an individualized learning style profile for their use. Students are also asked to write about their individual learning style preferences for their first writing assignment. Before a more detailed discussion of the specific teaching and learning strategies that utilize a learning style approach can be outlined, a description of learning style and the learning style model that is used in PMW will be presented.

LEARNING STYLE DESCRIBED AND DEFINED

What exactly is a learning style? Several definitions of learning style currently exist. Keefe [17] defined learning style as being characteristic of the cognitive, affective, and physiological behaviors that serve as relatively stable indicators of how learners perceive, interact with, and respond to the learning environment. Learning style is a gestalt of combining internal and external operations derived from the individual's neurobiology, personality, and development which are reflected in learner behavior. Learning style also represents both inherited characteristics and environmental influences.

Dunn [18] described learning style as "... the way each learner begins to concentrate, process, and retain new and difficult information" (p. 224). She noted that this interaction occurs differently for everyone. Dunn also highlighted that "To identify and assess a person's learning style it is important to examine each individual's multidimensional characteristics in order to determine what will most likely trigger each student's concentration, maintain it, respond to his or her natural processing style, *and* cause long-term memory" (p. 224). The assessment of individual student learning styles provides both the student and the instructor with valuable information regarding factors that influence learning.

Dunn [19] has suggested that the uniqueness of individual learning styles could be thought of as a fingerprint. She said "Everyone has a learning style, but each person's is different - like our fingerprints which come from each person's five fingers and look similar in many ways" (p. 27). Interestingly, Sternburg [20] indicated that an individual's learning style can be compared to her/his ability and is therefore not etched in stone at birth. In fact, a person's learning style can change over time as a result of maturation [21]. Kolb [22] has suggested that "As a result of our hereditary equipment, most people develop learning styles that emphasize some learning abilities over others." (pp. 76 – 77).

Dunn contended that strong preferences can change only over a period of many years and that preferences tend to be overcome only by high levels of personal motivation. She further asserted that teachers cannot identify students' styles without the use of appropriate instruments. Assessing an individual's unique style is vital to the teaching/learning process. A significant number of research studies have shown that students instructed in a classroom environment where individual learning differences are acknowledged and accepted are more receptive and eager to learn new and difficult information [23 – 28]. Dunn also suggested that a match between a student's style and a teacher's style will lead to improved student attitudes and higher academic achievement. A description of the Dunn and Dunn learning style model employed with students enrolled in PMW is given in the next section.

DESCRIPTION OF THE DUNN AND DUNN LEARNING STYLE MODEL

Many different learning style assessment models and instruments are available. De Bello [29] indicated some models are multidimensional, encompassing cognitive, affective, and psychological characteristics, and others are limited to a single variable, most frequently from the cognitive or psychological domain. This section will focus on the learning style model developed by Dunn and Dunn [30] as shown in Figure 1 and the associated learning style assessment instrument developed by Price, Dunn, and Dunn [31].

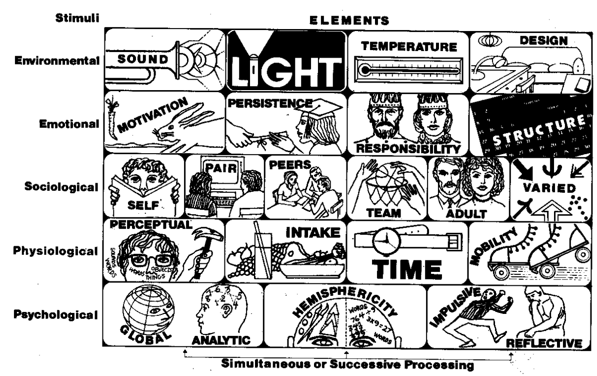

FIGURE 1.
THE DUNN AND DUNN LEARNING STYLE MODEL

Price, Dunn, and Dunn suggested that productivity style theorizes that each individual has a biological and developmental set of learning characteristics that are unique. They further suggested that improvements in productivity and learning will come when instruction is provided in a manner that capitalizes on an individual's learning strengths. Attention to learning styles does not mean that a student should only be taught through their strengths, however. The utilization of a variety of teaching strategies helps to ensure that students have an opportunity, at least a portion of the time, to learn new and difficult information through their strongest preferences while simultaneously allowing them an opportunity to build up and enhance their weaker preferences.

As a model, Price, et al. indicated that productivity style embraces several general principles that they state in the form of philosophical assumptions:

1) Most individuals are capable of learning.
2) The learning conditions in which different individuals learn best vary extensively.
3) Individual learning preferences exist and can be measured reliably.
4) Most students are self-motivated to learn when they have the option of using their learning style preferences and experience success.
5) Most teachers can learn to use individual learning styles as a basis for instruction.
6) When selected teachers are not capable of learning to use individuals' learning styles as a basis for instruction, students can be taught to teach themselves and, thus, bypass their teachers' styles.
7) Use of individual learning style strengths as the basis for instruction increases learning and productivity. (pp. 21 -22)

As De Bello noted, the basic tenet of the Dunns' model is that individual styles must be assessed, and, if a student is to have the best opportunity to learn, instructional techniques must be used that are congruent with each student's style. Not all theorists agree with this tenet because they feel it is extreme. Other theorists wrestle with the question of whether we should teach to an individual's strengths or try to help them develop their weaknesses. The best answer is actually both. One of the best ways, especially in large classes, to teach to individual students' strengths is to use a variety of instructional styles and modes of delivery.

The learning style assessment instrument chosen for this study is the Productivity Environmental Preference Survey (PEPS) by Dunn, Dunn, and Price. This instrument was chosen because of its comprehensive nature, and, because of the relative ease of assessing students and interpreting the results. The PEPS was developed from the Dunn and Dunn Learning Style Model and is described in the following section. As Figure 1 shows, the Dunn and Dunn Learning Style Model is based on five different stimuli: (1) Environmental, (2) Emotional, (3) Sociological, (4) Physiological, and (5) Psychological. These categories provide the basis for the elements displayed in the feedback profile obtained after student responses to the PEPS have been scored.

The Dunn and Dunn Learning Style Model has had widespread use with adult learners, however its use in physics as well as other branches of science and engineering education has been quite limited. As a result, the use of this model in physics, as well as in other branches of science and engineering education becomes even more interesting to study.

THE PRODUCTIVITY ENVIRONMENTAL PREFERENCE SURVEY (PEPS)

The PEPS consists of 100 questions on a Likert scale. This instrument uses a standardized scoring system that includes scores that range from 20 to 80. The scale is further broken down into three categories. These categories are referred to here as Low, Middle and High and are represented in Figure 2. The Low category represents standard scores in the 20 - 39 range; the Middle category scores in the 40 - 59 range; and the High category scores in the 60 - 80 range. Individuals who have scores lower than or equal to 40 or higher than or equal to 60 for a particular element find that variable important when they are working. Individuals who have scores in the Middle category find that their preferences may depend on many factors such as motivation and interest in the particular topic area being studied.

FIGURE 2.
RESULTS OF THE PEPS (REPRINTED WITH PERMISSION)

Looking at one specific example, within the category of environmental stimuli are the elements of sound, light, temperature and design (formal versus informal). The elements within this category are self-explanatory. This category is one that is difficult to accommodate in the classroom. However, learners can easily satisfy their preferences when working outside of class. For example, a score ≥ 60 for the element of sound would mean that an individual has a preference for sound when learning new and difficult information. An individual could accommodate their preference for sound by listening to soft music. A score ≤ 40 on the sound element would imply that an individual does not show a preference for sound and thus should work in a quiet environment (using earplugs if necessary). A score in the middle category means an individual might prefer sound at one time, and not at another. In this case, an individual's preference would depend on other factors.

Once the PEPS has been administered, students receive an individual feedback profile as quickly as possible. Students must immediately be made aware that no high or low exists on this scale in terms of superiority of scores. Furthermore, no scores are bad scores - all are simply unique. No scientific evidence shows that one type of learning style is academically superior over others.

Numerous research studies [32] have documented the reliability and validity of the PEPS. Dunn and Dunn [33] posited that research on their model is more extensive and more thorough than research on many educational topics. As of 1998 research utilizing their model had been conducted at more than 112 institutions of higher education, at all levels K - college, and with students at most levels of academic proficiency, including gifted, average, underachieving, at-risk, dropout, special education, vocational, and industrial art populations.

Dunn, et al. [34] performed a meta-analysis of the Dunn and Dunn model of learning style preferences. They reviewed forty-two different experimental studies conducted with the model from 1989 to 1990. Their results indicated that overall academic achievement of students whose learning styles have been matched can be expected to be about three-fourths of a standard deviation higher than those of students whose learning styles have not been accommodated. Further, when instruction is compatible with students' learning style preferences, the overall learning process is enhanced.

The need to identify individual learning styles through formal assessment has never been more important than it is at present. Instruction responsive to individual learning styles is especially critical as the pool of students who enroll in introductory physics classes becomes more and more diverse. The following section highlights two instructional approaches developed for use with introductory physics students. The underpinnings of each approach are grounded, in part, in the results of current research on learning styles.

TEACHING AND LEARNING APPROACHES: STRATEGIES TO ENHANCE STUDENT MOTIVATION AND INTEREST

All students enrolled in *Physics for the Modern World* at American University are given the PEPS at the beginning of the semester. Students receive a computerized individual feedback profile approximately one week after that. This profile is similar to a prescription in that it identifies categories (based on the Dunn and Dunn Model) in which students have strong preferences and gives them information as to how to best utilize these strengths. Students are also extended an invitation to visit with the instructor individually regarding their learning style profiles. The instructor also maintains a copy of each student's profile and makes use of that when working with them individually during office hours.

Teaching approaches utilized in the introductory physics course have been designed, in part, using the Dunn and Dunn Learning Style Model. Two unique teaching approaches will now be described. One approach involves a writing activity developed by the author called a *folder activity.* A second approach involves the use of a live, interactive, online chats that make use of Blackboard technologies. These approaches are described in the following sub-sections.

Approach (1): Writing Activities

The first teaching approach to be described involves the use of writing and is called a *folder activity*. Writing has long been established to be an effective means of expressing one's ideas, thoughts, and understanding about nature and the world. The folder activity was developed by the author more than 10 years ago to help students elicit and confront their misconceptions in physics in a non-threatening way [35]. This is particularly important as science classes are often viewed by many students as threatening and intimidating places to be. The folder activity also allows students to be creative and use their unique learning style preferences when they prepare their written responses. Writing can also be a very effective vehicle for allowing students to develop and enhance their critical thinking and problem solving skills.

As part of their homework assignments, students are required to keep a two-pocket folder. Students receive 5 - 10 writing assignments each semester. Upon collection of the folders, a block of time is set aside (approximately 6 - 8 hours) to read them and provide each student with written feedback. This direct written feedback is absolutely essential. When students take time to reflect on their writing and on the instructor's comments, the folder becomes a highly effective tool in helping them uncover and then wrestle with their misconceptions while the learning is actually taking place. Typical folder activities range in length from 1 - 4 pages. To eliminate some of the burden on the instructor of reading 120 papers at a time, assignments are sometime alternated between sections. For example, a folder assignment might be given to the first section *prior* to the introduction of a new topic, and the same assignment given to the second section *after* discussion of the topic has take place. This strategy allows the instructor to gauge where students are at in terms of their understanding of a topic before and after it has been covered in class. If the students' writing shows that they have not made the desired progress on a particular topic, additional class time can be devoted to reinforcing it.

The specific emphasis of the writing activities depends on the goals and objectives for a particular topic or content area. For example, for some activities students are asked to explain a problem or a concept that was highlighted or discussed during a class session. Thus, students essentially have the "answer" to the problem in their hands when they write up this folder assignment. The rationale for this type of activity is that learning can be enhanced when students take on the role of teacher through their detailed written responses and explanations.

An additional example of a typical folder activity involves the creation of sample exam questions. In addition to writing a question, students must explain their choice of responses (i.e. for multiple choice questions) including the reasoning behind both the correct response as well as the incorrect options. In some cases, exemplary student exam questions are organized and distributed to the entire class as a means of a review. The student sample exam questions are never actually used on a classroom quiz or exam. The questions are simply used to help enhance student understanding.

Students are always encouraged to share their understanding of a particular topic or concept in their own words. Thus, students are not pressured to bog their writing down with a lot of scientific jargon. This provides a much clearer window into the students' thoughts and to their level of understanding and often offers deeper insight than can be ascertained from traditional paper and pencil assessments. Interestingly, as the semester progresses, the students begin to naturally make correct use of more sophisticated scientific terminology in their writing.

An important aspect of the folder activities is that students are permitted to be as creative as they would like to be. They are encouraged to write their responses in a fashion that allows them to make use of their individual learning styles. For example, some students like to enhance their writing through the use of manipulatives and artistic drawings. Other students choose to write their responses in the form of a story, a poem, or a short play. Students know that they have complete control of this activity and are free to put their learning styles to good use. Students also know that they don't receive any type of "bonus" for being creative. However, allowing a good of flexibility with the format of the writing offers more students an opportunity to demonstrate their understanding of a topic or concept in a manner best suited to their particular styles of learning.

The assessment of the folder activities is somewhat unique in that students are not penalized for incorrect use of physics. Not penalizing students helps make the folder activities non-threatening. The written feedback provided by the instructor indicates to the students that their writing is taken very seriously, and that it should be used as a vehicle to promote understanding. In addition, numerical scores are not put on students' papers until the end of the semester. The intent here is to get the students to pay attention to the written feedback from the instructor and not the grade they received. For example, if a student received a score of 17/20 on an assignment they might be tempted to say to themselves "Well, 17/20 is a pretty good score, I'm happy with that" and then never look at the assignment again. Then later on, the 3 points they missed come back to haunt them on an exam, only the 3 points have now magnified into many more points.

The bottom line is that students need to be encouraged to take the time to understand the flaws in their thinking and if they simply file a graded assignment into their notebooks without taking the time to seriously look at it, then no real learning is taking place. Students are provided a grading rubric in the course syllabus and they understand that as long as they complete the assignment according to the prescribed directions, they will receive full credit. The purpose of this grading scheme is to encourage students to think deeply about the comments they have received and then do whatever they need to do to correct any problems with their thinking and understanding of a particular topic or concept. Thus, the folder activities give students an opportunity to learn from their mistakes without risk of penalty. Students are very comfortable with this grading scheme, and genuinely enjoy receiving the written feedback provided on their folder assignments. In fact, students often times bring their folder assignments in during office hours once they have received the written feedback in order to address the flaws that might have existed in their thinking.

Approach (2): Interactive Online Chats Using Blackboard Technologies

The second teaching approach used with introductory physics students involves the use of live, interactive online chats using Blackboard technologies. This approach was piloted during the fall 2002 semester. The *Blackboard Learning System*™ [36] is a technology platform aimed at achieving several objectives including:

1) Measuring and improving student performance.
2) Increasing instructor productivity.
3) Enabling "Web-enhanced" classroom-based teaching and learning.
4) Delivering distance learning.
5) Supporting lifelong continuing education.
6) Blending the benefits of face-to-face and online learning through the use of hybrid courses.
7) Leveraging technology to enhance institutional competitiveness, applicant selectivity and retention.
8) Providing a platform framework that integrates course and learning management capabilities with an organization's student information, security, and authentication protocols.

9) Providing a framework for managing an institution's digital assets and content. (p. 3)

The *Blackboard Learning System*™ also features an online environment that has been designed to supplement either traditional learning or distance learning. Through an intuitive interface, instructors are able to manage online environments for teaching and learning by using the following utilities:

1) Content Management and Content Sharing.
2) Assessment Management.
3) Gradebook.
4) Collaboration and Communication.
5) Assignment and Portfolio Management. (p. 4)

Blackboard Inc. recently announced the charter release of the *Blackboard Learning System ML*™ in Brazilian Portuguese [37] in October 2002. The *Blackboard Learning System ML*™ is a multi-language edition of the company's market-leading course management system. Other languages available through this system include Chinese, French, German, Japanese, Spanish, and English. In addition, others including Dutch, Italian, and Korean are currently being developed. Thus, the global nature of this learning environment has broad ranging potential for use at the international level.

The particular feature to be explored in this paper involves the collaboration and communication utility of Blackboard. During the fall 2002 semester all students in PMW were enrolled in a course-specific Blackboard site. Students had immediate access to course documents such as syllabi and assignments. The instructor was able to communicate with all students by email through the Blackboard site to send reminders, announcements, etc. In addition, the Blackboard site provided a forum for interactive online chats. The chats are similar in nature to AOL *Instant Messenger*™ (AIM) [38] that is so commonly used by students to chat with their friends on the web. With AIM the chats with friends appear on separate screens. Thus, if a student is chatting with several friends simultaneously, the desktop contains a screen for each person they are chatting with. The unique feature of Blackboard is that the instructor and students can chat on a single screen. This feature allows for a continuous discussion to take place between everyone logged into the chat.

The online chats provide a useful way of allowing for peer-, rather than instructor-given feedback. In addition, online chats allow students to use a different form of writing to communicate with their peers. The online chats have also proven to help students elicit and confront their misconceptions [39]. The most common use of the chats has been for the discussion of homework questions. During the semester, chats were routinely scheduled for days that coincided with when homework assignments were due. The chats were set up on different days and at different times each week so as to allow more students an opportunity to participate. The chats were not required, but rather they were advertised as an additional way for students to get assistance on their homework when they needed it. One feature of Blackboard allows the instructor to prohibit anonymous postings. Thus, each chat participant was recognized by name. During the chats students would often refer to each other by first name. This recognition created a very professional working environment for the online chats.

The format of the chats consisted of a student(s) posting a specific question to the group. Other members of the class were then free to jump in and offer the student help and advice. If the students fell off course with their discussion, the instructor would offer some guidance and attempt to steer the discussion back on track. Oftentimes the instructor would make use of Socratic dialogue techniques during the chats. Hake [40] developed the Socratic Dialogue Inducing (SDI) lab method which combines interactive engagement teaching and learning strategies with various forms of hands-on experiences. The SDI method was the outgrowth of the work of Arons [41]. Much of Arons work stemmed from the work of cognitive science and often blended ideas from scholars such as Socrates, Plato, Dewey, and Piaget. SDI labs have proven to be an effective way to guide students to a more solid conceptual understanding of Newtonian Mechanics [42]. Hake has suggested that the SDI method might be characterized as "guided construction" rather than "guided discovery" or "inquiry". Through the online chats the instructor encouraged guided construction by posing frequent, probing questions to the students. The instructor also used the chats to facilitate a "think out loud" protocol in which both the students and the instructor could offer assistance and guidance to a particular student's question or comment. This strategy appears to be a very effective way to assist students in confronting their personal misconceptions about a particular topic or concept.

Typically about 20 students would log into the online chats. This represents approximately 15 – 20 % of the total number of students enrolled in the PMW class. However, this number is potentially misleading as many more students took advantage of the discussions generated during the chats. A unique feature of the Blackboard chats is that they are automatically archived online. This means that a student who is unable or chooses not to log in and participate in the live chat, can access the archives at any time. Through informal discussions with students the instructor determined that a much larger percentage of students were actually taking the time to look at the archives prior to completing their homework assignments. As a result, the quality of the homework papers submitted by many students during the semester was very high in comparison with previous semesters.

The use of online chats offers a relatively new avenue through which the learner can take an active role in the learning process. Furthermore, the online chats can be viewed as one form of computer-assisted communication that promotes interactive engagement of the learner with the content being studied. In addition, the online chats may offer some students a more "comfortable" environment in which to interact than the traditional large lecture class. Although students are identified by name during the chats, the instructor works to be sure that each student is treated with respect. Students were very comfortable with the fact that their comments could be identified by name and never expressed any discomfort with this concept.

Certainly there are advantages as well as disadvantages associated with any form of computer-mediated instruction. This mode of communication has the potential to offer greater consistency and to enable students to improve their communication skills while engaging in problem-solving activities [43]. In addition, key differences between computer-mediated conversations and face-to-face discussions include: place dependence, time dependence, and structure and richness of communication [44]. However, if used as an additional learning tool, the online chats can offer students an alternative to traditional instruction and simultaneously appeal to a wider diversity of learning styles [45]. In the section that follows, a brief synopsis of student perceptions regarding the two instructional approaches described is presented.

STUDENT PERCEPTIONS OF THE LEARNING APPROACHES

Student perceptions regarding the two learning approaches highlighted in this paper were elicited through classroom surveys as well as through informal communication between instructor and students. A summary of the results of several surveys regarding the folder activities given in recent semesters will be presented. These results will be shared in the form of typical student responses. Given that the Blackboard chats were first used in the fall 2002 semester a survey was not conducted. Thus, a summary of student feedback elicited through informal discussions will be shared. In future semesters, additional forms of assessment of student perceptions as well as of student learning will be employed.

Regarding the folder activity, students were asked whether or not they found that the written feedback they received had encouraged them to think more deeply about the physics concepts discussed in class. Some common student responses were:

- "It made me think more about the common sense behind the physics."
- "With the amount of writing on the paper and the fact that I knew you took the time to look at my work I knew that I needed to spend more time on my physics, but not necessarily a specific concept."
- "The feedback makes me think more deeply about what I have written. The feedback on the **learning style** made me think more than the second one [folder assignment]."

In terms of the online chats, many students acknowledged that even if they could not log into the live chats, they did make use of the archives when they were completing a homework assignment. Several students indicated that the live chats as well as the archived discussions were so useful that participating was a "no-brainer!" In some cases, students would request a chat, which indicates that they genuinely found them valuable to the learning process.

Overall, the results of these surveys and informal discussions suggest that students found the writing and online chats beneficial and useful to them in some way. A fundamental difference between each of these learning approaches involves the nature of the feedback students receive. With the writing activities, students receive feedback directly from the instructor. However, with the online chats feedback is predominantly from students' peers. These approaches, albeit quite different, provide students with diverse learning styles some additional learning tools and strategies.

CONCLUSIONS

Acknowledgement of students' individual learning styles can play a critical role in the learning process. Furthermore, the use of formal learning style assessments can provide useful information that benefits the student as well as the instructor. Important to note is the fact that the learning style assessment tool used is not as critical as the actual assessment of learning styles. Through the specific teaching and learning strategies that have been described in this paper, the value and importance of adopting a learning style approach in the classroom has been illustrated. It is the contention of the author that the adoption of a learning style approach in the classroom can increase student interest and motivation to learn, in part, through the development of alternative learning strategies designed to accommodate an increasingly diverse population of learners.

AN EXPERT SYSTEM OF THE ESTIMATE TECHNOLOGY FOR DISPLAY MEANS

Park, Sang-bong[1]

Abstract — *An estimate technology for standard machining time focused on the large size TV set has been studied. Generally speaking, the estimate calculating work of mould is achieved by experienced engineers. However, at most mould manufacturing enterprises, there are frequent cases that they calculate by rule of thumb because they have neither established standardization nor have determined clear estimate method. As the result, in fact, it is natural that not only much time is wasted but also absolutely draw up and submit non-consistent quotation, which leads to raise major and minor quarrels with their clients continuously. Therefore, in order to remove such a problem point, in this study, the development and application of expert system is studied for estimate calculation at the mould manufacturing process. The application of the developed system to the working site has the advantage that even beginners can create better quoting result than experts. The developed system used visual BASIC language and SQL Data Base under Windows environment.*

Index Terms — *Estimate technology, Expert system, Machining time, Mould base, NC data*

INTRODUCTION

The mould technology has been developing pretty rapidly as well as being in good harmony with the technical renovation of the 6T. And, this trend is expected to continue at an increasing tempo, while deepening the width and depth of its application even more. The rapid economical and social transition in recent years have changed the technologies of production and cost management in manufacturing sector remarkably. In particular, the mould manufacturing sector requires innovative changes in quality, cost and delivery and, accordingly, the improvements in technical development, productivity and reliability are on the way to meet the requirements. Also, the trade volume of moulds are increasing continuously and the various restrictions on international trading are strengthening more than ever before.

The countermeasure of the mould enterprises in this circumstance, unlike what had been in the past, is to submit more rational, rapid and objective data, and only a settlement of management technology, say of one stage more advanced, will enable enterprises to survive and develop steadily in the future. However, still now most of enterprises follow neither objective nor scientific estimate method and are still facing with occurrence of frequent and indefinite claims from their clients. So they are suffering great damage in judgment of right or wrong.

In spite of an importance of the scope there has been very few relevant reported works in literature. In particular, Olsen[1] analyzed the prime cost for magnesium die casting mould in 1988, and Rosen et al.[2] studied and presented the prime tool cost for injection mould and die casting in 1992. On other hand, some large enterprises have developed their own system for mould prime cost calculation. However it usually can be applied only to some specific conditions. Clearly that the variety of real situation and need at many enterprises requires general but much more sufficient approach and development.

In order to remove such a problem, this study aims to build up an expert system in order to handle mould for display means. The built up system consists of Ini-MOULD 2002™ for initial estimate calculation.

STANDARD PROCESSING TIME FOR MOULD MANUFACTURING

Standard Processing Time

Based on researches so far, the standard process time in mould manufacturing can be measured by the Time Study Method, Pre-determined Time Standard Method and Standard Data Method, etc. Figure 1 is showing the content of mould processing time by disintegrating its structural elements.

- **Preparatory time, Setting time:** It includes time for preparing clearance and spare time for preparing as necessary preparing and clearing for machine processing occurred only one time for specific manufacturing quantity (1 processing lot) of the same processed good. Much time for thinking how to work is included in the preparing work. Generally speaking, we don't separate time for clearing from the time to spare in considering the preparation time. From the mould processing stage to the stage of finishing preparation requires some time for test processing.

[1] Park, Sang-bong, Dongeui Institute of Technology, San 72 Yangjung-dong, Busanjin-gu, Busan, 614-715, Korea, psb@dit.ac.kr

- **Cycle time:** The time necessary for mould processing for a unit of processed good includes the real repeat time (the real processing time and the real supply demand time) and the time to spare.
- **Net cycle time:** The repeat clearing time includes the machine time (real processing time) of automatic transfer and manual transfer, and the supply demand time (real supply demand time) accompanied to the mould processing. The necessary clearing time for cutting after the machine is operated includes the time for removing cutting chips or the time for air cut, when the cutting chips are not discharged due to approach to tools and over run. In the case of the NC machine, it is the length of time for tools to approach the processed goods from the machine origin to return the original location after finishing the necessary cutting.
- **Net handling time:** As doing mould processing for a unit of the processed good, it's the worker's working hour, such as installation and removal of the processed goods, maneuvering of machines and measuring of the processed goods, occurred incidentally.
- **Automatic feeding time:** It's the real processing time in the case that the mould processing is implemented through automatic transfer or numerical control.
- **Allowance time:** As a factor occurred irregularly during the repeated work, it's the length of time considered as time to spare since the insert is difficult during the real repeat time. The allowance time is calculated by multiplying the values required man hourly and materially in the type of percentage by the real time. The spare man hour means the fatigue spare to compensate the damage appeared due to the fatigue during work, and the physiological spare, such as going to the lavatory and drinking water, etc. The material margin means the so-called work margin, such as the irregular and various time to spare occurred materially from machines, tools and materials, etc.

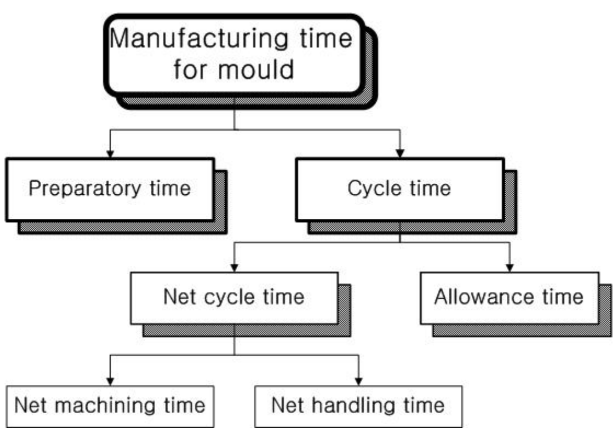

FIGURE. 1
CLASSIFICATIONS OF MANUFACTURING TIME FOR MOULD.

There is a work place margin to compensate the time to spare occurred due to the managerial irrationality during work. It is not related with mould processing, and divided by the non-processing time.

CONSIDERATION OF THE MOULD FOR DISPLAY MEANS

In the case of TV products, we are going to examine in this study, are moulds composed of big mould base, having 1 cavity. The mould base can not use the standard type. A TV mould part can be largely divided by two parts, front and back. We are going to research on the front and the back.

FIGURE. 2
FRONT PART OF TV PRODUCT.

FIGURE. 3
BACK PART OF TV PRODUCT.

Figure 2 shows the front part. The front is characterized by the precise small electrical discharge machining to accommodate speaker holes in the front side and the installation of the bottom side core for installing a control knob in the bottom side.

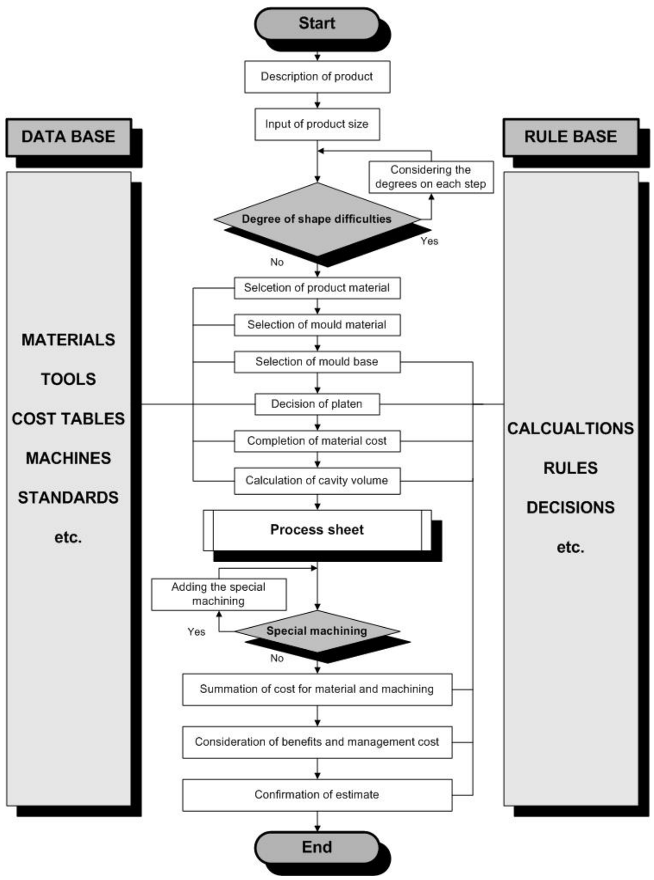

FIGURE. 4
MAIN STRUCTURE OF SYSTEM.

Figure 3 shows the back components. The pivotal point is to calculate the processing time for machining a lot of holes for air vent on the back side and for the milling machining to make deep cavities. Also, a lot of electrical discharge machining is required to form the bosses and the ribs. The calculating technology for the standard processing time of mould manufacturing is needed by both sides of placing and receiving orders at the same time. The order placing side can utilize it for suggesting standards and the order receiving side can utilize the system for producing quotations, considering the company's working load. The suggested amount can be modified through verification and coordination, and the final quotation can be decided objectively.

Figure 4 shows the organization of the developed system. The input data for the system includes the general specification, size, materials and mould base type, etc. The material cost and processing cost are calculated based on those things. The mould base can be selected by deciding the weight of mould base and the size of the stationary and movable platen. The decision on the cost for hot runner and other mould factors is made in this stage. The processing cost is divided by the general processing cost and the special processing cost. The general processing cost means the cost for each process, from design to test, required to make a mould. We have established a system to calculate the processing time for the pertinent processing factor by inputting specific processing parts and shapes for the contents that are included in special processing cost like polishing, carving, core machining, corrosion and electrical discharge machining, etc.

The output unit calculate the mould manufacturing cost considering profits and general expenditures, and the processing cost, standard manhour rate and standard processing time for each process are printed on specific forms. The system is designed to store the results into the database for future reference in preparing quotations for the similar products and for the records management.

Process Sheet

The previous study[3] calculates all factors of moulds by repeating the degree of shape difficulty, and then the standard processing time for special processing is calculated by considering the necessity of special processing. In this case, we were able to get the adequate result if the mould is based on the standard mould base or the mould assembled by the standard mould factors.

AN EXPERIMENTAL CREATIVITY RESEARCH IN DESIGN EDUCATION BY HIERARCHICAL APPROACH

Elmira Sener[1], *Secil Satir*[2]

Abstract — *Design education is an area which has a broad point of view in its context. It consists of the feelings, thoughts and conception of both the designers and the users. Design students are confronted with some design problems in order to gain general continuity of creativity and ability. In some cases, these problems are based on some theoretical thought but they can also be formed with various materials, geometric shapes and objects exemplified in environment.*

The main subject of this paper is the experimental studies conducted by grouping student according to their classrooms in design education. Consequently, only creative structures based on figure is received from the least-educated students. At the same time, knowledge-base structures were increased as the education level increased. Maintaining original compositional structures was a result based on knowledge and experience. According to the conclusions, the study states that design education should be a motivator, not a demander even in a knowledge-providing phase of the education process.

Index Terms — *Design, design education, design students, design process, creativity.*

INTRODUCTION

Designing is an area and a notion which has creativity in its essence which is combined with the concept of creation. To design means to create in the mind and to find solutions. Basically, almost all the problems of architecture, industrial design, engineering or the daily life, reach the first step of the solution process by the formation of the creative ideas in mind.

Designing is a process in which creativity constantly appears. This process is formed in the mind while being reflected outside as a behavior or an act. The designing or the creation process of designing which happens in mind, is generated as a new knowledge by combining the knowledge base formed from the necessary past experiences and the information sets of a given problem. According to this, creativity is not a notion which was present before (a priori) but an ability that is developed through time. Because, the formation of a synthesis is impossible without the presence of similar perceptions in mind [1].

In our time, it is understood that creativity that is known as the flexible feature of the mind about sensibility can be improved. If the course of the improvement of the creativity is initiated from the early ages and appropriate setting is defined, successful results can be obtained. Feldman (1999) has studied the dimensions, which affect the development of the creativity during individual development. In this context, the subjects that affect the creativity during individual's growth are the family structure, formal and informal education, social and environmental specifications, social-sensitive proceedings, cultural and historical effects, variables dependent to situations, inclinations [2].

The process of the improvement of the level of creativity of the design students in the level of higher education is initiated with the "Basic design" course in almost all of the design schools. All the design problems both in the scope of the basic design course and the projects, which are done in other science and art courses, are specifically designed to prepare the students for their professional lives.

CREATIVITY IN THE DESIGN EDUCATION

Design education is a kind of process, which makes a synthesis of science, technology and art fields, which generally have a wide point of view, according to their importance. Design education in which both theory and application are delivered together, includes the human thinking, sensitivity and perceptions about creativity all together.

According to Cooper and Press, design education should aim to be involved in creativity process as an inseparable part of creative thinking. The ability, knowledge and perceptions of the students differentiate from each other. Throughout the education, the evaluation of these components in order to improve the creativity is very important [3].

The basis of the design education is constructed specifically to improve the creativity of the first year students. Experimental and introductory design and design project courses in which students communicate directly with materials, get familiar with the potential of the material and combine with their creativity; teaches the student to make their thinking systems more flexible and helps them to form solutions for the problems.

An important problem about the professional practices of all the students is their difficulties in putting creative ideas together and their ignorance about what kind of a strategy they can follow.

AN "EXPERIMENTAL CREATIVITY" STUDY IN DESIGN EDUCATION BY HIERARCHICAL APPROACH

An experiment has been conducted for seven hours in a rectangular area of 900 m² in order to emphasize the creativity in design education and to test the necessity of giving a quality of basic course in each class. This experiment is conducted with 70 architecture and industrial design students.

Although this creativity experiment has been planned to be conducted with 25 volunteer students, because of the reduction of the number of students in the list, it is directed with 20 first year, 17 second year, 13 third year and 20 fourth year students. Some materials and questions were given to students and they were differentiated according to the levels of experiment groups.

Students were divided into four groups according to their classes. The materials given to the groups were simple ones like, wood sticks, wood pieces in geometric forms, matches, plasterin, string, textured aluminum pieces, cardboard, colored pieces of paper, pasta, egg, craft paper, synthetic wires, synthetic fiber board, synthetic pipe covered with folio.

An explanation was made to experiment groups about the experiment subject before the distribution of the materials. A pre-explanation were performed with a slide show about creativity, how it is formed in thinking process, how does knowledge and perceptions can effect the creative thinking and how does it feed the allusions of the thinking system .

After such an explanation, in the study in which everyone was asked to work individually, 2 hours were given for each question and at the end, three creative design applications were maintained. In addition to this, they have been asked to determine ten concepts about each application. The materials and design subjects given to first and the third year students were the same and similarly they were the same for the second and fourth year students.

It was not possible for students to watch or to look at each other because the experiment took place in different parts of a long studio, and in a short amount of time.

Evaluation of the Experimental Creativity Study

Criterias on the evaluation of the studies were,

- Students' general level,
- The concepts they chose,
- The structural appropriateness in terms of basic structure concepts such as weight, force and balance,
  - Harmony with the material,
  - Appropriateness to the structure of esthetical rules: balance, rhythm, proportion,
  - Structural construction
- Reflection of creativity on the design,
- Its ability to combine knowledge and creativity.

Evaluation of the First Year Students

First year students had worked on three different design questions with the designs made of given materials such as wood sticks, wood pieces, matches, plasterin, cardboard, an egg, strings and wires, craft paper, synthetic wires, synthetic fiber board and pieces of aluminum. In addition to that, 10% students had interpreted the part "a" of the first question, which was asked also to others, as the preparation phase of the "b" part. %90 of them had done according to the concepts.

Hundreds of concepts were emerged like, "difference, ordinariness, contrast, elevation, excitement, chaos, unity, life, balance, sharpness, emptiness, solidarity, helplessness, summit, permeable, crater, danger, etc. Like all the other students, the first year students determined in 10 concepts for each of three questions and produced designs evaluating these designs. 90% of the student designs were in harmony with the concepts.

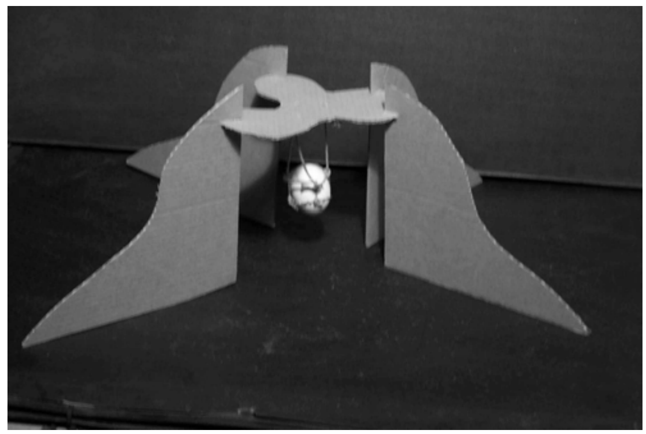

FIGURE-1 A SAMPLE OF FIRST YEAR STUDENTS' DESIGN

When the structural construction of the material was in question, the proportion of encouragement of the light structured buildings was low. When it was asked to carry the egg 15 cm above the ground, cardboards were usually folded in various sides in order to produce structural constructions. Because of the lack of knowledge of structure, determination of maintaining security was stressed.

FIGURE-2 A SAMPLE OF FIRST YEAR STUDENTS' DESIGN

Apart from this, conclusions of the study which were produced with little knowledge and which could be attained only through the textures of the material were in lack of creative, flexible sensitivity.

Evaluation of the Second Year Students

The common materials that the second and fourth grade students used were pasta, strings, cardboard, wires, colorful pieces of paper, synthetic strings, wood sticks and a synthetic pipe covered with folio. In the second year, %85 of all the three questions were done. The 15% was in excess because some of the students combined the "a" and "b" part of the question.

Again, designs were prepared in accordance with the ten concepts chosen for each question such as, "expectation, privacy, curiosity, symmetry, rhythm, eternity, courage, solidarity, dialectics, balance, focusing, explosion, beginning-end, firmness, energy, multiplication, emptiness, trustworthiness, horizontal-vertical, music, motion, protection, shield, fullness, unity, contrast, space, transformation, asymmetry, axe, fluidity, pass through".

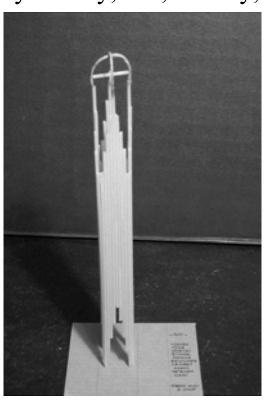

FIGURE-3 A SAMPLE OF SECOND YEAR STUDENTS' DESIGN

Although their concepts of solutions were in harmony with their designs, it was realized that second year students were able to evaluate their creativity in terms of establishing links between the problems by 50 %.

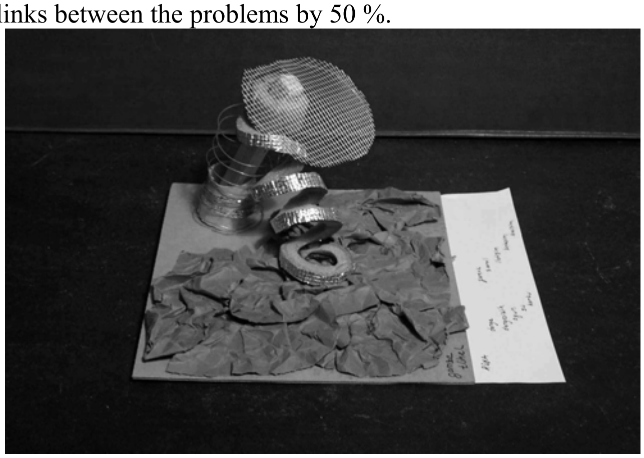

FIGURE-4 A SAMPLE OF SECOND YEAR STUDENTS' DESIGN

88% of them preferred to use color. In the concepts they chose, a kind of order was realized which was emerged from the their own knowledge of rhythm, symmetry, balance, energy, fullness, contrast, etc. In 87% of the designs, the consciousness about space, order and geometrical knowledge was observed. 13% of the students designed really complex designs.

Evaluation of the Third Year Students

The participation of this group was very low. Only 13 of the invited students had participated to the workshop. Yet, designs produced were sufficient to demonstrate the improvement of creativity between the classes.

The questions and the materials given were the same with the first year students. In those designs the concepts were different than the previous ones. They were cooler and more "frozen" such as "elevation, sign, direction, bayonet, fewness, grief, shadow, motion, nothingness, umbrella, system, logo, linkage, guitar, chaos, frontier, tying, inner, hardness, continuity, division, differentiation, individual life, section-whole, geometry, messy, complex, ugly, ordinary, artificial, permeable, bird nest, labyrinth, hard work, craziness, shadow, lost, time, speed, illogical, cry".

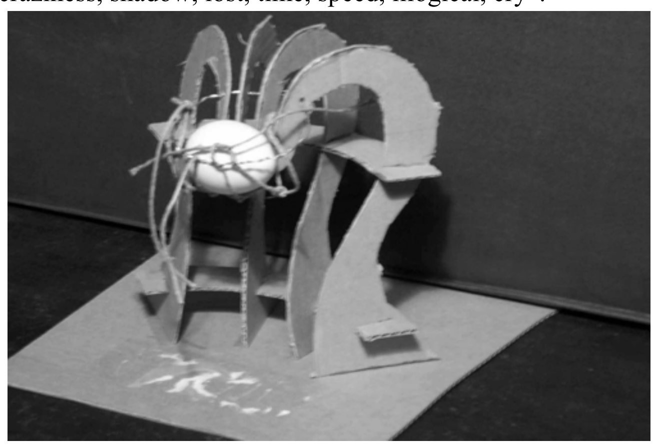

FIGURE-5 A SAMPLE OF THIRD YEAR STUDENTS' DESIGN

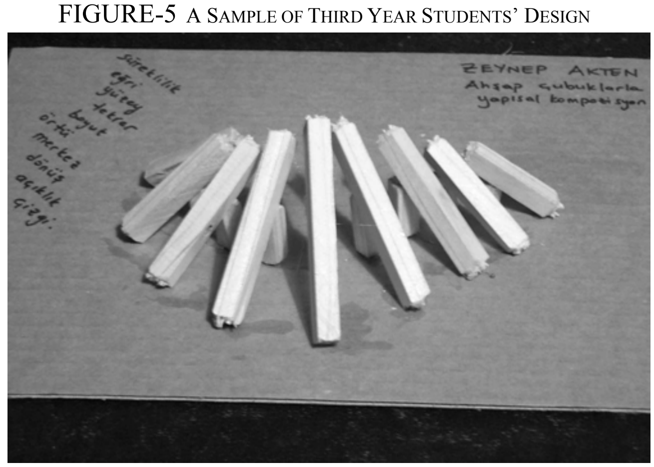

FIGURE-6 A SAMPLE OF THIRD YEAR STUDENTS' DESIGN

Designs were, again in harmony with the concepts. Throughout the concepts of the third year students, it was realized that the positive concepts were quite a few. Designs were observed to be created directly by analogies by using meaningless and negative concepts by 50%.

In the second question, 18% of the students hadn't completed their tasks and in the last questions, they changed their materials and started to use other groups' materials.

Evaluation of the Forth Year Students

Participation rate of the fourth grade students was high like the first year students. The materials given were the same as the second year students. 50% of them had not differentiated between the "a" and "b" part of the question and answered both of them with the same design.

The concepts they used were extremely structural and esthetical concepts like "emptiness-fullness, tearing, rhythm, balance, order, wave, knot, holding, valve, to approach, to go away, support, emptiness, folding, stretched, to direct, to stretch, horizontal, vertical, underground, above the ground, open-closed, spatialization, back bone, trust, arcade, bump, direct, triangle, energy, sails, roads, to hold, dreaming about thinking, willing to think, orthogonal, superposition, coordinate". The high participation rate showed that the students were aware of their design consciousness and they were willing to learn more. They preferred to use these materials to organize concepts like rhythm, balance, and proportion.

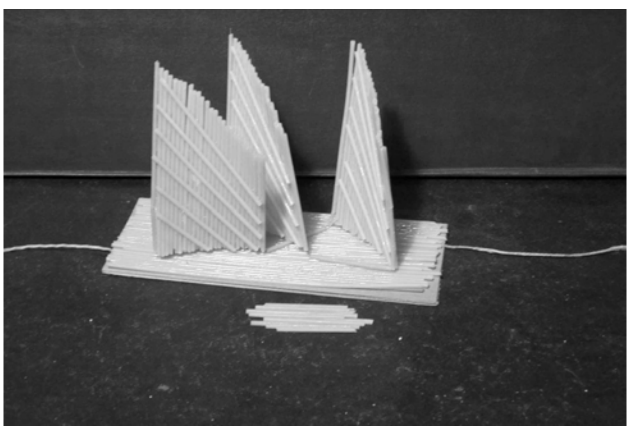

FIGURE-7 A SAMPLE OF FIRST YEAR STUDENTS' DESIGN

55% of this group worked neatly and completed their designs. Apart from them, 65% of the students managed their designs mainly with knowledge-base concepts.

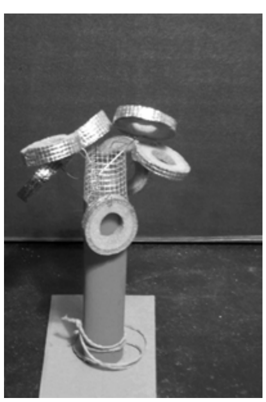

FIGURE-8 A SAMPLE OF FIRST YEAR STUDENTS' DESIGN

Fourth year students were more inclined to use the material more freely. Shiny, cylindrical isolation material was commonly used both by the fourth and the second year students. 79% of the fourth year students specifically used this material.

GENERAL EVALUATION

This experimental study about the need of creativity education in the programs of all the years cannot be expected to give 100% true conclusions. To provide more accurate conclusions this experiment is needed to be repeated over and over for some years. Additionally, the backgrounds of each student, their capabilities, and way of living and growing up will also affect the research.

However, many students had participated to a weekend workshop without any obligations. Although they were not over a hundred people, the enthusiasm of the curious students who were aware of the importance and the meaning of design constituted a firm base for this evaluation.

The high participation rate of the first year students was because of curiosity whereas the fourth years' was because of consciousness.

In all levels, the chosen concepts and the designs were in harmony. Some designs are differentiated according to different levels of construction, structural and esthetical knowledge.

CONCLUSION

We think that design courses should be given not only in the first years as a basic design education, but in all years in the context of design projects or creativity courses. These courses should be supported by structural concepts.

The structural knowledge which fourth year students observed to have, should not be constructed as partially learned knowledge in design studios. They should be thought in creativity courses from the first year until the fourth year where structural concepts and philosophical concepts will support the imagination. The imagination and thinking capacities of the students should be enriched with the design made from different materials and compositions.

LABORATORY PROGRAMS ON PHYSICS WITH USAGE OF MODERN INFORMATION TECHNOLOGIES

Konstantin A Ekimov[1], Roman V Prichodchenko[2], Anatoly D. Khakhaev[3].

Abstract *— A set of laboratory programs used in education courses of atomic and quantum physics, metrology, spectroscopy and plasma diagnostics has been presented. The training is performed with use of new information technologies and a possibility of remote access to the equipment. Students come to know a subject area (e.g. determination of fundamental atomic constants, Zeeman effect, plasma diagnostics, temperature determination, eliminating the apparatus distortions etc.) in parallel with acquiring habits in usage of modern information systems and effective methods of accumulation, processing and transformation of data. They are trained in usage of local and remote information resources and study the operation principles and possibilities of various measurement sensors. Such an approach promotes both a knowledge basis in the subject under study and formation of a specialist, who is ready to work in the modern information environment.*

Index Terms — Atomic physics, information technologies laboratory program, remote access, spectroscopy, virtual instruments.

INTRODUCTION

In the Department of Information- measuring Systems and Physical Electronics of Petrozavodsk State University laboratory programs on the following courses: Quantum and Atomic physics, Metrology, Optical methods of plasma diagnostics are carried out with usage of new information technologies: virtual instruments and opportunity of the removed access to the equipment. The virtual instruments is essentially an information- measuring system, with the interface which is similar to the panel of the usual device and has been created in graphic programming environment (for example, LabView) Thus, simultaneously with studying problems of a subject area (for example, Zeeman effect, plasma diagnostics, temperature determination, eliminating the instrument distortions etc.), our students gain experience in application of modern effective data acquisition and processing methods.

They are trained in usage of local and remote information resources, get acquainted with a principle of action and opportunities of various measuring sensors.

Alongside with fastening of knowledge in an investigated subject, such laboratory programs form the expert ready to work in the modern information environment. The brief description of our typical installations and laboratory programs are given below.

LABORATORY PROGRAMS CARRIED OUT ON AUTOMATED SPECTROSCOPIC SET UP "LIGHT"

The set up is destined for local spectroscopy of inhomogeneous and non-stationary plasma. It allows to carry out spectrum scanning by large aperture diffraction spectrometer with resolution 0.015nm in the range 300-800 nm, scanning of spatial source surface radiance distribution by special spatial scanning block and to choose for radiation measurement the certain time moments, if a source characteristics are periodically varying . Experiment control is based on Labview and instrument interfaces, compatible with this system. The system runs under the control of the IBM-compatible computer with OS Windows-98.

The software includes the following functional modules:

a) Module of spectral device calibration on wave lengths by a source with a known spectrum ("Spectrum calibration").

b) Module of the photodetector sensitivity calibration by the registration of a certificated temperature lamp spectrum. ("Sensitivity calibration").

c) Module of spectrum scanning in the given spectral range with the given step ("Spectrum scanning").

d) Module of spatial gating at a given wave length ("Spatial scanning").

e) Module automated spatially and spectral scanning in the given spectral and spatial intervals and time phase ("Spectrum -spatial scanning").

f) Module of data loading for subsequent analysis ("Spectrum load/Analysis").

g) Module of the remote access server.

[2] Roman Prichodchenko, Petrozavodsk State University, Department of IMS&PhE, rvprihod@st.karelia.ru
[3] Anatoly Khakhaev, Prof, Dr, Petrozavodsk State University, Department of IMS&PhE, alim@karelia.ru
The research described in this publication was made possible in part by Award No. PZ-013-02 of the U.S. Civilian Research & Development Foundation for the Independent States of the Former Soviet Union (CRDF) and of Ministry of Education of Russian Federation.

Each module is made as a "virtual instrument", on the panel of which there are windows for input of the necessary information, control buttons (start of the module, save file) and graphic field for result representation. The example of such panel is given in Figure 1.

The module "f" allows to transform automatically the digital reading array to array of a source surface radiance, if earlier calibration by the module "b" was executed, and also to derive various information from a spectrum (e.g. maximum positions and values, line widths) by Labview tools for graphic processing (scaling and cursor positioning).

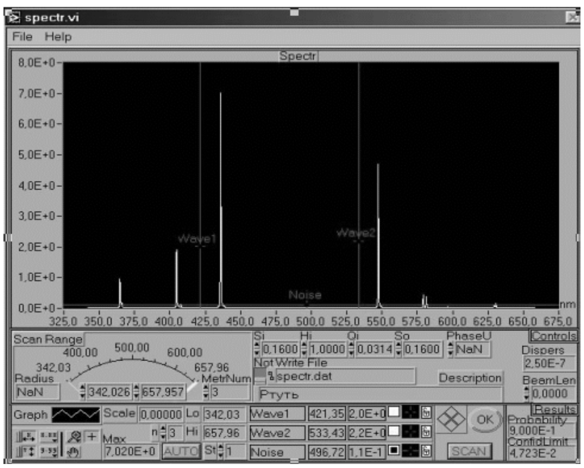

FIGURE. 1
VIRTUAL INSTRUMENT " SPECTRUM SCANNING".

The module "g" provides an opportunity for the removed experiment control.

When a user saves data file, the information file is automatically created, where date of the experiment and all experiment conditions (spatial and spectral range, gating steps, spectrometer slit aperture parameters and so on) are written together with any additional information entered by the user (e.g. type of the source, discharge current, etc.).

On this set up the following laboratory programs are carried out:

Studying Serial Laws in the Hydrogen Spectrum and Rydberg's Constant Determination

This program is included in the course "Atomic and Quantum Physics "

In the simplified variant of work the student with the help of the module. " Spectrum scanning " registers a survey spectrum in a range 405- 660 nm. Then for more exact definition of waves lengths spectra in the interval of 5 nm from the found lines are registered with the minimal step.

For each measured wave length the wave number $\tilde{\nu}$ and Rydberg's constant R is determined by the formula:

$$\tilde{\nu} = R\,(1/4 - 1/n^2), \qquad (1)$$

It is supposed, that all registered lines belong to the Balmer's series. Taking into account, that wave lengths and line intensities in the Balmer's series decrease with growth of the main quantum number n, for a line with greatest wave length n=3. The received R values are averaged over all lines and then it is checked, whether the theoretical value ($R=109737.31\ cm^{-1}$) lies in 95 % confidence interval for R.

The complicated variant of work assumes preliminary spectrometer calibration on wave lengths by module "a" with use of cadmium spectral lamp.

Metrology Certification of Information Measuring System

This program is included in the course" Metrology".

The certification consists in an experimental establishment of correspondent of a system metrology characteristics to their values specified in the system documentation.

This program offers to execute operations on certification of set up "Light" as a tool for wave length measurement in the range 400-600 nm. The systematic error in a measurement of wave lengths should be no more than 0.1 nm, random - no more than 0.03 nm.

Using a source with a known spectrum (cadmium spectral lamp), in which the wave length values are known with the accuracy of 0.001 nm, and modules "Spectrum scanning" and "Spectrum load/Analysis", the student repeatedly determines the measured wave length values and calculates the random and systematic errors of the measurement.

By results of the experiment the standard " Protocol of metrology certification" has to be drawn up.

Determination of Temperature by Radiation

This program is also included in the course " Metrology". It reveals the concepts of radiance and color (spectral) temperature and methods of their measurement.

Having registered a spectrum of radiation of a filament lamp in a range 400-600 nm with help of the module "Spectrum scanning" and having transformed file of readings in file of values of spectral radiance B of a source surface by the module "Spectrum load/Analysis", the students determine source radiance temperature T for several wave lengths λ by the Planck's formula:

$$B(\lambda,T)=2hc^2\lambda^{-5}\{\exp[hc/(\lambda kT)]-1\}^{-1} \qquad (2)$$

Here h- Planck's constant, c - light velocity, k- Boltzmann's constant .

Spectral temperature of a source is determined from the slope of the graphic $Y=f(1/\lambda)$, received from (2) with the assumption, that it is possible to neglect 1 in comparison with exponent for the visible spectrum part and also that absorption coefficient Q of a light source material in some spectrum area does not depend upon the wave length. Then:

$$Y=a+ b*(1/\lambda),$$

where

$$Y=\ln B+5\ln\lambda,\ a=\ln(2hc^2)+\ln Q,\ b=-hc/kT \quad (3)$$

The least square method is used for calculation a and b; from b the spectral temperature is determined.

Emission Spectroscopy of Inhomogeneous Plasma

This program is included in the course " Optical methods of plasma diagnostics ".

The experiment consists in registration of visible intensity spatial distribution of the arc discharge in several spectral lines along the directions, perpendicular to discharge axis. After appropriate data processing the radial distribution of excited level densities in discharge should be received. For this purpose the following modules are used:

-"Spectrum scanning"- for the registration of a survey spectrum and choice lines for discharge diagnostics.

-"Spatial scanning"- for spatial gating of chosen lines radiation along a direction x, perpendicular to the axis of a source and optical axis of system. Previously spectrometer is precisely adjusted to a maximum line intensity by the module "Tuning", which is called from the module "Spatial scanning". The input and output spectrometer slits are extended enough to receive integrated over line profile intensity.

-"Spectrum load/Analysis" for transformation the file of readouts to the file of values of spectral radiance B.

For each line from a file of radiance B (x) one can find the line intensity J for a distance r from the source axis by radial transformation:[1]

$$J(r)=-\frac{1}{\pi}\int_{r}^{r_0}\frac{\frac{dB}{dx}rdr}{\sqrt{x^2-r^2}} \quad (4)$$

(r_0- radius of a source border).

The students are offered independently to choose and to realize in program the decision of the integral equation (4) and on found J to determine of appropriate excited level densities N, since

$$J=ANhc/\lambda \quad (5)$$

A - the transition probability may be found in a reference book. Having determined densities N_k of levels with various excitation energy $E_к$, the students should check up the validity of local thermodynamic equilibrium model [1] in the given plasma point. The model is correct , if the next condition is fulfilled for all levels:

$$N_i/N_k=g_i/g_k\cdot\exp[-(E_i-E_k)/k] \quad (6)$$

(g_i, g_k-the statistical weights of the appropriate levels).

Laboratory Programs carried out on Automated High Resolution Spectroscopic Set up "Spectrum "

The installation is intended for research of spectral line structures and shapes. The single line is picked out by the prism spectrometer or the interference filter, high resolution is achieved by the Fabry-Perot interferometer. The spectra registration is carried out with the help of virtual instruments based on LabView.

Two variants of installation might be possible:

The first one uses the Fabry-Perot in a scanning mode.

The interference rings are drawn on spectrometer input slit, which with a cross slit, established in front of it, forms a scanning diaphragm, allocating in the center of the interference picture. Behind the spectrometer output slit the photo-electric recording system is established. Spectrum scanning is carried out by pressure change in compression chamber , in which Fabry-Perot interferometer is placed. Photo-electric system signals are converted into digital form and remembered by the managing module through determined time intervals, given by the user. The module of data viewing and processing one can see in Figure 2 .

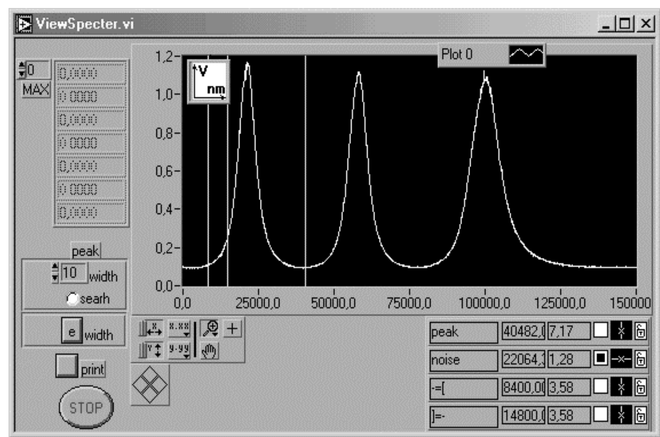

FIGURE. 2
THE RESULT OF SPECTRUM SCANNING BY FABRY-PEROT .

This module allows to save the results in a file, and also to analyse line shape and structure (e.g. maximum positions and values, line widths) by Labview tools for graphic processing

The second installation variant based on usage of a videocamera. Selection of spectral line is carried out by interference filter. The CD camera focused on infinity draws interference patterns on photodetector matrix . The panel of the virtual instruments for this experiment is shown in Figure 3. The module of data processing finds the center of rings and builds the dependence of interference pattern intensity on the distance from the center of a picture averaged over various directions. (Figure 4). The result can be printed out, saved in a file or processed directly by Labview graphic tools.

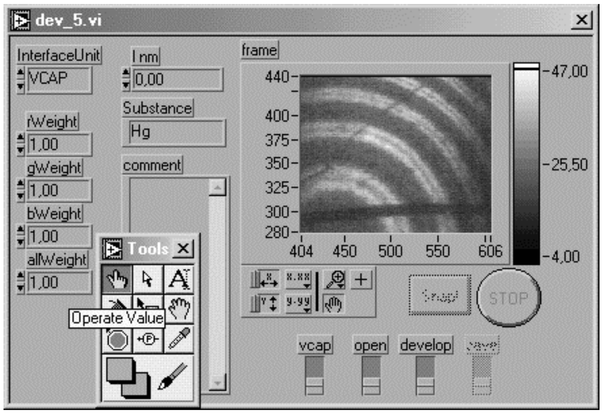

FIGURE. 3
VIRTUAL INSTRUMENT FOR CD CAMERA CONTROL.

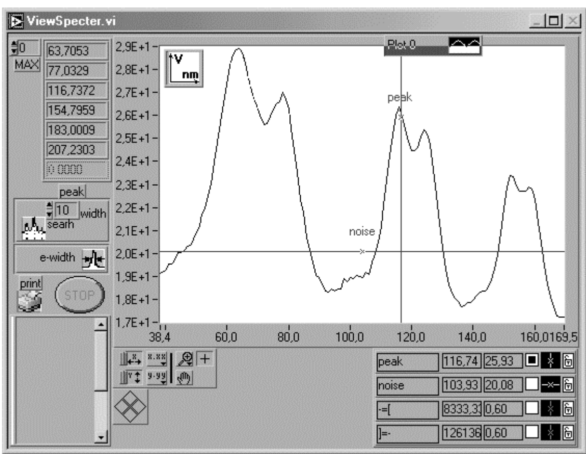

FIGURE. 4
VIRTUAL INSTRUMENT FOR ANALISIS CD CAMERA DATA .

On this set up the following laboratory programs are carried out:

Zeeman Effect

This program is included in the course " Atomic and Quantum Physics" .Spectral line splitting in permanent magnetic field is studied

The effect is observed on mercury lines of 579 and 546 nm, which are excited in a mercury discharge lamp placed between poles of permanent magnet. The analyzer of light polarization is placed between the light source and the Fabry-Perot interferometer.

By rotation of the analyzer one can see spectral line splitting components polarized along and perpendicular to magnetic field. Observation of the splitting and measurement of its value are possible in any of the described above variants of set up.

By the distance between the components, polarized perpendicularly to a field, of a line 579 nm, on which the simple Zeeman effect is observed, the magnetic field induction B_0 is estimated.

$$B_0 = \frac{hcx}{2\mu_B dX} \tag{7}$$

Here X-distance between nearby interference maximum in any units, x- the distance between components inside one maximum in the same units, d - interferometer thickness, μ_B-Bohr's magneton.

Measurement of Line Width and Determination of Plasma Atomic Temperature

This program is included in the course "Optical methods of plasma diagnostics ".

The light source is any low pressure discharge lamp.

The set up is used in the first variant. Some spectral lines are picked out by spectrometer and line shapes are received and saved in files.

In the assumption of absence of instrument distortions and Doppler line broadening mechanism [1] the atomic temperature T_a may be estimated from the line width $\Delta\lambda$.

.

$$\Delta\lambda = \frac{2\lambda_0}{c}\sqrt{\frac{2(\ln 2)kT_a}{M}}, \quad \Delta\lambda = \frac{\lambda_0^2}{2d} \tag{8}$$

Here λ_0- wave length of a profile center, M- atomic weight. This temperature will be obviously too high, since when working with Fabry-Perot interferometer, the instrument distortion, as a rule, could not be avoided. The interferometer spread function is:

$$P(\beta) = \frac{(1-R)^2}{(1-R)^2 + 4R\sin^2 \pi\beta} \tag{9}$$

Here β is the fraction of the distance between the nearby interference peaks (for each point x in the interference order β =x/X.) R- mirror reflectance. It is known. Students are offered to calculate the spread function and to eliminate the instrument distortion by free accessed program [2] . (Figure 5).

Having measured the width of the corrected line shape, it is possible to estimate atomic temperature in plasma more accurate.

The averaging over several lines gives even more reliable result.

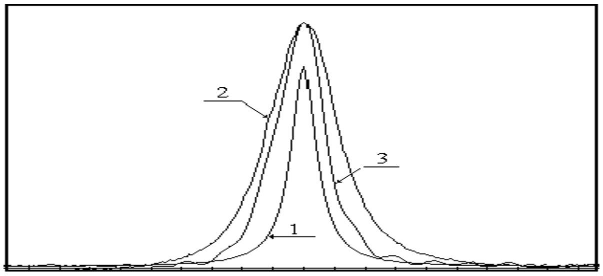

FIGURE. 5
THE PROFILE OF THE NEON SPECTRAL LINE BEFORE (2) AND AFTER (3) ELIMINATION OF INSTRUMENT DISTORTION .1- THE INTERFEROMETER SPREAD FUNCTION [2].

Having measured the width of the corrected line shape, it is possible to estimate atomic temperature in plasma more accurate. The averaging over several lines gives even more reliable result.

VERIFICATION OF THE ANALOG-DIGITAL CONVERTER (ADC)

This program is included in the course " Metrology".

The analog-digital converter is one of the main device of automated physical experiment instrument interface

The control of correspondence its metrology characteristics to required values is the necessary condition of experiment results reliability.

In this program the ADC, which is one of the CAMAC modules, have to be calibrated. The special driver allows to operate with CAMAC from LabView environment.

The precision voltage generator is used as voltage source. The student varies the test voltage according to randomized experiment plan and registers the ADC output by virtual instrument presented in Figure 6

The results are saved in a file for subsequent processing, which consists in estimation of the systematic and random errors of the device in all working range. As a result the conclusion should be made, whether this ADC metrology characteristics correspond to limits specified in the passport of the device.

REMOTE ACCESS OPPORTUNITIES.

All above described laboratory programs may be carried out with the remote access to apparatus. It is organized by LabVIEW tools on the basis of information interchange protocol TCP/IP.

Simultaneously with the experiment (e.g. spectrum scanning) the observation is possible with the help of the video-equipment with program support of videoconferences. Due to this technology, it is possible to observe visually and control the experimental process from another room (even from another country) if a computer is connected to a network and LabView "Remote access Client" is loaded.

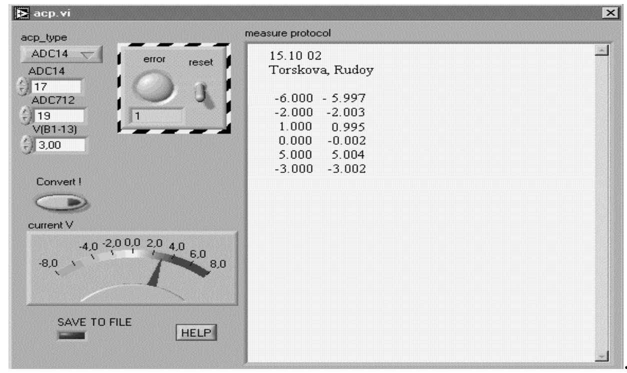

FIGURE. 6
VIRTUAL INSTRUMENT FOR ADC CALIBRATION TESTING .

This software is free accessed at http://194.85.172.228/index.html. Following the instruction the user can receive the list of laboratory programs. Having chosen the necessary program, the user will see the panel of the virtual instrument appropriate to the chosen experiment.

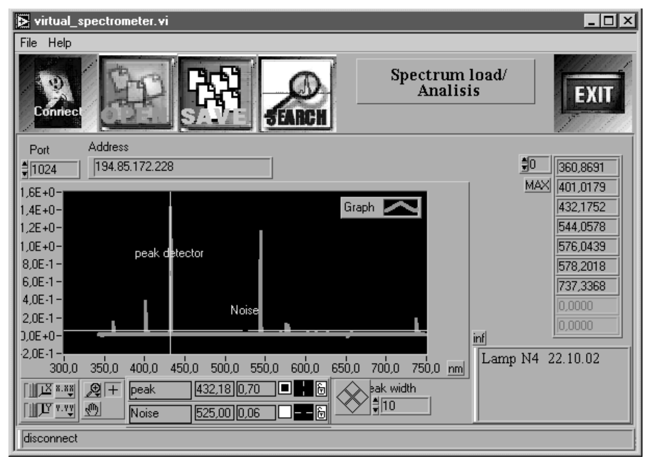

FIGURE. 7
VIRTUAL INSTRUMENT FOR REMOTE ACCESS TO THE EQUIPMENT. ONE OF THE SET UP "LIGHT" MODULE IS LOADED .

It is also possible to start the module of a videocamera control separately.

ACKNOWLEDGMENT

Authors wish to thank Professors L.A. Luisova, S.D. Wagner and E.I. Socolova for help and useful discussions.

FREE ACCESSIBLE WEB-BASED PROGRAMS "SIMULATION AND ELIMINATION OF INSTRUMENT DISTORTION" FOR EDUCATIONAL AND SCIENTIFIC APPLICATIONS

Alexei Soloviev[1] and Lidia Luizova [2]

Abstract — *In radioelectronics, image processing or spectroscopy one often cannot ignore the instrument distortions of data. If the instrument pulse response is known the reconstruction of input signal is possible, but the noises are significant obstacles on this way. Computer training programs for educational and scientific applications are described. The programs are designed for simulation of instrument distortions, elimination of those from simulated and real experimental functions, as well as demonstration of noise influence and opportunities of noise effect decreasing. The programs have been successfully used in courses on metrology, spectroscopy, plasma diagnostic, and image processing. One program, performing simulation and elimination of instrument distortion for one-dimensional functions, is executed on local workstation and requires Microsoft Windows 95/98/2000. The second one, destined for 2-D function processing, is implemented as web-service and only requires HTML 4.0 compatible browser. The programs and user's guide is accessible on web site dfe3300.karelia.ru.*

Index Terms — *computer program, Fourier transform, image processing, instrument distortions, noise, simulating experiment, training, web-based service.*

INTRODUCTION

Before computer engineering physicists solved complex problems approximately (for example, by means of processed function description with a few parameters, that is implicit a priory information about expected results). Calculating capabilities of computers cause the illusion of the absence of such information requirement. It seems a problem of any complexity could be solved if there is a principal solution, even it requires to solve 20-40 combined equations or reverse a matrix of 100x100 dimension. Although received results have no physical sense. Then mathematicians formulated the term "improperly posed problem" [1]. They called so the problems of obtaining information from experimental data when there is a strict unambiguous solution but this solution is highly sensible to experimental errors and even limited precision of calculation. So any variation of source data for a fraction of percent causes the result to vary for hundred times that is out of common sense.

The example of improperly posed problem is the elimination of instrument distortion. We deal with instrument distortion while performing dynamic measurement, i.e. when not a single value should be found but some function should (for example, the voltage as the function of time, the spectral intensity as a function of wave length etc).

Future engineers in optics, metrology, electronics, computer science have to understand the essence of this problem, to know how it may be solved and to see the limited nature of computing methods. The objective of this work is to develop computer programs for educational and scientific applications that allows:

- to simulate and graphically demonstrate the instrument distortions,
- to eliminate these distortions from simulated functions as well as from functions, received in real experiments,
- to demonstrate the influence of noise on the result of exclusion of instrument distortions,
- to show the opportunity of noise effect decrease by using a priory information and to demonstrate the limitations of this method.

These programs have an easy and clear interface and were successfully used in educational laboratories in courses on metrology, spectroscopy, plasma diagnostics, and image processing.

MATHEMATICAL BASIS

We consider only the instruments that could be described as invariant linear filters. Almost every design for dynamic measurement corresponds to this model in definite limits of input signals and usually one avoids to work outside of these limits. So the output function is the result of the convolution of the input signal with the instrument spread function.

$$f_{out}(\tau) = \int_{-\infty}^{+\infty} f_{in}(t) \cdot g(\tau - t) \cdot dt \qquad (1)$$

The instrument spread function *g(x)* (also known as *pulse response*, or *spread function*) characterizes the device

The research described in this publication was made possible in part by Award No. PZ-013-02 of the U.S. Civilian Research & Development Foundation for the Independent States of the Former Soviet Union (CRDF).

and corresponds to the output signal when the input signal is a single pulse or delta-like signal.

Of course, in real experiments the input and output coordinates are quite different, for example, wave length at the input and the element number of photodetective matrix at the output of spectrometer. But there is always correspondence between input and output coordinates that have been ascertained at the stage of graduation, so that we can use the same variable x for input and output coordinates. For simplicity, we consider one-dimension functions, but computation may be easy generalized to 2-D case of image processing.

The process of the elimination of these distortions and the reconstruction of true function is referred as "reduction to ideal instrument". We can lead this problem to solution of integral convolution equation (1). The well known way of solving this equation is using the convolution theorem [2]: Fourier transformed convolution is equal to product of Fourier transformed convolution components.

$$\Phi\{f_{out}\} = \Phi\{f_{in}\} \cdot \Phi\{g\} \qquad (2)$$

Here Φ is the Fourier transform operator. Obviously, we only have to divide Fourier transform of the output signal to Fourier transform of the spread function and restore the input signal by inverse Fourier transform of the result. In case of noise present we deal with sum of "true" signal and noise.

$$\Phi\{f_{rest}\} = \frac{\Phi\{f_{out}\} + \Phi\{\xi\}}{\Phi\{g\}} = \Phi\{f_{in}\} + \frac{\Phi\{\xi\}}{\Phi\{g\}} \qquad (3)$$

Noise's spectrum $\Phi\{\xi\}$ is much wider than spread function's one as a rule. That's why after division of Fourier transformed output function to Fourier transformed spread function, the result of Fourier inversion is a fast oscillating function, so we receive no information about the input signal. Clearly the simplest way of noise effect diminution is to limit the operative spectral range. The narrower this range the less the noise amplitude in reconstructed signal, but as a result resolution of instrument is worsened too. That's why thin details in input signal would be lost by limitation of spectral range. The constriction of operative spectral range is equivalent to using a priory information about smoothing degree of input function.

This property of the process of reduction to ideal instruments is readily illustrated by our programs. During the simulating experiments one can be assured that noise sets limits on information about the investigated signals.

BRIEF DESCRIPTION OF THE PROGRAMS

Simulation and elimination of instrument distortion for one-dimensional functions can be performed by the "Apparat" sotware [3]. This program is executed on local workstation and requires Microsoft Windows 95/98/2000. The second program was designed for 2-D function processing. It is implemented as web-service and receives its calculation parameters from HTML 4.0 compatible browser on any platfom.

"Apparat" Software

This program was developed by means of Borland C++ 5.5 free command line tools. It uses system modules only, so extra DLLs aren't required. This program was designed to simulate output one-dimensional function when input signal and spread function are given and to restore input one-dimensional function when output signal and spread function are given. The user can simulate noise and can study its influence on the quality of restored signal.

The main program window (Figure1) contains the menu, the toolbar, the graph field and the status line. The program uses both English and Russian labels and messages. The user switches the languages by means of corresponding command from the "Options" menu. The most common commands are placed as buttons on the toolbar. The user can determine the exact value of one of functions if he or she chooses it from the list on the toolbar and clicks on the graph of this function. The function value in this point is placed into the status line. The chosen function can be easily scaled by means of the trackbar on the toolbar.

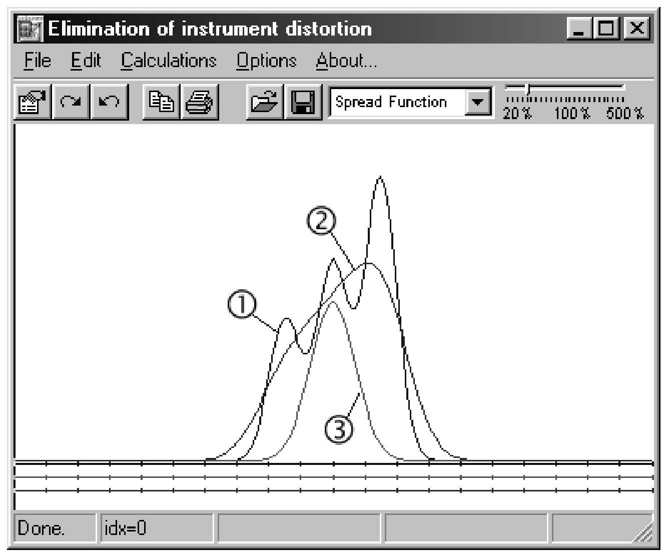

FIGURE. 1
THE MAIN WINDOW OF THE "APPARAT" PROGRAM.
(1 – INPUT SIGNAL, 2 – OUTPUT SIGNAL, 3 – SPREAD FUNCTION)

Various functions charts are drawn with various colors in the graph field. For each chart in the graph field the abscissa axis is drawn with corresponding color. Zero is always located in the center of the graph filed. Each graph presents absolute values of a function. The contents of the graph field can be printed or copied to clipboard.

Calculation starts when the user selects one of the command from the "Calculations" menu. The program places the information about the current step of calculations and its progress into the status line. The user can load input signal, spread function or output signal from file. Fourier-images can't be loaded. They will be calculated. The user can save any function if it is given (or calculated) and visible. The input and output files are texts. The first file line contains the amount of function values, initial value of argument, argument increment and maximal function value. From the second line of the file complex numbers are placed. Real part of a number is separated by space from imaginary part. Except loading from a file, function can be defined as internal one. The “Functions tuning” dialog (Figure 2) allows to configure internal functions, to specify precision and to add noise to a signal. The internal input function is the sum of 3 gaussians. The user should specify for every gaussian the amplitude (A), the abscissa of peak (B) and the C parameter, which determines the width at half-maximum. Spread function can be defined as normalized gaussian (the user specifies the C parameter only and the program recalculates the amplitude to normalize spread function). Fourier transform is performed by means of calculation of integral sum, so there are no restrictions to functions limits.

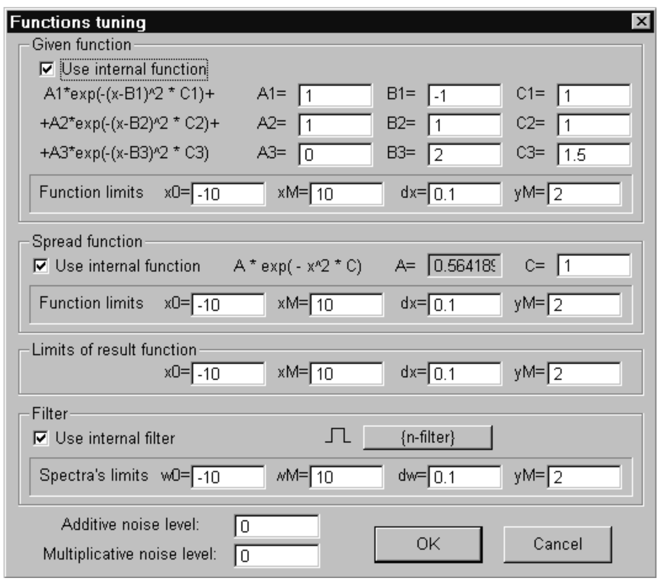

FIGURE. 2
THE FUNCTIONS TUNING DIALOG OF THE “APPARAT” PROGRAM.

The program adds two kinds of noises: additive and multiplicative. The user may specify "noise level" σ in a corresponding field, then the program changes every calculated value f of the output function to $f'=f+\xi f$, when multiplicative noise is chosen, and to $f'=f+\xi Y_{max}$ for the additive one, where ξ is a normally distributed value with zero mean and variance equal to σ^2, Y_{max} – window size, specified in the "yM" field for result function.

For decreasing the noise influence, one can use filtration of Fourier transformed restored function. There are two types of filter selected by the “filter” button:

1) binary filter – in this case the restored function Fourier transform, calculated according to (3), is multiplied by 1 inside of the limits specified in fields “Spectral limits”, it is equal to zero outside of this limits;

2) smooth filter – it this case Fourier transform is also multiplied by 1 inside of “Spectral limits”, but outside them Fourier transform is multiplied by exponential decreasing value with an index specified in the “C” field.

User can load other specific filter from file as well.

Web-based Service

Web-based service named “Instrument Distortion: Simulation and Elimination” (http://dims.karelia.ru/distort) is a web application, which consists of a set of HTML pages, CGI engine and low-level calculation engine. HTML pages provide a user with graphical interface (Figure 3). CGI engine provides interaction between web-server software (Apache) and low-level calculation engine by means of handling user requests, preparing data for calculations and forming result pictures. It is implemented as a set of platform-independent Perl language scripts. Low-level calculation engine performs required Fourier transforms. It is implemented in C language and compiled for particular platform (Linux).

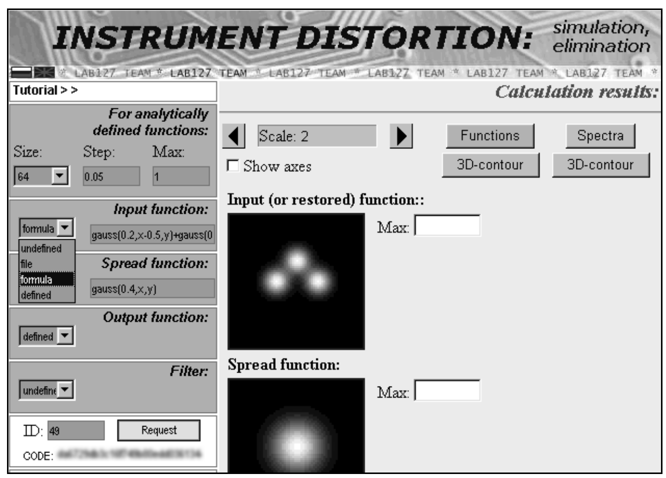

FIGURE. 3
WEB-SERVICE GRAPHICAL USER INTERFACE.

This web-service simulates two-dimensional instrument distortion when the input two-dimensional function and the spread one are defined, or eliminates two-dimensional instrument distortion, when the output two-dimensional function, the spread one and, possibly, the filter are defined. To define a function the user should select the appropriate way of function definition in the drop-down list: "file" or "formula". If user defines a function analytically (by means of formula) he or she should specify the size of the sample, the sample interval and maximal value of the functions. To send data to server when all these fields are filled user presses the "New request" button.

All the requests are registered and numbered. CGI engine stores request information (number, time stamp, client's IP, session code etc.) in MySQL database. Results are stored on the server for 1 hour since the first access. During this time the user can view calculation results: he/she enters its number in the "ID" field and presses "Request" button. User can change some functions of calculated request. Unchanged functions won't be transferred over the network. The low-level calculation engine will use their server copy.

At first CGI engine generates the session code (the "CODE" field). This code expires in one hour. Every time user accesses the server CGI engine prolongs the term of the session code for another hour. After long-time inactivity the other session code is generated. On user's computer the session code is stored in browser cookies. All the registered requests require the session code to be specified. If the specified session code doesn't match the request, the access to data on the server is denied. This feature has a side effect: the user can't access his or her registered requests from the other computer or browser without specifying the correct session code manually. The session code is the "password" for access user's data.

Real function for this service can be specified as formula. The user can compose a formula from arithmetical, logical and bitwise operators of widely used C-like programming languages, from a few internal functions like sine, cosine, gaussian etc. as well:

gauss(σ,x,y) is equivalent to $\exp\left\{-\frac{x^2}{2\sigma^2}-\frac{y^2}{2\sigma^2}\right\}$

smooth(R,σ,x,y) is equivalent to

$$\begin{cases} gauss(\sigma, x-R\frac{x}{\sqrt{x^2+y^2}}, y-R\frac{y}{\sqrt{x^2+y^2}}), & x^2+y^2 \le R \\ 1, \quad x^2+y^2 > R \end{cases}$$

The latter function is useful for specifying as filter.

Table I contains a few examples of analytically defined functions:

TABLE I
EXAMPLES OF ANALYTICALLY DEFINED FUNCTIONS

gauss(0.2,x+0.5,y)+gauss(0.2,x,y-0.5)	smooth(0.5,0.3,x,y)	*cos(2*x*x+3*y*y)*	(1-abs(x)/1.6)(1-abs(y)/1.6)*	
Data files for this service have the same format as the files for the "Apparat" software except for it is strictly recommended to compress data files when transfering over the network. This web-service can handle archives in ZIP (PkZip, WinZip etc) or GZIP (http://www.gzip.org) format. The calculation results are always compressed by GZIP.

The problem of two-dimensional instrument distortion elimination is usually the interest of image processing. So this web-service supports some image file formats: PNG (Portable Network Graphics) and JPEG (Joint Photography Experts Group). When converting image to real values it is supposed that green color gradation "255" corresponds to 1.0. Red and blue color gradations are ignored. The left bottom corner of the image corresponds to the function value for the least argument values.

SIMULATING EXPERIMENTS IN LABORATORY TRAINING

If student simulates an input function as three clearly separate peaks and a spread function as a gaussian with width comparable with peak separation, the result function has no gap, so by visual observation three lines could not be resolved (Figure1). Restoring input function by the "Apparat" program one can receive almost correct input signal. If a noise is added to the output function an attempt to restore the input signal is failed. Even with low values of noises student may receive senseless results (Figure 4). The noise effect can be decreased by reducing the operative spectral range. (Figure 5.)

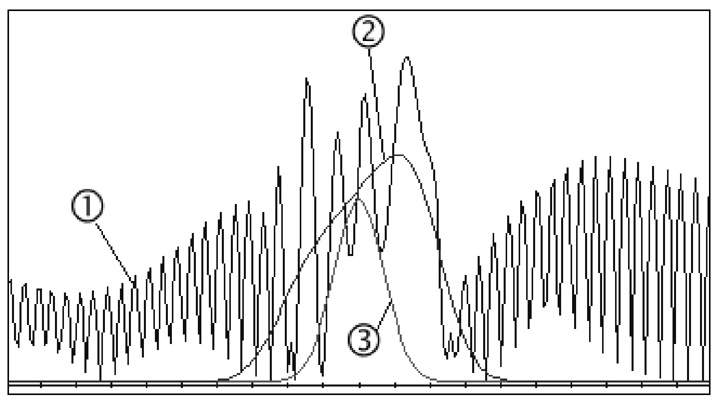

FIGURE. 4
AN ATTEMPT TO ELIMINATE INSTRUMENT DISTORTION.
(1 – RESTORED SIGNAL, 2 – OUTPUT SIGNAL WITH ADDITIVE NOISE σ=0.00001, 3 – SPREAD FUNCTION)

Then student has to investigate the effect of spread function width on the result of reduction to ideal instrument. But if the spread function is wide and the noise level is not low the oscillations disappear with the narrow operative spectral range (Figgure 6), so restored function is now more similar to the output function than to the input one, that is to say the instrument distortion elimination in this case is impossible.

So students have to understand that inevitable noise puts the real limit for optical instruments resolution. The better is the instrument and the narrower is its spread function the lower are the demands to noise level.

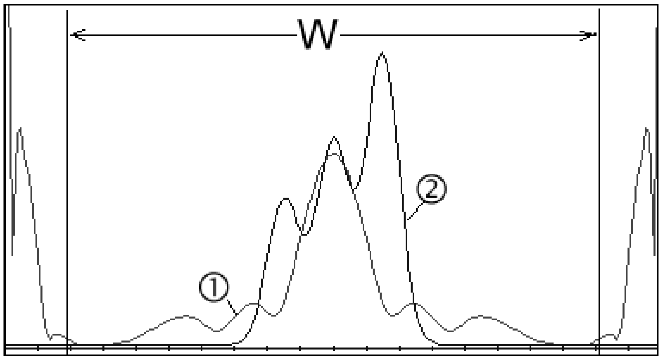

FIGURE. 5
AN ATTEMPT TO ELIMINATE INSTRUMENT DISTORTION
WITH REDUCED SPECTRAL RANGE W.
(1 – RESTORED FUNCTION SPECTRUM, 2 – RESTORED AND "TRUE" INPUT SIGNALS ARE ALMOST IDENTICAL)

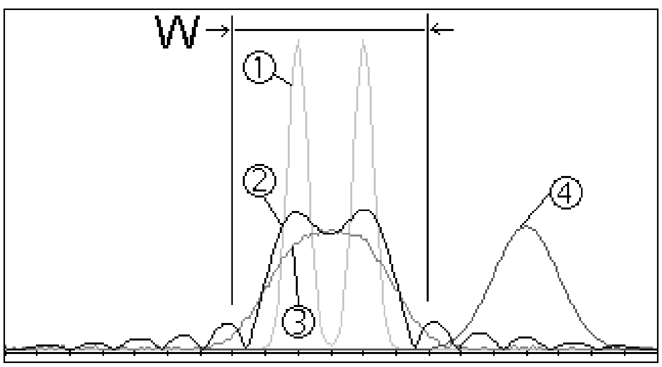

FIGURE. 6
AN ATTEMPT TO ELIMINATE INSTRUMENT DISTORTION
WITH WIDE SPREAD FUNCTION AND REDUCED SPECTRAL RANGE W.
(1 – "TRUE" INPUT SIGNAL, 2 – RESTORED SIGNAL, 3 – OUTPUT SIGNAL WITH ADDITIVE NOISE σ=0.005, 4 – SPREAD FUNCTION IS SHIFTED FROM "NORMAL" PLACE FOR CLEARNESS)

Even if specified noise level is zero, the limited accuracy of computer calculation may have an effect like noises. This effect appears to be the major problem for elimination of 2-D instrument distortion.

If student simulates 2-D instrument distortion by means of the web-service (Figure 7), restoring of input 2-D functions is always a nontrivial problem. Even without special noise simulation, most likely, attempts to restore input signal would failed because of limited accuracy. In most cases reduction of spectral ranges required (by means of filters).

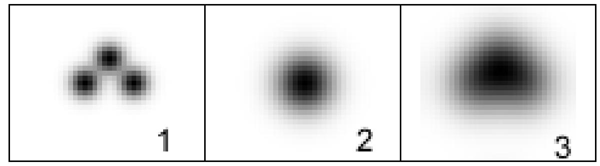

FIGURE. 7
SIMULATION OF 2-D INSTRUMENT DISTORTION.
(1 – INPUT SIGNAL, 2- SPREAD FUNCTION, 3 – OUTPUT SIGNAL)

If student compares various results of instrument distortion elimination when output functions are determined in various ways, he or she will notice that text data files allows to achieve better results than image files (Figure 8 and 9). For text data files elimination of instrument distortion is possible with wider filters. Student should explain this by less accuracy of image data files.

TEACHING FRESHMEN THE NEED FOR SUSTAINABILITY IN THE NEW MILLENNIUM

Dan D. Budny[1] and Larry Ropelewski[2]

Abstract *— When you look at the freshman curriculum, most engineers believe it is necessary for the student to learn proper writing, mathematics, physics and chemistry skills. However, there is also an interest in teaching the concept of Sustainability to students as soon as the freshman year. The problem is how to add material and content to a curriculum that is already full. To address this problem the University of Pittsburgh began teaching Sustainability to the entire freshman class in Spring 2000, by incorporating the concept of Sustainability into the students Introduction to Engineering Course through the concept of writing to learn.*

The educational benefits of adapting a writing approach in the classroom have been widely documented. Writing can serve as a tool to improve the quality of teaching as well as to promote deeper and more meaningful student learning. In this paper we will explore strategies in which writing can be used to both introduce the concept of sustainability and enhance student understanding in introductory engineering courses. To accomplish this goal, students were asked to prepare and present a professional research paper for a "conference". Highlights of the curriculum developed will be discussed. Through a description of the curricula and strategies developed, we hope to provide other science and engineering educators with useful tools to assist them in developing and/or enhancing the use of writing within their own classrooms.

INTRODUCTION

Traditional teaching methodologies have been shown to put students in a role of passive rather than active learning [1]. In addition, traditional instructional methods have also been shown to be very inadequate in terms of the promotion of deep learning and long-term retention of important concepts. Students in traditional classrooms acquire most of their "knowledge" through classroom lectures and textbook reading. A troubling fact is, after instruction, students often emerge from our classes with serious misconceptions [2 - 6].

A significant body of educational research supports the fact that students must be functionally active to learn [7 - 9]. Furthermore, Koballa, Kemp, and Evans [10] note that "ALL students must become scientifically literate if they are to function in tomorrow's society". Scientific literacy is of critical importance for all students at all educational levels.

The *National Science Education Standards* [11] strongly emphasize that inquiry-based techniques should form the core of what it means to learn and do science. Edwards [12] suggests that the publication of the *National Science Education Standards* offer reason to be optimistic that inquiry-based learning will become a central part of science education. Inquiry-based learning strategies originate from the constructivist model and encourage an active, hands-on approach to learning [13 - 14]. The constructivist approach embraces the idea that knowledge cannot be acquired passively [15]. In addition, the National Science Foundation currently has several programs that promote the integration of standards and inquiry-based SMET educational materials and instructional strategies from elementary through graduate school [16].

In recent years, a number of writing techniques have evolved that make use of various writing-to-learn strategies within the domains of engineering, mathematics, and the sciences [17 - 25]. The use of writing in introductory classes may be an effective vehicle for allowing students to enhance their critical thinking and problem-solving skills. Writing can also assist students with the identification and confrontation of personal misconceptions [26, 27].

Science classes are seen by many students to be threatening and intimidating places to be. Tobias [28, 29] also indicates that writing can serve as a means to help students relieve their anxiety and help them unlearn models and techniques that have been shown to be scientifically unsound.

This article describes a novel technique for infusing the concept of sustainability into the freshman engineering curriculum that is based on research the authors are conducting on using writing as a means of providing "hands on learning". [31 - 35]. The techniques to be described here permit students to experience all aspects of preparing a professional paper for publication. The students' experiences culminate with a presentation of their papers at the *Sustainability in the New Millennium Conference* at the University of Pittsburgh. The writing technique was initially modeled at American University then adapted for use at Pittsburgh [36]. The specific courses in which the writing

[1] Dan D. Budny, University of Pittsburgh, Civil Engineering, B74A Benedum Hall, Pittsburgh, PA 15261 budny@pitt.edu
[2] Larry Ropelewski, University of Pittsburgh, Civil Engineering, Pittsburgh, PA 15261.

strategies were adapted, *Introduction to Engineering Problem Solving*, will first be described. The curriculum involved in the development of the writing activity will then be discussed. This discussion will be followed by a summary of the conferences in which students participated. Feedback from student participants will also be shared. In addition, lessons learned during the initial phase of the study will be shared along with how those lessons translated into effective changes for this year. Finally, a summary of this technique will be presented in light of its relevance to science, mathematics, engineering, and technology (SMET) education.

Since the population in the classroom is freshman, their knowledge of sustainability is very limited. In fact the vast majority of the students have never been exposed to the concept. This factor highlights the importance of this assignment and explains why as part of the freshman course syllabus, we must take time away from the typical freshman engineering topics and replace it with a definition of sustainability. Since this program is for all freshman regardless of their major, another concern is the presentation on sustainability must be such that a Civil, Bio or Computer Engineering student will get enough information to develop a definition they can understand. Thus, the first task is to define sustainability.

WHAT IS SUSTAINABILITY

Since the advent of civilization, engineers have sought to alter the environment and shape it in ways that would serve the various needs of society. While our lives today can attest to the success of this endeavor, it has not been without cost. Often times, the alteration of the environment - whether purposeful or unintentional - has led to undesirable consequences. Only in the past several decades have engineers become acutely aware of the consequences of their actions on the environment and society. As a result, growing public demand has led to various legislative and regulatory actions attempting to minimize the adverse consequences of civilization on the environment. Unfortunately, many of these measures - such as the "no net loss" of wetlands policy and the industrial restrictions placed on various parts of the US classified as air pollution "non-attainment" region - often have negatively impacted growth and development. A seeming contradiction between development and environmental protection exists.

In recent years, however, a realization has developed that both development and environmental protection are necessary and that either need not be sacrificed for the other. A growing movement recognizes that environmental protection can and must co-exist with development and must be planned for accordingly. Under the general umbrella of "sustainability", this movement encompasses various facets. "Green Engineering", "sustainable development", "environmentally conscious manufacturing", and "green construction" are some of the terms recently entering the engineering lexicon that describe the move towards sustainability. The confusion surrounding sustainability, is each of these terms means different things to different people. Whether constructing a new highway, designing a new product, or improving a manufacturing process, sustainability issues are at the forefront of challenges today's engineers must face.

What exactly, is meant by "sustainability"? The 1987 Brundtland Report, prepared for the UN's World Commission on Environment and Development, defines it as "satisfying the needs of the present generation without compromising the ability of future generations to meet their own needs"[37]. The 1992 UN Rio Conference on Environment and Development [37] offers a slightly modified version, describing "sustainability" as follows: "the right to development must be fulfilled so as to equitably meet development and environmental needs of present and future generations". Other organizations and individuals propose somewhat different definitions of sustainability. Through all the differing descriptions, however, a common thread remains: sustainability seeks to minimize our footprint in nature, both now and in the future.

Most issues revolving around sustainability, quite naturally, involve subjects traditionally thought of as environmental. These include conventional environmental engineering topics such as waste minimization, pollution prevention and control, and water/wastewater treatment. A second set of issues revolves around energy/resource conservation. It incorporates such items as recycling, alternative fuel sources, alternative fuel vehicles/mass transportation, and energy efficiency. A third group of subjects entails items thought of as environmental ecology. This subset comprises areas such as urban forestry, landscaping and biodiversity.

Although most sustainability issues deal with topics affecting the environment in some manner, one facet of sustainability is unique in that it generally has seemingly little to do with minimizing our footprint on nature, but deals with subjects commonly referred to as "quality of life" issues. Although sometimes not thought of as "sustainability" per se, "quality of life" concerns often are as important, and in some cases, more than the conventionally defined sustainability topics. What exactly is meant by "quality of life"? An admittedly imperfect definition is that they are issues that make human existence more enjoyable, less burdensome, or life extending. Most medical advances, for example, fall under the quality of life definition. These advantages might not impact the environment directly, but often improve human life. Whether it is nano-medicine, nano-probes, new antibiotics, new surgical techniques or new and improved prosthetics, these areas all directly impact the quality of life. Another area of engineering that could be thought of as impacting the "quality of life" is the computer industry. For example, a new piece of software might make it easier to do your taxes, but does not have a direct impact on the environment. There are a large number of other areas that could fall into the "quality of life" definition. Even thought these areas do not directly impact the environment, all of the products must be manufactured, or operate in a computer that must be manufactured and have environmental issues involved with their production or use. Thus, they directly affect the quality of life and indirectly impact the environment.

The final area of "sustainability" that must be considered is that of "trade offs" or balancing environmental, societal and economic factors. Sustainability becomes a study in benefits versus cost. No panacea exists for sustainability. There are no easy, obvious solutions. Each potential answer to a sustainability concern has potential drawbacks. As an example, assume you design a building to reduce energy consumption by using materials and using building practices that reduce the outside air that enters the building. This will reduce the energy use but also reduce the number of air exchanges in the building and could lead to a "sick building syndrome". A second example is the use of alternate energy sources to generate electricity. Wind and hydroelectric power do not produce greenhouse gases as burning fossil fuels do. However, both have other downsides. Areas favorable to wind are also common migratory pathways for certain birds. When a bird meets a metal turbine, the turbine always wins. Similarly, dams required for hydroelectric power often prevent fish from migrating. Economics also plays a part in sustainability. For example, computers and software development benefits the productivity of the average worker. However, the process used in the manufacture of the microchips presents significant environmental challenges. Environmentally friendlier procedures are available but at an added cost. As a final example, assume that an automaker could produce a car that achieves 100 miles/gallon, but costs $100,000. How many of the cars would be sold?

What is more important? No loss of woodland or more homes and industry? Is energy efficiency more important than indoor air quality - or vice versa? Is it more important to produce clean energy or do the birds and fish take priority? What good is an environmentally safe computer or automobile if no one can afford it? The fact is the population will continue to grow, and energy, food supplies, and habitats will need to keep pace to ensure a consistent and acceptable quality of life. The task for all future engineers will be to balance the quality of life against the environment against the cost to develop the best solution for us and generations that will follow us.

BACKGROUND

All students are required to take four core engineering courses during their first year. There are two zero-credit seminar courses [38, 39] and two three-credit introductory problem solving courses [40] that are a part of this core. ENGR0011 and ENGR0012 are required first and second semester three credit courses, for all freshmen engineers that meets twice a week for 2 hours in a computer-equipped classroom. They are *integrated* courses that have the overall goals of:

1. Teaching the basic computer skills (Excel, Matlab, C), and their role in problem solving,
2. Introducing teamwork,
3. Improving writing and communication skills,
   a. Introduction to Technical Report Writing,
   b. Effective Use of the Library;
4. Promoting and encouraging good programming practices; and
5. Illustrating the role computer programming plays in solving real-world engineering problems, and
6. To begin understanding how material in the basic sciences and mathematics is used by engineers to solve practical problems of interest to society.

It is the experience of the faculty that students know very little about the actual operation of a computer or computer software as problem solving tools. The students are good at using AOL instant messenger, and finding music files on the web, but when it comes to organizing files in directories, or organizing their thoughts into a structured program the vast majority of the students are lost. Thus, the main focus of ENGR0011 is to begin the process of structured thinking then ENGR0012 expands this concept into the structured programming area.

The class sections are taught by faculty members from various departments within the School of Engineering, and the course topics focuses on material that overlaps with various disciplines in engineering. Emphasis is placed on the application of various computer-based tools to solve real-world engineering problems. The course also illustrates how engineering differs from, as well as how it coalesces with, the disciplines of science and mathematics.

In addition to the various activities related to problem solving, students are also exposed to a richer and more robust writing experience in both ENGR0011 and 0012. This experience involves the preparation of a written research paper and oral presentation. These activities will now be described.

DESIGNING THE INTEGRATED LIBRARY RESEARCH PROJECT

To introduce sustainability through the concept of a writing assignment, a communication link had to be installed into the course. This link was in the form of introducing the various word processing software and computer presentation software. Thus, from the students' perspective the writing assignment was a requirement for the communication portion of both courses.

The Spring writing assignment is introduced early in the Fall semester, students were informed that one of the key components of the spring course would be the preparation of a formal written paper for publication and presentation at a conference to be held at the end of the second semester. Through the context of a conference, students are now introduced to the culture of academic research and the scholarly communication system and how the engineering profession interacts with this skill. Specifically the educational objectives of the library including introduction to some of the library's resources and research processes, and introduction to critical thinking skills to analyze the validity and utility of information are incorporated into the project.

Given that Pitt uses an integrated curriculum approach for their freshman courses, students were told that where possible, their papers should relate to topics covered in the fall or spring semester of their Physics, Chemistry, Calculus or Engineering classes. In addition, students were to link their chosen topics to an area of engineering using the idea of sustainability in the new millennium as the common conference thread. The key idea was to expand upon the concept of curriculum integration by having students merge material from their core courses with material they had learned in their introduction to engineering seminar courses and explain how the product they were researching dealt with the various science topics they were learning and how the engineering profession dealt with the concept of sustainability when designing this product.

To prepare the students for this Spring semester project, it was decided to introduce the students to writing in the Fall semester. It was decided that a trial run of writing and presenting a technical paper to a small group of their peers using PowerPoint software would best prepare the students for the conference in the spring semester. The ENGR0011 faculty agreed that the overall theme of the Fall library research project should focus on the student's exploration of an area of engineering that interested them. Thus, in addition, to the concept of sustainability, the freshman program faculty and advisors wanted the students to be able to answer the question "What is an Engineer"? and how does sustainability fit into every field of engineering?

Each component of the research project included a statement of purpose (or learning objective) so the students would understand why they were doing this work. Research/Resource Guides for each assignment were designed by the library staff in order to supply the students with additional guidance to the resources they would need to consult.

Within the library, the librarians and staff met to discuss the project. A binder containing the Library Research Project was kept at the front desk of the Engineering Library. All of the library staff became familiar with the project; they were aware of which assignment the students would be working on in any given week, as well as the resources students were being asked to access and use.

Throughout the second semester, students were exposed to all aspects involved in the preparation of a formal paper for publication. These aspects included: responding to a call for papers, being notified of the acceptance of their abstracts, conducting the necessary research, preparing and submitting a paper for review, conducting a review, and receiving and utilizing the feedback to prepare a final paper. Each of these items are further described and illustrated in the sub-sections presented below.

The Call for Papers

The conference call for papers was distributed at the beginning of the semester, see Figure 1. Students received a paper copy as well as an electronic copy of the call via the class web page.

Figure 1 Call for Papers

Abstracts are now being accepted for the ***Third Annual Sustainability in the new Millennium Conference*** to be held on **April 5, 2003** at the University of Pittsburgh in Pittsburgh, PA. A wide range of topics will be considered. Where possible, papers should involve some topics listed in the fall or spring semester Physics, Chemistry, Calculus, or Engineering course syllabus.

Possible presentations/paper topics include (but are not limited to):
1) Historical, current, or futuristic views on a physics topic related mechanics, linear, or rotational motion, collisions, energy oscillations, waves, electricity, magnetism, light, color, quantum mechanics, or other topics;
2) Historical, current, or futuristic views on a chemistry topic related to kinetics, entropy, liquids, gases, thermodynamics, materials science, chemical relations, ionic bonding, organic chemistry, polymer chemistry, biochemistry, nuclear chemistry, or environmental topics;
3) Historical, current, or futuristic views on computer science topics related to software development, the internet, programming languages, or other related topics;
4) Physics, computer science and/or chemistry as it relates to the design, development and/or function of a commonly used devise (e.g. What is the physics involved in a burglar alarm? What is the chemistry involved in batteries or fuel cells? How is sound created for a movie film? How does the detector in the light meter of a camera work?);
5) Science or computer applications and public policy issues;
6) Science or computer applications and social issues;

Note: Each paper must not only address the above topics, but also discuss some aspect of sustainability.

The purpose of having students prepare an abstract was threefold. First, the preparation of an abstract gave students a sense for how the abstract submission process is handled for a professional conference. Second, it provided students the incentive to choose a topic for their papers early and to begin to focus on the research aspects of the project. Third, it was obvious that many students had never been asked to prepare an abstract before. Many students were challenged to effectively summarize a paper they have not yet written into a 150 word abstract. Thus, this task required the students to think within the "big picture".

To manage the process, the 380 students were paired with another student with common interests. This reduced the number of abstracts to 190.

All abstracts were submitted to a web-based electronic format. The electronic submission of abstracts encouraged professionalism from the outset of the paper preparation process and facilitated a more efficient and effective review.

Preparing the Sessions

Once the submission process was completed, all the student abstracts were reviewed by the course instructors and organized into common theme sessions. The abstract review allowed the instructors to prepare a preliminary conference schedule and to make sure the paper topics were consistent with the call for papers. Some students were asked to revise their abstracts because their initial topics did not parallel the conference theme closely enough.

The final conference will have approximately 30 sessions with approximately 6 papers presented per session. Because of the large number of papers to be presented it is not possible for one person to perform all the associated review tasks. To address this issue, 30 alumni volunteers from the Pittsburgh area together with 30 faculty volunteers were solicited to act as co-chairs for each session. Each session was co-chaired by one alumni and one faculty volunteer. These individuals also served as reviewers for the papers to be presented in their sessions. Over the past 3 years, the conference has had the following sessions topics:

> Chemistry Issues, Computer Issues, Bio-Engineering Issues, Mechanical Issues, Environmental Issues, Energy Sources, Transportation Issues, Military Issues, Physics/Civil Issues, Communication Issues, Medical Issues, Structural Issues, Electrical Issues, Industry Concerns, Future Issues, Manufacturing Issues, New Millennium Issues, and Aviation Issues.

A review of the session titles shows that the conference theme of sustainability has reached well beyond the classic “green construction” or “green engineering” definition used by many people. Thus, the goal of raising the awareness of sustainability has been achieved.

Preparing and Submitting a Formal Paper for Review

When students initially received notification that their abstracts had been accepted, they were given a copy of the formatting guidelines to be followed as they prepared their papers. The guidelines that were given to the students were essentially the same guidelines given to authors submitting a paper to the ASEE Frontiers in Education Conference. The paper submission process was a web-based format.

Receiving Reviewers’ Feedback

All students’ papers were subjected to a formal review process. To facilitate this process, each of the 180 teams of student authors met weekly with to give a short progress report. During the first year of the program, this meeting was with a team of TAs whose assignment was to supervise the students. In the second and third year of this conference, this task has been transferred to the undergraduate mentors. Thus, the success of the involvement of the mentors during the first semester, has resulted in expanding their involvement into the spring semester.

During these meetings students must demonstrate completion of various milestones set by the faculty. For example, during one weekly meeting students were required to submit an extended 2-page outline of their papers, during another they were required to submit a copy of the articles they were using for their papers, and during another they were required to submit short summaries of each of the articles they had collected thus far. Table 1 lists a summary of the various activities for each week.

The paper review was a multi-step process. After the abstracts were submitted, the ENGR0012 faculty initially reviewed the abstracts to establish the 30 sessions. Students were then required to submit an extended outline of their papers. This outline was posted on the conference web site so the session co-chairs could review the abstract and outline. The session chairs then met with their students to discuss the paper outlines. After this meeting students prepared the draft version of their papers and submitted it electronically, the week before spring break. The co-chairs were responsible for reviewing these submissions for technical content. A second meeting with the students to discuss the reviewers' comments was then held. In addition to being reviewed by the co-chairs, each paper was also reviewed by a faculty member in the English department. The reviews conducted by the English faculty members focused on writing style, form, and grammar.

An additional peer review process was also part of the process. The usefulness of this approach has been widely documented [41, 42]. Thus, in both courses, every student was assigned another student's paper to review. Since the students were paired in teams to write the papers, and each student did their own review, each paper actually received two student revfiews.

In summary, this process produced 5 independent reviews, one from the English department, one from an alumni, one from a faculty member and two from students.

Table 1 List of weekly activities in review process

Week of	Assignment	Comments
08-Jan	No Meeting	
16-Jan	- Choose partner for project	
22-Jan	- Turn in preliminary topic	**Purpose** --- To get the students to begin to research their topics and read the articles
29-Jan	- Bring in 3 articles on topic - Explain 1 randomly picked article - Explain their topic a little and what they want to explain in their paper	**Purpose** --- (1) To have students continue to research their topics and read the articles (2) To get students to relate sustainability issues to their chosen topics
05-Feb	- Bring in 3 articles on topic (2 from mag/journal) - Explain 1 randomly picked article - Identify 3 sustainability issues and explain how they relate to the student's chosen topic	**Purpose** --- (1) To get students thinking @ how they will write their paper. (2) To get students actually writing parts of their papers
12-Feb	No Meeting Students are meeting with their session chairmen	
19-Feb	- Bring in copy of outline - Talk to the outline and discuss what they want to discuss in their papers - Bring in 1 page typed paper about some topic in their outline	**Purpose** --- (1) To continue to have students actually writing parts of their papers. (2) To get students writing their bibliography and procure additional sources if required
26-Feb	- Continue to talk to their outline - Bring in copy of bibliography - Bring in 1 page typed paper about some other topic in their outline	**Purpose** --- Explain peer review process
05-Mar	Spring Break	
12-Mar	No Meeting Students are meeting with their session chairmen	
19-Mar	- Bring in peer review papers - Explain peer review process (meeting chairman)	**Purpose** --- To get the students thinking about their presentation and to start putting it together
26-Mar	- Bring in preliminary outline for presentation and discuss what points the student wants to make	**Purpose** --- (1) To get the students to prepare their presentation for the conference. (2) To go over the presentation and make corrections/ suggestions
03-Apr	- Bring in charts the student wants to present to the conference or a hard copy of their power point presentation - Talk to the charts/hard copy.	

THE CONFERENCE

Students utilized the reviewers' comments to prepare final copies of their papers. Typical papers ranged in length from 5 – 8 formatted pages. Because of the magnitude of the conference, the conference proceedings was only available on line, however, a matrix was created and distributed at the conference.

The students prepared and made use of overhead transparencies, PowerPoint slides, and demonstrations during their presentations. Students were also asked to wear appropriate attire for the conference.

Students were given 15 minutes for their presentations and then allowed two minutes for questions. It was not possible to hold the conference during regular class time because of the sheer size of the conference. Thus, the conference was held from 8 am to 4 pm on Saturday, with lunch being provided.

The following section highlights student impressions regarding their overall experiences during the paper preparation process. In addition, feedback received during Phase I from students via a written questionnaire is summarized.

RESULTS

In the first year we were able to design the basic concept of the writing and library integration into the freshman curriculum. As faculty and staff we learned a lot about what could and could not be expected from the students, how to introduce the material, how to grade the student presentations, what type of handouts and grading keys were required, what could be expected from the mentors, and all the various logistic concerns. Thus, the main results we obtained during the first year were administrative issues. We also discovered that the content in the two - zero credit seminar courses had to be totally redesigned. Thus, in the second year we moved the department presentations from the Spring semester to the Fall, we added open house presentations into the Spring semester, and we extended the peer mentoring to the second semester ENGR0082 course. In addition, we added an intensive one week mentor training program to the week before school started. In this training we exposed the mentors to training in the areas of advising, diversity, communication skills, and mentoring skills.

The results from the Fall semester of the second year supported the changes we made as the students' acceptance of the project was much more positive than the first year. Based on the feedback from the students during their spring semester registration period at the end of the Fall semester, the project meet the advising concern, since the vast majority of the students stated the project made self evaluate their choice of major. The students either found that by researching their fields and talking to fellow students in their mentoring class they were questioning their choice and wanted to learn more about all the fields of engineering, or were now convinced the field they selected was the correct field for them. This is a very important result. One of the largest problems faced by advising centers is students changing their major after they have been taking classes for 2 - 3 semesters. Thus, by having the students research the concept of sustainability, we are finding that the students are also doing the same career exploration in the first semester of the freshman year, that typically takes place during their third of fourth semester. This has the potential of saving the student a large amount of time and money.

It was also clear that for the project to be successful, you must have the assignment well organized with handouts that can walk the students through the process. You cannot assume that a freshman knows how to write a report, this was the biggest error we made in the pilot.

By the end of the semester a number of goals were reached with the first writing assignment. First the students were exposed to the library and how to conduct a research paper. Second the students were exposed to the actual skills required to write a formal paper and give an oral presentation on an engineering topic. The last and most important concept was the students researched an area of engineering that they thought was interesting, and during this process they discovered a product or topic that dealt with sustainability in that profession. Thus, by writing the fall semester paper they discovered a topic for their second semester paper.

During the Fall of the second year we also starting getting feedback from the faculty teaching the Second year courses in the various departments. As one faculty member stated he was "blown away by the quality of the writing of his students compared to previous years". This also confirms the finding of the English department when they stated that the quality of the final papers was equivalent to the results that could be expected from taking a 3 credit writing course. Thus, the goal of improved writing skills was also meet by the project. It is clear that the main reason the writing skills of our undergraduates is so poor is because they do not know how to use the library to write a research paper, and the results we are getting this year support the concept that if you teach them how to do it they will improve their skills.

FEEDBACK FROM STUDENTS

Near the beginning of each semester, the students were quite apprehensive about the prospect of preparing a formal written paper. None had ever been given a writing assignment of this magnitude before. Although the students had done some writing when they were enrolled in the foundation course, ENGR0011, the task facing them seemed quite daunting. In addition, many students expressed anxiety regarding the fact that they were also being asked to present their papers orally. Comments from students suggested that they felt they would never be able to fill the 10-minute time period allotted them for their presentations. In reality, once students had completed their written papers and had prepared their materials for presentation, most found that they had too much material to fill the 10-minute time slot! Thus, the real challenge faced by most students was the condensation of their papers into a 10-minute presentation. Each and every student author was, however, successfully able to present their papers within the given time period.

On a questionnaire given students last year, students were asked to describe their overall impressions regarding the conference paper assignment. Typical student responses included:

- *I've never written a technical paper like that before. The topic was much more involved - and required you to really understand what you were writing about.*
- *I thought this was a difficult assignment that taught me a lot and was worth doing. It was a lot of work, but after doing it, I felt like I learned a lot. I never had to write a technical paper before and I'm happy that I can now say that I wrote a conference paper.*
- *I learned a lot about a subject that I would not otherwise have learned about. I had never written one of this magnitude, or that required so much in-depth research. We were allowed to pick the topic - which was nice.*
- *I have never written any form of technical paper at all. At first, I was not very excited about the idea of writing such a paper, but I did feel that I had a very valuable experience. I feel that I have learned so much - beyond physics principles. I also appreciated you forcing us to do rough drafts, so I was able to pace myself and put more effort into it than I otherwise would have.*

The following questions to sustainability were also part of the survey:

- How did the conference activities (research, paper, presentation) help teach the concept of sustainability as it relates to Engineering?
- Was the concept of sustainability adequately explained in the Freshman Seminar?
- Did the TAs do an effective job explaining the concept of sustainability in the weekly meetings overall and how it related to your topics?

On a scale of 1 - 5, with 5 high, the students responded an average of 3.5 on each of these topics. Thus, they found the paper did indeed help introduce them to the concept of sustainability. We also pre and post tested them on their views of what requirements engineers have should have related to issues involving social responsibilities and ethical concerns. On each item the difference between the pre and post scores was on the average of 20%. Thus, the students are developing an understanding on the need to consider the environment and society when they make their engineering decisions.

On the short answer survey questions the general response was they did not know anything about sustainability before the activity or they thought it was just an environmental engineering concern. Thus, with this rather simple task we were able to introduce all engineering students to the concept of sustainability and got them thinking about how sustainability could be included in all engineering projects.

The most interesting result, however, is not during the freshman year, but after they have completed a Co-op or intern work assignment during their second or third years. We continue to survey the students after each of their years at the university, and each year we ask them to evaluate their freshman experience. What we are finding is when you ask a second or third year student the same survey questions, the scores on the questions continue to increase with each year. We are finding that freshman do not truly understand the value of the conference experience, however, once they experience an opportunity to spend time in the work force they are being asked to consider many of the same topics we discussed in the freshman sustainability conference. Thus, the conference is introducing them to a topic that was never discussed in the past, and is preparing them for issues in the work force that deal with society, and sustainability.

SUMMARY AND CONCLUSIONS

All aspects of the conferences, from submission of an abstract to the formal submission of a camera-ready copy of their paper for publication and presentation, allowed students the opportunity to link the active process of writing to sound, scientific content. In addition, these activities allowed students to demonstrate their understanding of a topic or set of topics using their individual learning styles. This activity also provided the instructors with an additional assessment tool outside of the limits of more traditional assessment measures.

At the conclusion of the conference, it was clear that the students felt that all of the time, energy, and hard work they had devoted to the preparation for the conference had paid off. Many expressed that they had experienced a fairly steep learning curve on both the content covered as well as the rules and regulations they were required to follow as they prepared their formal papers. In addition, many students expressed gratitude for the opportunity they were provided to participate in such a formal and professional activity.

The underlying premise is that <u>all students</u>, no matter what their gender, cultural, or demographic backgrounds, can learn! In a recent report on its review of undergraduate education, the Advisory Committee to the National Science Foundation's Directorate for Education and Human Resources concluded that "… while K – 12 programming can expand the pool of those interested in pursing careers in SME&T [Science, Mathematics, Engineering, & Technology], it is at the undergraduate level where attrition and burnout can be most effectively prevented. What we in SME&T education must do is to concern ourselves with *all* students, not just those who historically have been represented in science, mathematics, engineering, and technology. Such a breadth of concern has important educational benefits as well, as it will force us to think more about how individuals learn and recognize what research has made clear: that there are differences in learning style which profoundly effect achievement. And let us not forget that increasing student achievement in SME&T education is exactly what is needed [43]" (p. 28).

Writing has proven to be an effective way to assist students in articulating their thoughts. In addition, the opportunity to research and then write about a topic of personal interest can allow students a chance to demonstrate their understanding in a way traditional assessment measures do not permit. Hence, the application of a writing component into a course has enormous potential within both science and engineering communities.

DIRECTIONS AND CHALLENGES IN INFORMATICS EDUCATION ON ENGINEERING AND COMPUTER SCIENCES COURSES

Clara Amelia de Oliveira[1]

Abstract *— XX Century culture has emphasized specialization paradigm in all knowledge domains. Globalization times have increased complexity on this scenery putting real challenge to earth people, including Engineering and Computer Sciences domain. In this direction, this paper presents an Educational methodology-the Thematic Oriented Methodology. The concrete experience occurred on a Computer Programming Introductory discipline, on Engineering and Computer Sciences courses. This pedagogic experience pointed out how important is to built a clear object of study definition under Complex Though approach as a knowledge domain. The Complex Though is, by its side, close related with XXI Century educational demands, as proposed Edgar Morin, from UNESCO Itinerant Educational cathedra. The central question to be discussed here is, how new curricular trends can profit from this approach? Some conclusions enhance thematic oriented proposal as an answer to educational demands under globalization approach.*

Index Terms — Complex Though, Computer Sciences and Engineering Education, Educational Methodology Thematic Oriented Methodology.

INTRODUCTION

The presence of Informatics on modern civilization has been a central discussion point on several scientific forums, all over the world. But the informatics contribution on education can be wider than just referring to instrumental support, specifically on technological careers educational scope. Engineering and Informatics curricula have a deep question to be faced, at first. It is how to organize contents, such way, students can develop, both, analytic thinking, required in focused knowledge aspects, and synthetic thinking, required on multifocus knowledge aspects. Some tasks refer to modeling systems practice under very complex environments, but, at same time, at closed systems, leading with specific details. The question is how to promote, pedagogically, this movement causing internal link between broad and specific knowledge aspects? Can engineering and informatics students, at same time, pay attention on special inner machine tool contents, aligned with high abstract values, as society engaged citizens? This is possible, for several reasons, and the simplest one is that because this is natural. This is not only possible, but it is desired on all kind of knowledge domain, including Engineering and Informatics one. Those educational trends looking for necessity of synthesis at curricular level, have been proposed by ABET criteria 2000 [1], as a directive, for engineering careers, emphasizing synthetic approach. Those principles are, also, in accordance with generic educational trends present in recent documents from UNESCO, looking for Complex Though studies proposed by Edgar Morin Itinerant Cathedra [2]. There is notable convergence of educational principles related with engineering, and Informatics, careers because of nowadays demands of modern professional profile. In this direction, there is available a theoretical tool, proposed by Nygaard, applied, at first, in information systems modeling [3], but, ready to support education systems demands, as it will be discussed below.

THEMATIC ORIENTED EDUCATIONAL METHODOLOGY AS A PEDAGOGIC AXIS ON INFORMATICS AND ENGINEERING CURRICULA

Thematic Educational methodology is a proposal that is developed around thematic as a pedagogic axis. The central idea of Thematic Oriented proposal is to lead with enough wide categories of knowledge. Because of wide scope it implies in a long life cycle time activities around proposed activities named as projects. On this sense, a project is a thematic implementation traducing a kind of open knowledge domain category, in witch technical to social, ecological, or economics aspects, can be inserted. It is crucial here the definition of level of generality of object of study. Object of study level must to be carefully defined at curricula instance because of its pedagogic potentiality. It creates new relationships between disciplines, altering traditional disciplines structure. Figure 1 illustrates a pedagogic choice between two different levels of generality associated to the same thematic, or, object of study. It refers to *Water studies* thematic. Water thematic can be chosen at high level of generality, for example, as an Earth Life thematic under an open knowledge domain. It can be chosen at low level of generality, for example, as a Physical Chemical thematic, under a closed scientific knowledge domain. This choice is what is relevant at curricular proposals.

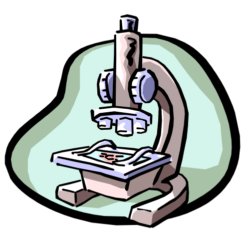
This educational proposal is theoretic inspired in several authors ideas. It expresses a concrete pedagogic implementation of Bertrand Meyer Inverted Curricula idea.[4]. At curricular level, Thematic Oriented design

[1] Clara Amelia de Oliveira, Dept. of Informatics, Technological Center, Federal Univeristy of Santa Catarinna- INE-CTC-UFSC, CxP.476- 880400-900, Florianopolis, Santa Catarina, Brazil, clara@inf.ufsc.br

affects directly basic sciences disciplines organization. Inverted Curricula trend, in terms of disciplines contents suggests insertion of more specific disciplines later on the course schedule. For example, Numerical Methods, Physics and Maths specific contents are better explored, later, on curricula disciplines, when projects are associated to more sophisticated, or specialized categories of knowledge. By the other side, those contents can, indirect, be present, at some first basic approach also in projects at fresh curricula disciplines. Same way, other very abstract and wide aspects as insertion of technologies in society are suggested to be discussed early at all kinds of technological curricula. In addition, it does not matter if curricula is divided in pieces of knowledge called disciplines, or even, projects. At this discussion level, both terms can be treated as synonymous without lacking the pedagogic proposed idea.

Object of Study: WATER
Level of Generality choice:
level 1 (+ generic)
level 2 (– generic)

Level 1 - *Water* associated with *Earth Life* thematic (+ generic)



Level 2 - *Water* associated with *Physical-Chemical* thematic (- generic)

FIGURE. 1
DEFINITION OF THEMATIC LEVEL OF GENERALITY.

But, Thematic Oriented methodology [5] is not, only, a pedagogic proposal to treat knowledge. Actually, it affects the other educational aspects belonging to a teaching/learning environment, such as instrumental issues, evaluation process. This is called Complex Educational Approach that is the central axis of this pedagogic proposal.

A MODELING TOOL TO TREAT AN OPEN KNOWLEDGE DOMAIN

First step: definition of Object of Study, or Thematic searching to a high level of generality. After defining the object of study, as a generic thematic, it emerges the complex view, or open knowledge domain perspective. This aggregates flexibility aspect regarding the way knowledge is treated. This direct affects the way pedagogic tasks can be developed. After this first step, treating knowledge as a wide scope, it emerges a second and important step.
Second step: what a kind of tool is adequate to support open knowledge modeling? This step is related with the necessity of an adequate tool just to support implementation aspects on, day by day, pedagogic activities. What a kind of modeling tool could help and could be closely harmonic to lead with such broad knowledge categories under complex approach? Let's see.

Tribute to Nygaard and Dahl – Two Eminent Scientists of Complex Modeling in Informatics

The answer to pedagogic demands on complex, or open, models of knowledge is given by an Informatics modeling tool. Complex modeling in Informatics is related with Object Oriented tool principles. Those principles were derived at XX century, by the years sixties. The abstract operation principles are operational possibilities, just contributing to convert open models from seeds to big trees. XXI century, certainly, will profit of this. Unfortunately the author of this theory, Professor Kristen Nygaard, emeritus professor of Department of Informatics of Oslo University is died some months ago. The author of this paper met Prof. Nygaard several times and think he was a great man, human people and great citizen. But, what is important is that his voice go ahead because, today, many scientists can develop open models over those derived Object Oriented formal principles. They are special applied and known at computer systems domain, or even, at least, in internet packages. It is possible that, nowadays, young scientists do not remember that some time ago, computer programming and thinking followed a sequential approach. Its evolution toward structured approach was a wonderful but this emphasized horizontal modeling. This Object Oriented formal organization was particular useful in increasing complexity models. Object Oriented practical implementation occurred through Nygaard and Johan Dahl hands. The partner of Prof. Nygaard, Ole Dahl, was also professor from Oslo University. He has implemented Simula compiler on the sixties. Both passed away some month ago, causing consternation on scientist community.

Harmonic wedding between Object Oriented Modeling Tool and Complex Knowledge Domain

Complex approach finds a natural link with Object Oriented modeling tool if pedagogic axis is defined as a broad Thematic as the scenery adequate to build a curricular design. Here it can be taught about engineering curricula, informatics or elsewhere, it does not matter.

It is considered that the abstract operations are the core of Object Oriented tool. They allow vertical models development. It is in accordance with nowadays necessity regarding complex knowledge models. Informatics domain as information models solver, deep benefit itself from those principles. By the other side, vertical development of knowledge representation can be limited according with modelers objectives. At Informatics domain, the roof of generality can be a concrete project or machine associated with its costs, or its time to run. This is equivalent to a less generic level in terms of knowledge modeling. This is something like level 2 presented on Figure 1. Generality of thematic modeling is a crucial aspect because potentiality of Object Oriented thinking will be limited by this issue. What is absolutely positive is that Object Oriented tool is always potent because of its intrinsic generality of principles. It does not lack the horizontal domain enhanced on structured modeling, which was the precedent modeling paradigm, great performed on the years seventy. Object Oriented proposes includes vertical, as well as horizontal modeling. So it is important to reinforce necessity of changing way to treat knowledge to arrive to globalization times demands. In the case of Object Oriented potentiality, it grows up, exponential way, in complex models associated with real world open domains. In this case, knowledge categories are treated all together. They include economics, ethics, bio, eco and technical issues. Engineering domain, in this sense, seems to be more harmonic than Informatics because it usually, is more generic than Informatics domain of knowledge. So it profits the maximum from this knowledge modeling tool. Object Oriented approach will transform, in the future, the vision also in Informatics, putting it, in a harmonic place of knowledge category, not, at all, at the top of knowledge category, but as a support of knowledge humanitarian vision.

THEMATIC ORIENTED METHODOLOGY TO FACE GLOBALIZATION DEMANDS AT CURRICULA PROFILE

New trends at curricula level points out integrative directives to face globalization context and its demands. In this sense, thematic oriented methodology represent the union of those aspects because it affects the deeper level of contents organization as a central directive. And what is this deeper level? It is the new look to knowledge categories as open knowledge ones. An open knowledge vision facilitates to increase towards vertical direction all pieces of knowledge. Here it is important to perceive that the way you treat knowledge affects much more educational structure than pedagogic practices. Despite of this, all practices, including instrumental one are benefited by integrative curricula trend. This occurs because the integrative view offer a broad approach for all kind of minds, not only to experimental oriented minds but also to abstract ones.

Thematic as a Complex Object of Study

Complexity is a key word considering new professional profiles at globalization context. Complex, following Edgar Morin cathedra about Complex Though, is *what is treated together with its wide context*. This also can be traduced by what can not be fragmented[6]. Here appears the definition to generality level to be associated with thematic as a complex object of study. So, this way, thematic is treated as a real world object of study. There is to say, thematic will be modeled during a long period of activities. Their possibilities are from a discipline period till a whole curriculum built around disciplines or even projects units. In this sense thematic is equivalent to a meta project that can be developed creative way under infinite possibilities.

Pedagogic Directives under Thematic View

There are two pedagogic directives to be considered by thematic vision in education. The first directive is the bi-directional movement between knowledge categories, from generic, as ethics, ecological, economics and social ones, to specific categories, as maths physics, computer sciences ones. The second pedagogic directive is the inversion of general direction of knowledge categories to be treated. The suggestion is to treat first generic categories, and, the specific categories will appear, according to necessity of self inclusion, permitting understanding of thematic aspects increasing. Those two directive alter curricula vision because knowledge is distributed around projects of with longer life cycle than traditional specific knowledge vision.

Some Concepts related with Thematic Approach

Depending on the level of generality, thematic exploration demands a long time cycle to develop all categories to be treated in thematic context. Considering traditional curricula organization built around disciplines, Thematic Life Cycle corresponds, at least, to a whole discipline. It is a previous condition to consider thematic as a complex object of study. Here it appears, again, the concept of complexity related with open knowledge domain. This concept is different from specific concept of complexity of parts, concerning to closed domains of knowledge. For example, complexity of algorithms, or, math complexity are related with closed domain of knowledge. Both, algorithms and math complexity, appear, naturally, embed as part categories, or horizontal categories of open knowledge domain. They correspond to horizontal development of knowledge, encountered in close, or specialized knowledge domains. So it is important to perceive that open knowledge domain is not at all opposite to closed knowledge domain but the open domain embed the close one.

CONCRETE EXPERIENCE WITH THEMATIC APPROACH AT FRESH MAN CURRICULA

After thematic definition level (Figure 1), several versions of meta project implementation are presented (from Figure 2 to Figure 4). Thematic approach here refers to a fresh man curricula experience. Water Studies is related with at government level. The treatment of knowledge, traduced by several project versions, is supported by 'abstraction principle'. Through abstraction, a generic thematic can be treated as several concrete projects with increasing complexity. This way, what is already defined as thematic can be traduced as a meta project. Each project to be implemented during semester, or annual pedagogic activities, normally called disciplines, is a stage of the same metha project. Figure 2 shows a project proposal at energy ministry level. It appears generic aspects as ethics, economics and social ones. Of course here there are no technical details, not at this first moment. They will appear, step by step, soon, as illustrate by figure 3 and figure 4.

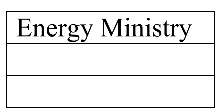


FIGURE. 2
PROJECT INITIAL VERSION: HIGH LEVEL OF GENERALITY AND HIGH LEVEL OF ABSTRACTION.

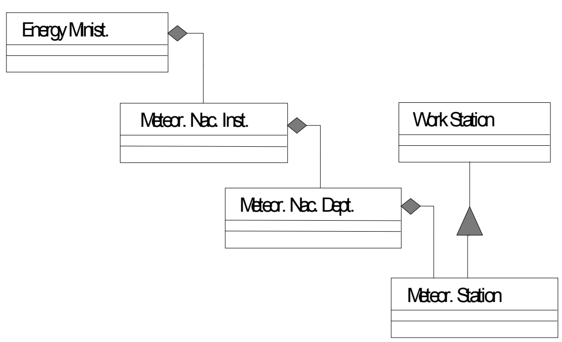

FIGURE. 3
PROJECT VERSION ONE – GENERIC KNOWLEDGE LEVEL.

Figure 3 shows project version N. It is later developed over project initial version. Thematic is still the same. Here they are included aspects, as governmental structure to treat this theme, and, also, it appears some specific aspects, related with professional career technical contents.

As time goes by, thematic exploration arrives to more specific stages as you see at Figure 4. This example refers to details of rain follow data which is manipulated under a math structure of data of an information system. Math, physics and informatics specialized knowledge grow up, as the versions are implemented.

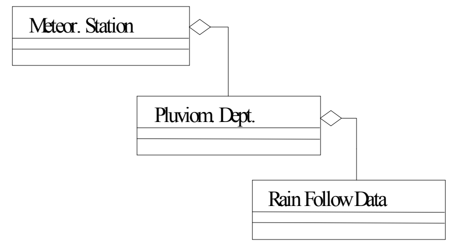

FIGURE. 4
PROJECT VERSION N – SPECIFIC KNOWLEDGE LEVEL.

CONCLUSIONS

*On the Union of Thematic Oriented Approach + Object Oriented Tool as a contribution to Computer Programming disciplines.*Thematic Oriented Approach together with Object Oriented modeling contributes to curricula integration under complex view. From sophisticated modeling principles till little programming details, or even, high abstract values as the insertion of informatics on human life, all can be treated together in an introductory computer programming discipline.

*On the integration of basic disciplines on fresh man curricula under thematic Oriented approach.*Thematic Oriented Approach, supported by Object Oriented Modeling Tool, promotes easy and harmonic integration between several basic disciplines, as introductory computer programming, information systems modeling, numerical methods, statistics methods, physics and maths. The abstraction principle aids to develop several project versions creating reusable knowledge.

*On the Thematic Oriented Vision as an Open Pedagogic Proposal Looking to Tecno Careers New Profile.*Integrated, open, or even, Complex Vision on education contributes to new professional profile and to alter professional life, under globalization demands. Integrative tendency is an important pedagogic option because it considers all educational aspects together changing pedagogic axis to human development process. And this is a high abstract pedagogic directive that is welcomed regarding future life at earth.

THE EVALUATION OF HIGH-RISE BUILDINGS IN ISTANBUL

Çiğdem Eren[1]*, Ayşe Tütengil*[2]

Abstract — *This paper aims to propose a model to be implemented in the analysis of the qualitative and the quantitative aspects of high-rise buildings and the evaluation of existing high-rise buildings to define objectives and strategies considering the conditions for today and the future. The computer-aided approach adopted in the model is based on the implementation of Microsoft Excel enables flexible, explicit and dynamic flow of the relevant information required for evaluation. The proposed interactive evaluation model comprises two major stages; implementation of an evaluative method for the assessment of the high rise buildings in relation to a preset criteria, implementation of an utility analysis method for the evaluation.*

INTRODUCTION

The aim of the study is to propose a model to be implemented in the analysis of the qualitative and the quantitative aspects of the high-rise buildings and the evaluation of existing high-rise buildings to define objectives and strategies considering the conditions for today and the future. Istanbul has been chosen for the case study for being the most active and most criticized region in Turkey for its high-rise buildings, being the most populated city of the nation primarily due to domestic migration; and possessing a remarkable cultural heritage. (Figure.1)

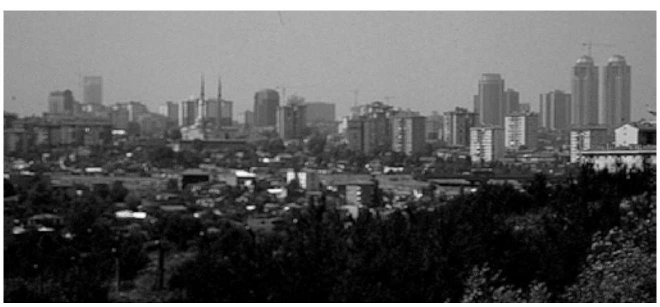

FIGURE. 1

The proposed evaluation model comprises three major stages:

- Implementation of an evaluative method for the assessment of the high rise buildings in relation to a preset criteria,
- Implementation of a utility analysis method using Microsoft Excel for the evaluation of the high rise buildings under consideration and,
- Definition of objectives and strategies considering the conditions for today and the future.

HIGH-RISE BUILDINGS IN ISTANBUL

High-rise building constructions involve many complex problems; requiring high technology use, need of considerable knowledge and experience through serious discussions and decisions at design level. In developing this important and essential building type in Turkey, initial problems faced are how to control such projects according to different side effects and how to identify and evaluate its advantages and disadvantages [3].
Therefore the following specifications are used for the definition of high-rise buildings in various countries (Table I):

TABLE I

Country name	Buildings defined as "high-rise"
Germany	22m.height and over
U.S.A (Massachusetts)	21m.height and over
U.S.A (San Francisco)	23m.height and over
Britain	28m. height and over
Switzerland	25m. height and over
Russia	9 floors and over
Austria	10 floors and over
Poland	12 floors and over
Hungary	11 floors and over
Czechoslovakia	Shows variations according to buildings around the neighborhood
Mexico	30m. height and over
Turkey	10 floors and over

Slender buildings like towers and minarets reaching the skyline have a long history in Turkey, but multi- storey and multi-functional buildings started to be developed as recent as 1950's. Istanbul, which is one of the most important cities

[1] Dr. Çiğdem Eren, Technical University of İstanbul , Faculty of Architecture, Taşkışla Taksim 80191, İstanbul, Turkey, cigdemeren2000@hotmail.com
[2] Assoc.Prof.Dr. Ayşe Tütengil, Technical University of İstanbul , Faculty of Architecture, Taşkışla Taksim 80191, İstanbul, Turkey, tutengil@sim.net.tr

of the world, with its natural and historical beauties rapidly began to grow in size and population in 1950's due to political and social reasons. The technical and financial deficiencies of local authorities added further problems on the undisciplined growth in industrial, commercial and servicing functions, hence the city's development became extremely unplanned and disorderly. The high prices of land due to heavy demand for construction areas, which has already been developed, caused the horizontal expansion of the city in an uncontrolled and unstoppable way. The constant decrease in land, increases in price, speculative pressures brought about a dense use of land through development of high-rise buildings, which added further functional, environmental and constructional problems on the existing city pattern. Particularly the inefficiency of existing control plans and constant changes made on them necessitated planning and development of high-rise buildings.

FIGURE. 2

After 1985 high-rise buildings became status symbols, which started to mushroom around Taksim - Gümüşsuyu - Maçka, Beşiktaş- Levent - Ayazağa, Mecidiyeköy - Zincirlikuyu, Ataköy-Zeytinburnu regions. (Figure.2)

DESCRIPTION OF THE EVALUATION METHOD

.In order to highlight the qualitative and the quantitative values of high-rise buildings a chosen utility analysis method is implemented. The aim of the proposed utility analysis method of evaluation is to guide the decision making process related with future developments. The program Microsoft Excel is adopted in the method. Using the means of a computer makes it possible to archive data about high-rise buildings properly, to work with tables having compatible format and to achieve results rapidly and correctly. The created evaluation files are flexible, explicit and dynamic [1].

The advantages of the above mentioned evaluation method could be summarized as follows:

- Value criteria for preservation are made explicit.
- By using the weight assignment method during the evaluation process, the relative importance of initial criteria and expert opinions are properly reflected during all stages of implementation.
- Initial decisions can be revised by reconsidering the weight assignments of various factors if and when necessary.
- Results of evaluation, due to its explicit structure, can be easily reviewed and checked by those who are outside the group of the decision-makers at any stage.

The proposed method is arranged so that it can evaluate each high-rise building individually by reflecting its intrinsic value. The method with its aforementioned explicit, flexible and dynamic structure provides a proper basis for the evaluation of the high-rise buildings. The described evaluation method can be summarized in the following stages:

- The development of a system of objectives by the experts, which come under the five headings:
  - Architectural and cultural objectives;
  - Technical objectives;
  - Environmental objectives;
  - Environmental control objectives;
  - Financial objectives.
  -

These objectives, in turn, have their appropriate sub-objectives, which are listed in Table II, III and IV, Column 1.

- A priority assignment method has been used in connection with the first stage of the synthesis. Weights are assigned to the sub-objectives to reflect their relative importance. (Table II, Column 2-4). Here, the experts assign a value on a scale of 0 to 10, for each sub-objective on Table II, Column 2 of the program. Through Microsoft Excel, to accelerate the effect of the most important sub-objective; related weights are reorganized according to the adopted Churchman Ackoff method (Table II, Column 3) [2]. The last step of the weight assessment process, through Microsoft

Excel weights are standardized and real values for evaluation are determined (Table II, Column 4).

TABLE II

PRELIMINARY ANALYSIS

OBJECTIVES	SUB-OBJ. WEIGHT 1. STEP	SUB-OBJ. WEIGHT 2. STEP	SUB-OBJ. WEIGHT 3. STEP	WEIGHT OF EXPERTS						EXPERTS TOTAL WEIGHTS

4.2 SOLAR CONTROL	4	7	1,17	4,0	1,0	0,5	3,5	0,5	0,5	10
4.3 NATURAL VENTILATION	2	2	0,33	4,0	1,0	0,5	0,5	0,5	3,5	10
4.4 WIND MOVEMENTS IN & AROUND BUILDING	4	7	1,17	3,0	3,5	2,0	0,5	0,5	0,5	10
4.5 ORIENTATION OF BUILDING	2	2	0,33	4,0	0,5	4,0	0,5	0,5	0,5	10
4.6 COLOR OF BUILDING	2	2	0,33	4,0	0,5	3,5	0,5	0,5	1,0	10
5. FINANCIAL OBJECTIVES										
5.1 COSTS	7	22	3,67	2,0	2,0	0,5	2,0	1,5	2,0	10
5.2 SALE & REVENUE VALUE	7	22	3,67	2,0	2,0	2,0	1,5	1,5	1,0	10
5.3 FUNCTIONAL VALLUE	7	22	3,67	4,0	0,5	1,5	0,5	0,5	3,0	10
TOTAL		599	100,00							

Likewise the experts from different disciplines (architect, structural engineer, town planner, mechanical engineer, electrical engineer, interior architect) have been subject to a similar weight assignment to enable them to evaluate sub-objectives according to their disciplines (Table II, Column 4-9). Weighing the expertise of the participating experts requires the partaking of the total of 10 points among the experts in regard to their fields and its probable relation to the sub-objectives. This completes the preparation procedure of the evaluation method.

- Weights determined during the preparation process are then transferred to the Table III, where each expert contributes his/her field of expertise followed by the evaluation of each sub-objective on a scale of 0-4 (Table III, Column 2).

TOTAL SUM	2491,9					

DESCRIPTION OF THE SUB-OBJECTIVES

During the application of the proposed method the experts in regard to the relations with various attributes of the entities evaluate sub-objectives. [1]

The relevant sub-objectives of the objectives system can be listed as follows:

1. Architectural and aesthetic objectives

1.1. Artistic value: Artistic value can not be defined by any objective criteria, though it is a long and intriguing process of formation though accumulated knowledge and common wisdom gained by humane expertise. Notably, the design approach for a building and its integrity with its built and natural environment as well as its location within it are the main constituent factors for this formation.

For the determination of the artistic value, factors such as its relative comparisons with building of the similar characteristics and spatial organizations should also be taken into account.

1.2. Aesthetic value: Aesthetic value is based on a number of complicated factors, such as, variety of elements, rhythmic effects, different materials and pattern, play of matte and reflective surfaces, play of light and shadow.

There is no objective method for the determination of the aesthetic value, it can be only established by a comparative analysis of several different buildings by the experts

1.3. Association with important historical events: Important buildings have a documentary value, since they reflect the trends of the eras in which they were completed. A high-rise building could be constructed to symbolize the beginning or the end of a significant historical event. Many buildings are also the most reliable witnesses of the political, social and cultural aspects of the times in which they were built.

1.4. Work of a well-known artist: A historical or contemporary work of an architect, who is master in design approach, has a remarkable value, which should be considered in the overall valuation.

1.5. Scarcity value: A high-rise building, which has unique characteristics such as a path-breaking and innovative approach in design and construction, should be considered as symbol of the development.

1.6. Facade value: Surface treatment reflects the scale and important lines of a high-rise building. Articulation of the building, cladding material, material changes, play of light and shadow, reflections on the surface, color and ornaments are some of the important factors in the ultimate formation of the visual effect of the façade.

1.7. Spatial organization value: A building is a synthesis of exterior skin and interior organization. Interior design also includes decoration, furniture system, sculptures and other works of art. Other factors, such as allowing maximum design flexibility in the interior space for technology upgrades in the future must be taken into account by the determination of the spatial organization value.

1.8. Historical value: Buildings are lasting memorial with their locations as well as their capacities to reflect the urban and social history of the times they were built.

2. Technical Objectives

2.1. Technical innovation value: A high-rise building can be innovative in its design approach, construction and structural system and become the symbol of a new development.

2.2. Constructional value: The valuation should also cover beside aesthetic appeal technology and construction elements.

2.3. Earthquake resistance value: Turkey, especially Istanbul, is situated in a potential earthquake zone; therefore the structural systems of all high-rise buildings should conform with the earthquake design criteria to withstand any deformations to be caused by the possible future earthquakes.

2.4. Fire control value: The initial objective should be to take every precaution to prevent fire incidence. Sprinkler systems, smoke exhaust systems, pressurized stairwells, dedicated recall firefighter elevators, emergency exits supported with a sophisticated fire command center are the main elements for these precautions.

2.5. Lightning protection value: High-rise buildings should accommodate strong lightning conductors for lightning and similar natural causes.

2.6. Structural system value: In the selection of the structural systems for the high-rise buildings, time and cost calculations are the foremost priorities. The structural systems should provide the necessary lateral resistance to the forces of wind and earthquake, while supporting the vertical loads.

2.7. Legal aspects and regulations: Various authorities from the beginning of the design level to the end of construction process should enforce controlling mechanisms. The inefficient legal procedures and regulations may cause serious problems. All high-rise buildings should be evaluated both under the city and building scales.

2.8. Mechanical transportation value: Elevators and escalators should be planned and constructed by using high-tech, considering the building's mode of function and the density at peak hours.

2.9. Soil properties value: The soil characteristics and the problems of bearing capacity of the ground at the building site should be checked with soil examples taken from the site and with their appropriate laboratory tests. The evaluated input from these tests will help deciding the structural system.

2.10. Security value: The quality of a newly completed high-rise building should reflect proper security measurements. The computer-controlled environmental safety and security systems, such as interior automation control (air conditioning, elevators etc.), security measurements (alarms, detectors, visual control systems etc.), emergency plans for fire, earthquake, accidents etc. are the main elements of the safety and security measurements.

2.11. Air transport security value: Location of high-rise buildings can endanger air traffic. Due to security reasons high-rise building projects must be developed outside flying routes and airport borders.

3. Environmental objectives

3.1. Environmental landmark value: In the geographic, historic and economic environment a high-rise building rises as a focal point of the skyline. They are visible landmarks and dominate the skyline.

3.2. Environmental symbol value: With the historically accumulated public interest a building may have a special aura hence becomes a symbol of its location. With their impressive appearance great buildings become symbols of their city.

3.3. Environmental group value: A high-rise building can be an important element in defining the urban streetscape or a square. It may provide continuity or define a boundary in the skyline.

3.4. Skyline value: Historical developments and general characteristics of a city define its skyline. The protection of Istanbul's natural and historic skyline, which goes back to hundreds of years, is very essential. The placement of high-rise buildings should take the existing skyline into account and should be carefully decided with various skyline studies carried out from different viewpoints of the city.

3.5. Density value: The additional problems related with the infrastructure (traffic, electricity, water, sewer etc.) must be identified at project level. The density must be decided according to existing characteristics of the region.

4. Environmental control objectives

4.1. Microclimate value: Elements like the buildings' shadow effect and period, air corridors between buildings, prevention of sunlight that effect the microclimatic value of the building should be solved at design level.

4.2. Solar control: The effects of high-rise buildings to neighbouring buildings and open space should be checked from the health point of view. Sufficient sunlight should be available during the day. This is especially important for the solar energy facilities if and when they are available.

4.3. Natural ventilation: Suitable positioning of openings can improve the natural ventilation and lower air-conditioning costs.

4.4. Wind movements in & around building: The positioning of a high-rise building should minimize the unwanted air turbulences within the surrounding area.

4.5. Orientation of the building: The orientation on the site should serve functional as well as aesthetic purposes. Suitable positioning can improve sun shading, which results in lower lighting, heating and air-conditioning costs. A strategically located high-rise building can be visible from every axis of the city. The design should be determined primarily through conformity with technical specifications such as shadow restrictions, positioning the building to minimize heat lost on the northern face. Adjacent buildings and views of the city are also vital factors to be considered.

4.6. Color of the building: The color and the material used in the exterior surfaces are important decisions for the building. Selection of the color should be based on environmental conditions such as the existing city pattern, far and near appearances, silhouette and building type.

5. Economical objectives

5.1. Costs: There are elements that can dramatically effect the structural unit costs. These are mainly the use of cladding and interior materials, the selected structural systems, as well as the number of floors, method of transportation of materials, construction equipment etc.

5.2. Sale and revenue value: The market value of the building indicates its sales or interchangeability value. The revenue value, on the other hand, is the income obtained from rental or entrée fee etc.

5.3. Functional value: The functional value bases on the composition of several spaces, the determination various functions and flexible spaces.

CONCLUSION

Istanbul's topographical and historical location makes it necessary to evaluate the high-rise buildings on different scales. The potential problems must be discussed both under city and building scales. The city's constructional state and the territories should be examined for achieving the targets for a healthy city life with high-rise buildings.

Istanbul's structural status and existing high-rise buildings should be evaluated and objectives and strategies should be defined by considering conditions for today and for the future developments. Especially in Istanbul, high-rise building sites must be evaluated, based not only on the area they cover but with the surrounding environment data as well [3].

A healthy territory research should be carried out to define

- The restricted zones for high-rise buildings,
- The zones that are permitted whether certain conditions are met,
- The zones that high-rise building constructions may be encouraged.

Istanbul's natural, cultural and historic specifications should be preserved within these definitions.

Proposed model is designed to evaluate the high-rise building in Istanbul and through the implementation of the utility analysis method of evaluation; objective values of the entities under consideration were made explicit in order to determine the guiding principles in future decisions. Within the framework of set objectives for evaluation, the findings related to architectural analysis of the buildings and available data related to them can be used as guidelines for the future developments.

Chaos, Cognition and Cyberculture – an environment

Marcos Luiz Mucheroni[1], Ro Yih Ching[2] and Cairo Gomide Jr[3]

Abstract — *The representation´s concepts of knowledge and semantic databases can be applied to object orientated concepts to knowledge, such as, objects and classes of information in properties representation and relationships of them. This work is an environment project to provide applications of using knowledge-based data, organized in Content Management and user interface in an self-organizing mode. It includes considerations about knowledge, networking and formats. There are brief theoretical considerations about knowledge and intelligence, to justify the need of this chaotic system, described soon afterwards. The data is put in matrix model and used the algorithm SOM (Self Organizing Maps) in a syntax for the representation called RDF (Resource Description Format - an extension of MCF) in XML (EXtensible Markup Language) and a vocabulary (or descriptors group) for the Internet. The use of the language Java will give support for the metadatas models and interoperability among several patterns. Measurements with 100 virtual users were made.*

Index Terms — *Chaotic database system, knowledge-based, cognition.*

1 - INTRODUCTION

Most of the theories and humans believes (the believes are nearer to us than what is imagined) are codified by a cultural compound creating a semantic set that includes its language and its knowledge, as well as the language is related to the code, knowledge is related to information but the intelligence is something superior capable to releasing men from these conditioning and build something really new, and this is what is called here current intelligence, in narrow connection with Pierre Lévy´s [14] concepts of actual (but not the real) opposing the virtual.

Language, codes and codification can be considered as fundamental part of what called reality, but this reality is different from the abstract reality that it is more related to the knowledge. Of course, we have an entire philosophical discussion here on reality and knowledge. In the practical sense in this work, knowledge is used as Levy´s definitions: “Knowledge, values and tools transmitted by the culture...” , “But always...of a dialogue or of a multi-dialogue, real or imaginary” and “"we will end up in the instruments... it is impossible to exercise our intelligence independently of language, vocabulary and systems of signs” [13].

In this subject, we speak about certain levels of abstractions and of realities, or more concretely as defines by Pierre Lévy [13], intelligence levels linked at certain levels of technologies, but like he says technology is "classification to help to locate the poles", what can be made not only in relation to technology, but also to the productive development, the complexity of the language (orality levels, for Lévy only two) and why not, the level of elaboration that get together man and nature as a complex life, that it is our thought.

Apprenticeships different from the man allowed different orality forms, code, languages and thought styles, and for its time they generated differentiated forms of storage and classification of the information. For the current cognitive sciences [17] they are called of code strategies [1] and but they also present the result that the conscience no resulted of the language [3], and many errors and fallacies about consciousness and intentionality [5].

But this doesn't mean that language and code are not important, and it is possible to maximize its potential in the information age, we will need a better understanding of nature intelligence and technological knowledge in matter, and the human concepts and its limits in general.

Recent researches give some hints that certain mechanisms of the brain work in a self-organizing way [10].

The elaboration in this first part of the work is to build a digital system of easy access and of great interconnection capacity for networking, and for that is necessary to choose a storage format, proposed with the name Small Embedded of Data Center Environment “Cognitio” (SEDEC).

The system uses feedback information from its users to change its representation about the data (e.g., in digital library: about of authors, index terms, and documents), is possible the users to change its representation of data, index terms, and documents over time, so this include cognition on the system, so “Cognitio” is the name. Many systems are developed using a similar model of three-layer network of queries [12] also, index terms, and documents and others use modified Hebbian learning rule [7] which was used to reformulate probabilistic information retrieval [19].

While the above systems represent information retrieval applications in terms of their main components of documents, queries, index terms, authors, etc. other researchers have used different neural networks for more specific tasks. The “embedded” is because any applications will be included in target system (e.g. digital library).

Mind, cognition and consciousness

Good part of the contemporary knowledge leaves concrete for the abstract, as if the theory was the arrival point. But the new scientific paradigms make a more complex way, they leave the abstractions to elaborate other abstractions, worst, because we always have multiple theoretical points of departures and they turn the theory arrival points, while the reality, even if not completely understood (the real intelligence) it is always closer of the human problem than the abstraction.

It is right that the knowledge comes from reality of the real (not actual), but the real has different reality levels, for simple example, four apples are 4, but what is 4? - an abstraction and a sign! Then remove the quantitative factor: an apple will be a code to indicate a group of complex qualities of certain fruit, in agreement with the intelligence of who hears he translates it in a certain representation level, or abstraction level.

Cognition is defined in the dictionaries as: "the action or process of knowing in the widest sense; specifically, an intellectual process for which there is a knowledge earnings, of perception or ideas" and in a certain way is quite compatible with the Hebbian neural learning systems [7].

But, is the mind that translates the world of particles and waves in a world of colors, sounds and smells, how? If we know the answer that can make the machines imitate our human mind's processes and we can put them to aid our work.

The psychology, philosophy, information's theories, the cognitive sciences and the neurophysiology tried this to answer while the artificial intelligence initially tried its own road, but today its is closer to this because of the Internet and the development of a cyberculture.

It is possible to simplify move the discussion foreward, defining mind as:

Mind = cognition + consciousness

where: the cognition is omnipresent in the nature, and consciousness is a natural phenomenon, present in the man as subjectivity.

But the remaining question is: "How do brains work?" The studies of technical tools [18] and others enables us to model brain functions that transcend the present limitations of computational or schematic models, and go to the domains of non-cartesian concepts of consciousness emerges, any insight was arrived in past century: the cycle of "action, assimilation and adaptation" [18], "Mind is the structure of behavior" [8] or the ecopsycology of the "an affordance ... of an object offers what it does because it is what it is" [6].

Knowledge in technological information age

As well as the primary orality and the writing they generate a relationship different with the knowledge, the cyberspace supports intellectual technologies that enlarge, they utter and they alter many human cognitive functions: the memory (databases, hipertexts, digital files [numeric] of many types and orders), the imagination (simulations), the perception (sensor digital, telepresence, virtual realities), the reasonings (artificial intelligence, neural networks or other model of complex phenomena).

The actual cyberspace is Web, but the Web is still very rigid, it offers a group of options but the user's possibility to create their own ones and stiller, of to show his intention and to ask the machine that helps him in the development of his insight is still a distant possibility.

The elaboration in this first part of the work is to build a digital system of easy access and of great interconnection capacity for networking, and for that is necessary to choose a storage format.

There is a large number of different formats of different kinds of information can be stored, but knowledge includes more general information such as: voice, images, songs, feelings, or simply a conversation with a friend to be registered as a note or release. Therefore the best format doesn't exist nor one best piece of software to access the data in general the document is served as different information source about a number of different formats. Like this we don't intend to define an unique format of input, but a concise formatting that gives the maximum flexibility to the user that makes the consultation as a possible source. It is intended besides to allow, at the interface level, that the user organizes his search in a personal way, and the group of this search will be in chaotic mode using self-organization.

Chaos and self-organizing information

The chaotic mode is not disarranged or disturbed organization, or its organization named self-organizing, it is a complex way of organization and it is compatible with a new science: Chaos Theory.

This theory is specially applied to non-linear system in different techniques, one technique is to detect special singularities named "atractors" in time series analysis.

In this work the concept of special method of self-organization named SOM (Self-Organizing Maps) is use to search words and texts, tags and special words in Web environment and special data in Database Content. Metadada in the environment compounds this Data Content.

Lin [15] adopted a Kohonen network for information retrieval. Kohonen's [11] self-organizing feature map (SOM), which produced a two-dimensional grid representation for many features, was applied to construct a self-organizing (unsupervised learning), visual representation of the semantic relationships between input documents. Many type of SOM algorithms is being built, but a special algorithm was made for to searching in the WEB, and is named WEBSOM [9].

2- AN ENVIRONMENT – THE SEDEC

Many companies, organizations and several enterprises that use digital information that use on-line digital systems and are now upgrading their systems to WEB systems [16] or beginning a new Web system, e.g. e-commerce system.

But now any new characteristics are happening and new problems are detected:

- a lot of information is on-line in the net, but without patterns and a lot of duplicated "lineal" information (e..g. letters, emblems, gifs, images)
- many light devices are available (e.g. Palms, PDAs.), but the connection with information is difficult.
- there is a lot of memory available in the net, but the security and administration is critical.

The first problem is standard and the new concepts that discussed more and more this problem to search more and more patterns, but the reality sense is use any special patterns in an special box named container. This concept appear in programming Java language in connection to components, that is the element that add to a container are tracked in a list.

The second, lineal information is stored in two types of documents: Content Management to typical texts, emblems, etc. and Backup/Reporting to schedulers, securities info, the copies or other needs. This information is related to Content Database, that is, the metadata where any patterns is related and is provided to add or exclude any field, tags or labels to this metadata if the any point manages. One very fast station control this Content Database, and two others station treat small (e.g.text) and big data (e.g.images).

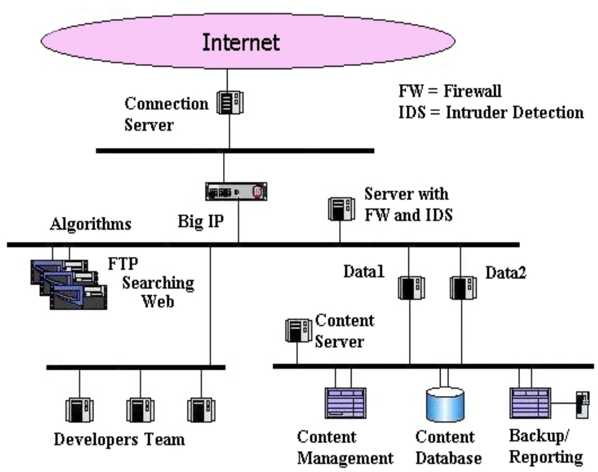

FIGURE. 1 –A SEDEC “COGNITIO” ENVIRONMENT.

The security problem is solved using Firewalls (FW) and IDS (Intruder Detection Systems) in a system named in-depth model, because track each connection traversing all the firewall’s interface to make sure they are valid. As FIGURE 1 shows, is a partial system because it lacks a system of applications.

Special devices: downloads, search and WEB

The special effort for this system is the use of small Data Centers geographically separated, that is, distributed, and this result new problems: downloads, searching and WEB organization. Other problem cited later, is the WEB offers a group of rigid options and doesn’t has flexibility for user search his proper paths.

The special device Big-IP is to perform local load-balancing (LLB). The machines provide load-balanced IP address to the Internet and distribute incoming request locally based on any server’s availability and response times.

For primary stage in this implementation, we installed two device named Data1 and Data2 in the same place, for academic reason, but in application target we think implementation in data centers distributed and geographically separated. Three primary facts drove our goals: ease of management, low costs and democratizes the resources. The main goal is distributed data centers.

Any organization’s requirements was evaluated: trace ability to a common problem, a document is commonly the final goal of activities in business and research but has many complex documents (multimedia), documents as corporate or group memory and others.

A common technique in linear system is to use linear, random or stochastic mapping for information organization to searching and sorting, included: sorting method (bubble or shell, for example), neural networking and other. But ordinary people, which are unaware of these methods, have a proper way to organize information, that realization motivates the development of self-organized systems.

Three software devices are proposed: WEB, FTP/ Downloading and Searching. Current FTP is made in software, but in target system will be in FPGA devices.

An important requirements is the management of different formats, for this we determined that the Content Management Application (CMA) should reside wholly in staging. The use of XML and the concepts of RDF (Resource Description Format - an extension of MCF) in XML (EXtensible Markup Language) and a vocabulary (or descriptors group) is done to solve these problems.

Searching WEB using the SOM algorithm and special search (e.g. using descriptors group), guarantees good results, but he main advantage is that distributed centers can have searches self-organized done in each user's owner formatting. The final implementation will provide the own interfaces. Separate users (or servers in goal application) at each location handle all available devices and backups/reporting, or documents with Content Management.

In the heart of this problems is a SOM (self-organizing algorithm), and initial evaluation is to simulate this devices environment, tests and evaluations they can prove the need that these devices are made in hardware, in this case, we will opt for algorithms in FPGAs.

The self-organizing map (SOM)

The self-organizing map (SOM), developed by Teuvo Kohonen in the decade of 80, present a map topologically based in the cerebral cortex. It is known that the brain of the most sophisticated animals has areas that are responsible for specific functions. Areas exist, for example, dedicated to the speech, to the vision, to the motor control, to the sensibility, to the touch, etc. Each one of these areas contains subareas (each subarea map is responsible of the sensorial organ represented by the map). For example, cortex auditory map capture the different sound frequencies and cortex visual map capture visual primitive characteristic, such as light intensity, orientation and curvature of lines [2].

As all the artificial neural network, the Kohonen's map are formed by a group of simple elements, called neurons, organized in more complex structures, that work together: the net (or map). Each neuron is an unit of processing that receives incentives (of out of the system or of another neurons), and it produces an answer (for another neurons or outside of the system). Just as the neurons of the brain, the one of the neural network are interconnected itself through ramifications which the incentives are spread. Every entrance is connected to all the output neurons.

A Kohonen's model is based in a competition of the information representation presented in the input data by output layer neurons. Choose a winner neuron, this is readjusted to answer still better to the received incentive. Inside of this not supervised model, not only the winner, but also its neighbors (in a physical sense) are adjusted.

Two important aspect of data are developed in SEDEC: storage, management and organization using metadada in Data Content Management, and a second aspect, the relationship between related data for intelligent search and research using SOM algorithms.

3- The environment (SEDEC)

In first aspect (Data Content Management), is important the use of RDF (Resource Description Format) and XML.

Starting from the model MCF (Meta Content Format), RDF created is a Formal Model of Data and it can be defined like "Architecture Components to Support Metadata Interoperability", with a transfer syntax based on XML, being this a Syntax human-readable and machine-processable, or be allowed each description community (in our case the user) to define its own semantics, without the need of an only pattern for all, like this she provides a structural interoperability. This model uses graph addressed and a tool (Resource) that is described through a collection of properties (Property.) call of RDF Description, where each property has a Property Type and Value. Through the property Type the resource obtains a value. URI is a value constant defined using strings. The FIGURE 3 shows RDF:

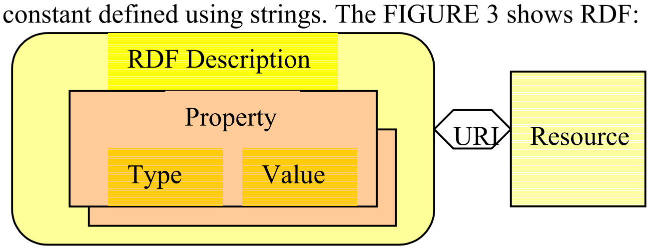

FIGURE 2 – GENERAL RDF DESCRIPTION.

This neighborhood region can assume several different formats. Although the square format is the most common, the neighborhood area can also present, as in the FIGURE 3, the form of a hexagon or circle (gaussian). The definition of the most appropriate format depends on the problem and the data's distribution.

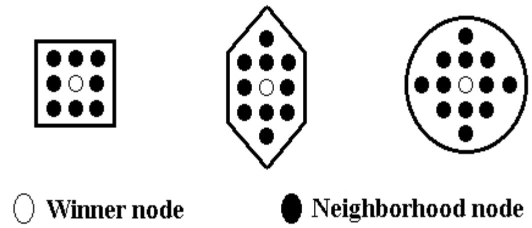

FIGURE 3–DIFFERENT FORMAT OF NEIGHBORHOOD

To understand how the algorithm works, consider the follow input data, the weights and the output neurons in the FIGURE 4. For each input data, has a weight, and each input data is linked to each output neuron, so W_{ij} defines the weight, where i represents the entry X and j the output neuron [4].

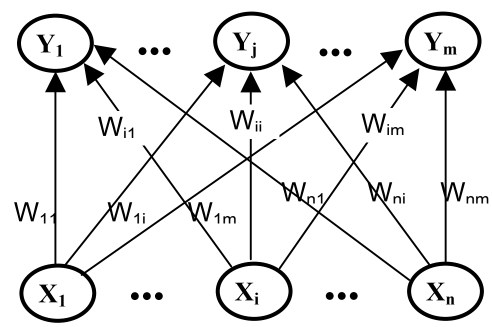

FIGURE 4 – EACH INPUTA DATA X IS CONNECTED TO OUTPUT NEURON Y.

The neighborhood region, or topology, of self-organized map, can be square, hexagon, circle, like in the FIGURE 3, for a didactic reason, a lineal topology will be used, shown in the FIGURE 5. The nodes (or neurons) they are represented for *, and the winner node for #. The rays of action of the winner node is illustrated by symbols: {}, (), [].

* * * {* (* [#] *) *} * *

{ } R = 2 ( ) R = 1 [ ] R = 0

FIGURE 5 - LINEAL TOPOLOGY .

Consider a weight Wij, an input vector Xi, a group of output nodes Yj and the learning rate α that can be modified by each group of entrance vector, so step-to-step:

0. Initialize weights Wij.
   - 0.1. Set topological neighborhood parameters.
   - 0.2. Set learning rate parameters (α).
1. While stopping condition is false, do step 2-8.
   - 2. For input vector x, do step 3-5.
     - 3. For each j, compute:

$$D(j) = \sum_i (W_{ij} - X_i)^2$$

4. Find index j such that D(j) is a minimum.
5. For all units j within a specified neighborhood of Yj, and for all i:

$$Wij(new) = Wij(old) + \alpha[Xi - Wij(old)].$$

6. Update learning rate.
7. Reduce radius of topological neighborhood at times specified.
8. Test stopping condition.

The learning rate α is a slowly decreasing function of time (or training epochs). Kohonen indicates that a linearly decreasing function is satisfactory for practical computations; a geometric decrease would produce similar results [4]. The radius of the neighborhood around a cluster unit also decreases as the clustering process progresses.

The formation of a map occurs in two phases: the initial formation of the correct order and the final convergence. The second phase takes much longer than the first and requires a small value for the learning rate. Many iterations through the training set may be necessary, at least in some applications.

4 – RESULTS AND CONCLUSION

Before going live with the initial infrastructure, we realize tests to verify that it met necessary performance requirements and to remove any possible bottlenecks.

Testing simulating up to 100 simultaneous virtual users in intranet (the most interesting is use modem but for the time being we don't have this possibility), using a set of virtual users to travel specific paths of varying lengths through the site and download documents and data of various sizes and formats.

The Table 1 illustrates, the primary resources linear and primary resources used in self-organizing model, using transfer rate of the 100 Mbps in FastEthernet, the storage progression (in Mbytes by minute) for two machines Data1 (simple texts) and Data2 (images), the storage in minutes is:

TABLE 1

Storage	1 Virt Users	5 Virt Users	50 Virt.Users	100 Virt.Users
Data1	33.4 Mb	9.45 Mb	4.77 Mb	2.12 Mb
Data2	33.2 Mb	8.40 Mb	4.20 Mb	1.86 Mb

The conclusion is there are many specific methodologies for developing Web and popular Web-based application, in our work is user-based in an approach self-organizing. The use of XML and Java (or C#) languages in connection with RDF formats implements the interoperability among different format of data.

ACKNOWLEDGMENT

The authors wish to thank Ro Yung Jia, and the teacher Dr. Plinio Vilela, of read and comments of this work, Euripides Foundation of Marília, and CAPES-CNPq Brazil to support this project.

DEVELOPING MINI-APPLICATION ON AUTOMATIC CONTROL WITH INTERDISCIPLINARY TEAMS.

Osvaldo Clúa, María Feldgen and Fabiana Ferreira [1]

Abstract *∞ . We developed an interdisciplinary course to train different engineering branches students in teamwork. We found that the application we asked to develop played a central role in the success or failure of the course. The application has to be complex enough to avoid a birds of a feather approach, but it has to be completed in a standard semester work time. We decided to follow a well defined project life cycle model as the axis to develop teaming skills and as an overall structure of the project. We used the TIDEE guidelines to develop teaming skills. As a result we found ourselves involved in a capstone design course with changing faculty roles as the project progresses.*

Index Terms ∞ Interdisciplinary experiences, soft skills, teaming, capstone course.

INTRODUCTION

The society perceives engineers to be technically competent with good math and science skills. However, society does not necessarily believe that engineers have good communication skills. In other words, the stereotype exists that engineers do not need to have good oral skills since they do not work with a lot of people. Clearly, this is an incorrect perception, but it nevertheless it exists.

Traditionally engineering education starts with a common core of math, science and basic engineering knowledge. This common background gives students a foundation for advanced studies in different but related areas of engineering.

Present time projects, on the other hand, require the cooperation among these different branches; but this cooperation is seldom addressed in undergraduate courses.

In order to overcome these teaming skills education deficit, we decided to transform an elective course in a capstone course which aims to show students the big picture of an engineering project. In the paper we present the project life cycle we use in the course, and how we use it as the integration axis of an interdisciplinary experience.

PROJECT'S LIFE CYCLE AND TEACHING MODEL

Modern project management departs from simple ongoing, repeated operations to a scenario where there is less certainty about anticipated outcomes. In more traditional project management, management procedures rely on centralized decision making and strict adherence to hierarchical authority.

In the teaching-learning arena, this management practice has its complement in the way traditional project assignment are conceived. The centralized decision making model is called teacher centered model [1], where every important design decision is made by the faculty (or following the faculty's ideas) and the student is expected to discuss and follow the faculty's directions. As a result, the experience of faculty leads generally to well finished and clean design, but the students are not allowed to follow their owns ideas and are in some sense "protected" from failure. Unfortunately, this way may also prevent students to develop an attitude of learning from their failures, which is considered a central path in building experience [2].

When adaptability and rapid response to change are called for, such as in the volatile present technological market, more complex and adaptive forms of organization and management are required, expanding considerably the degree of decentralization. Such an approach is sometimes called a systems approach [3]. An important aspect of the system approach to a project is the concept of life cycle. It is the basic pattern of change that occurs from beginning to end and that is similar in for all projects.

In the teaching-learning process, this management style can be mapped to a student centered model [4] where students are challenged to follow their own decision using faculty as consultants or facilitators of their design experience. To put the student centered model in action, some structure must be followed in order to achieve a measurable (or gradable) work. The project life cycle is a way of logically ordering the activities of the project and provides a control scheme for the assignment.

The project life cycle used as a model in the assignments had four phases: Conception, Definition, Acquisition and Operation.

For the Conception and Definition phases, students are asked to write a *Request for Proposal* to outline the idea and to state the objectives, scope, specifications and constrains. They answer the R.F.P. with a *Feasibility Study* which is used as a control point and a *Proposal.* As we will describe in the next section, these documents are used to develop some teaming skills. After writing the *Proposal*, teams are ready to enter their Performing stage and the Acquisition phase begin.

[1] Facultad de Ingeniería, Universidad de Buenos Aires. {oclua, mfeldge, fferreir}@fi.uba.ar

During this phase, students are asked to make a detailed project planning. They have to get the *User Requirements* describing what the user wants the finished system to be and do. Using this document, the final product will be evaluated as acceptable or not. It is a refinement of the R.F.P. and some changes to the original *Proposal* are included to test the adaptability of the teams. The *User Requirements* is used to derive another set called the *System Requirements,* where requirements are stated in technical jargon. By having teams write this document, we aim to develop a common technical language among specialties and to have each one understand the whole project. After writing the documents, the actual system design begins. We asked for the complete technical documentation depending on the specific project, including economic profiles such as return of investment, personnel training plans and maintenance procedures.

Depending on the complexity of the project, the availability of materials and the economic possibilities, the artifact has to be actually built in a whole, or some mix of simulation and building is asked. During a presentation, the team has to explain the operating procedures and identify maintenance issues and improving opportunities.

INTERDISCIPLINARY TEAMING

The project is developed using the TIDEE competencies [5]. TIDEE is an acronym for Transferable Integrated Design Engineering Education. TIDEE is a multi-university project supported by National Science Foundation. The TIDEE project focuses on the first two years of engineering design education in the state of Washington, and focuses on the improvement of both educational methods and materials used to prepare students for engineering design and practice. It can be described as an outcomes-based approach to engineering education and uses structured teams for learning and performing engineering design and is used as a model within the first and second courses. Using the TIDEE competencies as a guide, students learn to work together.

TIDEE identifies three major categories of competencies are required for team-based engineering design: design process, teamwork, and design communication.

The design process is further divided in six distinguishable elements. This elements are:

❖ Gathering information relevant to a need or opportunity,

❖ Definition of the problem establishing product requirements.

❖ Creating alternative solution concepts to address the requirements.

❖ Evaluation and decision making by analyzing options and selecting the ones best meeting requirements.

❖ Interpreting and synthesizing information and decisions an taking action to convert these decisions into deliverable products.

❖ Managing, evaluating, and improving design activity to use information and resources to achieve design objectives optimally.

The selected Project Life Cycle approach allowed to use these elements as control points by mapping then in the deliverables.

Teamwork is the second category of competencies required for effective performance of team-based engineering design. This encompasses capabilities associated with managing the personnel involved in a project to achieve the performance expected from effective teams.

Bruce W. Tuckman [6] stated that a group of people goes through well-defined developmental stages so as to becomes an effective team.

❖ In the forming stage, people act in a socially appropriate manner. They tend to focus on their territories and do things the established way.

❖ In the storming, team conflict begins. People are busy having differences and learning how to deal with them. They begin to gain confidence bringing up issues without going on the attack and blaming others. They also learn to listen to other's concerns without going on the defensive and counterattacking. Successfully dealing with conflict gives the team member a sense that they can bring problems to the group, and that the group will deal with them.

❖ In the norming phase people are able to put issues out for group consideration, and the group established ground rules and its own norms for acceptable behavior.

❖ In the performing stage the group can diagnose and solve problems.

To help students form effective teams and deal with the different stages in every class we scheduled some previous labs and lectures before they began with the project. We used the two first stages of the Life cycle to have teams pass the forming and norming stages.

Design-related communication comprises the third category of the TIDEE competencies for team-based engineering design. This category addresses capabilities associated with managing the information and its transfer during completion of a design project. A final presentation of the teams was scheduled to address this goal.

We did not use the TIDEE suggested scoring schema to asses the level of competency achieved.

THE MINI APPLICATIONS APPROACH

To avoid a sense of failure due to the complexity of a modern standard application, we choose to use mini applications that hopefully can be completed in a standard semester work time. In past experiences we used full blown applications asking students to develop only a part of it, but the winners or losers mood of the society induced a feeling of failure that prevented teams to evaluate positively what they learned. In fact, this is part a common underestimation of the present day everyday technology complexity.

To develop the subjects program, the mini applications have to be built using a distributed layered approach, using sensors and actuators at the field level, controlled by Programmable Logic Controllers (PLC). The PLC are integrated in cells communicated by a Fieldbus and some supervisory work is done using the Web in a conventional computer network. This basic structure allows to form teams with Electronic, Electric, Industrial and Computer Engineering students. Achieving a positive interdependence among different fields students is not easy and a carefully planned teaming set of activities was developed after some failures. An account of these activities is found in [7].

The chosen application is central to teaming efforts. It must provide a highly effective means of turning abstract ideas into project realities and difficulties, supporting a vast array of concepts to be taught and skills to be developed. In a similar effort, the Texas A & M implemented a Real-Time Lab, equipped with a model railroad system and five networked Linux-based control computers, two ActivMedia Pioneer class and two ActivMedia AmigoBot autonomous mobile robots, and 10 LEGO MindStorms robot kits [8] in order to excite student interest and provide an integration axis for different subjects. We choose industrial networks as the integration axis.

The industrial network technology applies the multiple advantages of the well-known OSI model [9] in automation. This fact is useful not only to explain the control concepts, but as a pedagogical tool. The cleanness of the layer model aids to understand the cooperation among different devices with well-defined functions.

The layered architecture calls for a well-structured and defined way of presenting the material in an undergraduate course. It also allows different abstraction levels, according on how the different engineering fields view the automation. This helps to integrate students from different field disciplines, in the same way that the industrial networks integrate different devices to deploy a complex field control, communication and control network. In this way, Industrial Engineers see the industrial networks as the integrating automation device they need for their processes, considering them at the application level and concentrating their interest in requirements' specification. Electronic Engineers are interested in sensors and actuators, so they deal with the physical and data link layers in order to interconnect the devices. Communication Engineers take care of the factory network integration and it connection with CAD, CAM, inventory and logistic applications. Software Engineers assure the work of layers 4 to 7, and integrate or develop applications in order to get the information properly presented to the user, e. g. using the enterprise intranet and the requirements specification. Control Engineers design the overall control and monitoring applications to meet the industrial specification.

As a grading objective, each student shall acquire the necessary skills to understand the system as a whole, and to implement a similar subsystem in her/his engineering field. And the instruction to the students is to convince the examiner in a public presentation that this objective is meet. This evaluation schema introduces students to the complex topic of public presentations, and faculty is required to do some preparation work regarding it.

The spectrum of mini applications used in the courses varies a lot. Some of the examples are automating filling facilities, bottling and boxing of fluids, hydroponic growing of industrial chili (used in cosmetics), water treatment and plastic packaging. Each one developed in an special environment with facilities, labor, communications and services corresponding to different places of Argentina.

CONCLUSIONS

By using Mini Applications, students become involved in problem management, instead the common approach of *closed* problem solving. This attitude emphasizes the fact that the design of a solution is only a stage in the project life cycle.

Understanding and interpreting the environment where the project will be developed plays a key role in the design process. students have to solve "secondary" issues as qualified labor availability vs. in house training or third part hiring of services vs. in house providing. By developing "parts" of a big project, these problems were neither identified nor addressed.

The rol of faculty changes during the different team stages. Initially, before the students are able to develop a shared understanding of what to do and how to do it, teachers have to play the rol of a project leader. As students gain control of the project, teachers become more a consultant and sometimes a customer to give some feedback ideas on functionality, structure and other project characteristics.

As every student centered experience, it implies a lot of work for faculties and a love it or hate it answer of students. Some of them argued they felt really identified with the engineering task and some of them were more comfortable with the "closed problem" approach and complained about faculty not having the problem well defined.

PRACTICAL CLASSES AND EXAMINATIONS ON BASIC ELECTRONICS LABS IN COMPUTER ENGINEERING

Mauro Conti Pereira[1,2], Fabrizio Leonardi[1,3,4,5], Marco Antonio Assis de Melo[3,6]

Abstract *— This paper describes how the Computer Engineering students at UCDB are motivated in lab lessons and exams, to get more out of lab experiments, to better understand future classes but also aiming at their professional life after graduation They have to try the experiments with simulators on their own, before lab lessons, coming more prepared and participating more effectively on them. A practical exam was devised to measure their practical proficiency in using lab equipments and in using their intuition to better analyze and understand basic electronic circuits. The help of teaching assistants (TA) was used in part of the practical examinations to speed them up, but in a structured rigid way to avoid variability of criteria by the TAs. These were developed over the years of the course existence, resulting in an increase in the students confidence and interest also for theoretical lessons, having encouraged their initiative and group skills.*

Index Terms — evaluation, laboratory, basic electronics, instrumentation.

INTRODUCTION

When the computer engineering course at UCDB was first created, we seeked a balance between hardware and software aspects in our students formation. Therefore, several classes were designed to have both theoretical and laboratory lessons, with these serving as motivation and reinforcement of concepts covered concurrently at the theoretical lessons. This happened to programming classes as well as those involving hardware, including classes for electricity, basic electronics, digital circuits, computer architecture, computer networks and notions of telecommunications, to name a few. Based on the authors work experience in design of digital hardware, commercial and scientific software development, and network infrastructure and management, it was clear the profile the an employer would look for in a future engineer.

Hence, it was necessary that the student didn't get to the end of the course by just being approved by passing written tests of what had been seen in the lab experiments, or by repeating one of the experiments. It was necessary to develop autonomy, self-confidence and experience to use lab equipments such as multimeters, oscilloscopes, function generators (FG), power supplies and the like. Mainly, it was important to develop the student's creativity to let him use it later with confidence in later classes, and even more, to let him practice his intuition in solving daily problems, like debugging computer network cables and NICs (network interface cards). For example, it is important for a computer engineering to recognize when a network is done according to cabling standards, at least to assess hired third party contractors.

The lab classes and evaluations were not only on the authors' experience from their students days at FEI, Georgia Tech and USP, but also from the exchange of ideas with professors from other schools, and from books like Leach [5], Malvino [4], Capuano & Marino [8], Chui [7] and other examples at the reference section. After a few years applying this methodology, we found out that USA universities also applied similar exams, as seen in Webster [1]. Every year new ideas are added, improving the exams and trying to correct any faults.

GENERAL DESCRIPTION

At UCDB lab and theory are part of the same class, with the same joint grade. To force the students make an effort at the lab lessons, the grades are defined in such a way that it is almost impossible to pass the course without learning the lab techniques. The passing grade without extra exams is 70%. Between 40% and 70% there is another test to complement the grade. Therefore, we forced 30% of the whole grade to come from the practical activities. If the students choose to ignore lab lessons, they need 100% on the theoretical part, which is highly unlikely. And for 30% of the practical activities, 10% comes from experiment reports and 20% from a practical proficiency examination.

Also, in the first lab classes they see basic concepts and learn to use simulators, like Electronics WorkBench (now renamed to MultiSim) [1],[5] or PSPICE [8]. From then on, to attend lab classes the student is required to bring a simulation of the experiment, done before the class. This

intends to make him try to understand the experiment before, bringing doubts, making better use of the professor and TA time at class, guaranteeing the completeness of the experiment during class time. We also intended for him to figure out that design problems can be debugged at a simulator, but a later practical assembling is crucial to handle practical problems, like assembling, noise, interference, etc. On the following week a report on the experiment has to be produced, one per bench, a team of three, with the grade emphasis being on the conclusions reached from the experiment.

For the remaining two thirds of the practical grade, a practical skill examination was created, so the student can show his abilities in using instruments and assembling basic circuits, as well as his qualitative understanding of the basic RLC and diode circuits.

It is not reasonable that a engineer graduates and could not, for example, use a multimeter to test on outlet voltage or not be able to test a network TP (twisted pair) cable, or still not being able to visualize the waveform of a modem or digital circuit. Flaws like that is what we try to avoid, trying to create an engineer who is not afraid to "get his hands dirty".

Simple instruments were chosen, more likely to be found on labs outside of universities. They were intentionally not automated by IEEE488 (or GPIB, general purpose interface bus, a network protocol for instrumentation), so the real skills of the students could be observed.

At its first edition, this exam proved to be too long to be given by a professor alone. Besides, there was a problem to keep the same level of exam throughout the long exam. The level should be the same for the first and last students, regardless of the teacher getting tired, or from one day to the next.

Starting on the second year of its application, the help of other students were used to speed things up. The TAs, or students from previous semesters who stood out, were used for the simpler parts of the exam, more direct and objective. The qualitative concepts were still managed by the teacher in charge.

WANTED KNOWLEDGE

The students receive a list of instructional skills to be done under supervision of a TA, shown partially on appendix 1, part of it was repeated on appendix2, and omitted here. The tasks are such as identifying resistors by color code, assembling series, parallel and mixed circuits, measurement of current, voltage and resistance, with both analog and digital multimeters, and the use of function generators and oscilloscopes. These are supervised and graded by the TA, with the teacher being responsible for the qualitative questions on behavior of circuits.

To let the exam have a rigid structured way, avoiding variability of criteria from one TA to another, a series of items to be checked was created. This list contains the 40 most common errors predicted to be made by a student, including connecting cables to multimeters (MM), and adjustments of MM, oscilloscopes and function generators, among others (refer to the appendix 2). A form to be filled by the TA was created, to better control and make grading easier (appendix 3). It contains the code for the possible errors on the lines, and the names of the students on the columns. Each wrong item takes 0.25 down the practical exam final grade.

To make it practical the students take the test in pairs, better described later on.

To check the competence of each pair, at each new pair the TA is oriented to randomly change components and adjustments of the equipments, like trigger, intensity, position, output level of the generator, ranges and so on.

As the years went by, suince the exam time is limited, the students started to practice in advance in the days before the exam, reviewing experiments and using the list of common mistakes as a study guide, as the minimum necessary, using the lab on its free off hours. There is no problem in letting them know this list, what will be asked, since what is asked is exactly what he is expected to know by the end of the semester, and later, after graduation. This way, we end up making them really get interested in using the lab off hours.

APPLING THE EXAM

As mentioned, to speed the tests up, the students are grouped in pairs, but with both being asked. If one of them does not know something, both of them loose the points of that item. With this, a solidarity atmosphere is formed, but without a weak student relaxing and leaving all the work to a competent friend. By the way, in 5 years applying this methodology, there has never been a non-homogeneous pair, of students with too different skills.

Three or four test benchs are assembled, with TAs applying the straight forward questions, and as each pair finishes, it waits to go to the teachers bench for the more subjective interpretative questions. Each TA writes down each pair mistakes on the form and randomly changes the settings and components for the next group.

The TA should not give any hints to the group, stopping them only to avoid mistakes that could damage the equipments, like burning a multimeter fuse, but still writing down this mistake. Initially this possibility was not foreseen, delaying the following groups because of having to stop for repairs.

Each pair has 20 minutes to execute all procedures, allowing up to 30 minutes but taking one point off in this case. After 30 minutes they should stop where it is to avoid exceeding the days reserved for the test.

The teachers bench is assembled with real or simulated circuits, like RLC in DC or AC, or supplied by square waves. Also half of full wave rectifiers can be used, having their behaviors analyzed and explained by the students. The teacher also asks for the identification of capacitors and diodes. After this, by changing the value of a component or characteristic of the injected signal, the group is asked to predict the behavior of the waveform. Or by showing a waveform they are asked what should have happened with the frequency or injected waveform or component values.

Each group is given different questions to different circuits, avoiding that in the waiting time a friend who has just done the test gives them tips.

The TA part accounts for 80% of the test, 20% is from the teacher, who assesses each student domain of the subject and gives the final grade of the exam test.

CONCLUSIONS

The use of simulators before lab lessons improved the use of the small time destined to them, but it was after the implementation of the described practical exams that we noticed a greater motivation of the students, even improving the learning of concepts given in the theoretical lessons. This way, the lab really reinforced concepts seen in theory.

The limited time of the practical exam forced the students go to the open lab to practice their skills and solve their doubts, increasing the percentage usage of the labs. The participation in class increased, as well as the students interest, and many students started to enjoy the practical aspects.

Although the effort was present in all experiments during the semester, it was at the end, when really asked for, that the students found out their capability of thinking on their own, increasing their self-steem and confidence.

We noticed a greater participation and pleasure in the all exam even by students who traditionally did not show interest or responsibility in solving lists of exercises, participating in theory classes or looking for a teacher or TA office hours to clear doubts.

By exchanging ideas with other university professors we felt the need to share these successful ideas on this paper.

The appendixes try to illustrate and help the accomplishment of similar ideas by whoever gets interested.

APPENDIX 1: DIRECTIONS THE STUDENTS (HANDED TO THEM)

Instructions:

The idea of this test is to measure your proficiency in using lab equipments, needed for the next semesters, as well as measure your intuition in understanding the behavior of some basic circuits. The student who fails an item lowers both students grades. Each wrong item counts for 0.25 of the total. You have 20 minutes to take all items. It can go to 30 minutes, but then one point will be discounted. At 30 minutes stop where you reached, the remaining is counted as wrong. The first 8 points are measured by a TA, the other 2 by the teacher, measuring your comprehension of some circuits. The TA will only stop you if there's a risk of damaging the equipment, but you still loose the item.

Procedures

The same as listed at appendix 2, the list of items to be done with possible common errors for the TA to grade. The list handed to student taking the test on appendix 1 obviously ommits the possible common errors.

APPENDIX 2: LIST OF ITEMS TO BE DONE AND OF RESPECTIVE COMMON ERRORS (FOR THE TA)

COMPUTER ENGINEERING – UCDB
BASIC ELECTROCNICS – practical evaluation

The student should know the items below. For each sub-item not known, decrease the total score.
The corresponding value is indicated on the table.

1. Identify the nominal values of 3 resistors (color code).
2. Assemble the mixed circuit in figure (1).

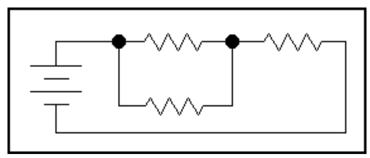

FIGURE 1

3. Measure R (resistance) and V (voltage) in each R with an AMM (analog multimeter).
a. tips should be inserted correctly in the MM (common=black, V/R red).
b. in AMM use the best possible range (with the tip in the middle of the display).
c. to measure resistance, R should be isolated from the circuit
d. at each change of R range, adjust the 0 (tips shorted).
e. read R multiplying the range position
f. read V in parallel to the element.
g. at each change of range of V, SHOULD NOT adjust 0 (tips shorted)
h. on AMM read in the proportional range, multiplying by factor 10,100, etc..

4. Measure I (current) in each resistor with AMM.
a. tips should be inserted correctly in the AMM (common=black, I(A) red).
b. in AMM use the best possible range (with the tip in the middle of the display).
c. I should be measured in series (break the circuit).
d. on AMM read in the proportional range, multiplying by factor 10,100, etc..
e. read the display value, with unity given by the chosen range (K, M...).

5. Measure R and V with DMM.

a. tips should be inserted correctly in the MM (common=black, V/R red).
b. in DMM use the best possible range (largest detail without exceeding the display).
c. to measure resistance, R should be isolated from the circuit
d. at each change of R range, it should NOT adjust the 0 (tips shorted).
e. read the display value, with unit given by the range (K, M...) (in DMM cannot multiply by the range)
f. read V in parallel to the element.

<u>6. Measure I with DMM</u>
a. tips should be inserted correctly in the DMM (common=black, I(A) red).
b. in DMM use the best possible range (largest detail without exceeding the display).
c. on DMM read the display value with unit given by the range (K, M...) (in DMM should NOT multiply by range factor)
d. at each change of R range, it should NOT adjust the 0 (tips shorted).
e. I should be measured in series (break the circuit).

<u>7. Measurement with Osciloscope:</u>
Connect the output of the function generator (FG) to the channels of the scope, with the FG with a sine or triangular wave, 100, 500, 1k or 5kHz, changing for each pair.
-.Read V and f (frequency).
-.Measure the sine RMS voltage DMM and compare to the scope's reading. (Vp/1.41).

a. adjust beam to horizontal central position.
b. adjust intensity a little under maximum.
c. adjust focus to maximum visibility.
d. adjust horizontal scan to have at most 2 cycles on screen.
e. adjust vertical deflection so the wave occupies 40 a 80% of the screen. (not too large nor too small)
f. adjust trigger to automatic.
g. knobs of vertical deflection, horizontal e trigger should be on calibrated position.
h. V should be measured in parallel, multiplying the divisions by the range.
i. should measure V peak and calculate Vrms=Vp / 1.41
j. measure period T (divisions x hor. sweep) and calculate frequency (f=1/T).
k. should know how to adjust the FG to sine wave and to choose output level and wanted frequency.
(CHANGE SETTINGSAT EACH NEW PAIR)

EXAMPLES OF QUESTIONS OF CIRCUITS FOR ANALISYS
<u>8. Interpret the DC circuit behavior:</u>
a. recognize the different types and values of capacitors and diodes
b. observe the division of current in parallel circuits and the division of voltage in series circuits.

<u>9. Interpret the behavior or AC circuits (requires 2 channel scope).</u>
a. observe the difference of phase between Vr and Vc to go down as the sine frequency goes up.
b. observe the Vcap in RC circuit, explaining why a square wave transforms into a triangular one by increasing the frequency (the period decreases, there's not enough time for the capacitor to totally charge and discharge it on dV/dT, but they hadn't seen that yet).

<u>TIME</u>:
a. the exam should last 20 minutes at most; up to 30 is allowed, but cuts 1 point from total;
b. If after 30 is not finished, interrupt and count only what is done, to avoid exceeding total number of days due to too many students. DON **<u>NOT</u>** EXCEED 30 MINUTES!

APPENDIX 3: EXAMPLE OF STUDENT CONTROL PER STUDENT (0.25 POINTS PER ITEM)

1							1
2							2
…							7j
7k							7k
8ª							8a
8b							8b
9a							9a
9b							9b

Working with differences: keeping motivation and generating satisfaction

Dulce Márcia Cruz[1], *Marialice de Moraes*[2]

Abstract — *A central problem for institutions that provide distance education is how to develop courses that are adequate to the existing demands, preventing the high rates of "dropout", and increasing students' satisfaction. The Distance Education Laboratory of the Federal University of Santa Catarina/ UFSC (Brazil) has been researching the possibilities to attend the specific needs of several groups of students, and at the same time paying attention to the individual expectations. In this paper we present some results of the empirical observation of graduate programs offered to working adults, registered through their companies and/or institutions, using interactive media - videoconference and Internet. Despite some common characteristics, these programs have been observed as intrinsically different, since the student enrolled came from diverse contexts and had very different demands. Observing the results obtained by the students in terms of performance and completion of the 15 graduate programs that begun in 1998/1999 we noticed that despite of the above mentioned differences among the student groups the drop out rates were below the data found in the related DE literature. In this sense we may conclude that the importance of the instructional design process, students support service (local and remote), and the professional circumstances of the students are determinant factors of success.*

Index Terms — Distance Education, drop out rates, motivation, students support service.

INTRODUÇÃO

Um problema central para as instituições que ministram cursos a distância é o de garantir que os alunos consigam terminar seus estudos de maneira satisfatória. A partir da proposta de alcançar uma grande diversidade de estudantes mas ao mesmo tempo garantindo a atenção às suas necessidades individuais é que foi desenvolvido o modelo dos cursos de Pós-Graduação Stricto Sensu em Engenharia de Produção da Universidade Federal de Santa Catarina, mediados pelo Laboratório de Ensino a Distância. Baseado na utilização consorciada da videoconferência e da Internet, o modelo permite uma ampliação das possibilidades de contatos síncronos entre alunos e professores, e entre estes e os colegas. Além das aulas por videoconferência, outras estratégias são utilizadas com o objetivo de incrementar a interação e a construção de um senso de pertencimento, de comunidade, como as aulas presenciais no início de cada disciplina, *workshops*, seminários presenciais e um ambiente de aprendizagem on-line com espaço para aprendizagem colaborativa, além da atuação do monitor.

Apesar de serem todos cursos de Mestrado a Distância, há uma grande variedade de áreas de conhecimento, com alunos vindos de diferentes contextos e demandas as mais diversas. Essa diversidade no entanto, resultou em uma taxa de *dropout* dos primeiros cursos bem abaixo do verificado na literatura da Educação a Distância. O objetivo deste artigo é o de tentar, através da descrição do modelo e das características das parcerias e de seus alunos, levantar algumas hipóteses sobre quais seriam os fatores responsáveis por esses índices de finalização e retenção dos alunos na EAD.

SISTEMA DE APOIO AO ALUNO

Uma breve revisão da literatura sobre o papel dos serviços de apoio ao aluno na Educação a Distância, nos mostra que este setor e os profissionais que nele atuam são fatores determinantes para o sucesso de qualquer iniciativa de EAD. Ref. [1] afirma que a melhoria da EAD nas últimas décadas está parcialmente relacionada com a melhoria da oferta de serviços de apoio aos estudantes. Ref. [2], vão mais longe e afirmam que apoio ao aluno é fator crítico para o sucesso dos programas de educação a distância. A importância dos serviços de tutoria, monitoria e suporte é fundamental para desenvolver a autonomia dos alunos, especialmente se considerarmos o fato de que na EAD, o aluno será sempre estimulado a demonstrar habilidade de trabalhar sozinho (ou em grupos "virtuais") e saber buscar apoio quando necessário [3].

O NOVO ALUNO A DISTÂNCIA: AUTONOMIA E MOTIVAÇÃO

Partindo-se do pressuposto de que o aluno é o centro de qualquer processo educativo de qualidade, tal deve ser o caso na EAD. O aluno a distância é figura central do

[1] FURB – Universidade Regional de Blumenau. dulce@eps.ufsc.br

[2] Laboratório de Ensino a Distância – (LED). Programa de Pós-Graduação em Engenharia de Produção – UFSC. mariali@led.ufsc.br

processo de ensino-aprendizagem e todo o curso é desenhado objetivando a otimização do seu desempenho. Uma das regras de ouro para o sucesso de um programa de EAD é o conhecimento do público-alvo para o qual se está planejando [4]; [5];[6]. Quem é este aluno? Quais as suas expectativas? O que ele busca/necessita? Responder estas questões, ainda que de forma ampla e genérica, é uma tarefa primordial para as instituições de EAD.

Diversas pesquisas mostram que para que uma abordagem educacional realmente possa ser vista como "centrada no aluno" [7]; [8]; [9], são necessários investimentos efetivos nos aspectos críticos que afetam a disposição do aluno para estudar a distância, o que pode impedir o aluno de se matricular e progredir, assim como os aspectos motivacionais, sendo que devem ser consideradas aí as questões familiares, econômicas, disponibilidade de tempo, características pessoais, etc. [10].

Os estudantes que buscam cursos à distância formam, segundo [8], "(...) uma clientela especial. Ela é diferente da do (sic) estudo com presença, porque por via de regra se trata de adultos *um pouco mais velhos*. Sua idade média situa-se entre 20 e 30 anos, sendo que para cima dificilmente se coloca um limite".

Para o aprendiz adulto, o mais importante é incorporar novos conhecimentos ao que já possuem, obter respostas para suas necessidades e não apenas em aprender por aprender. Eles estão mais inclinados a desafiar professores e colegas com experiências da vida real que contradizem estudos hipotéticos. "Estudantes adultos trazem uma grande variedade de interesses e experiências para a sala de aula; instrução que aproveita esta riqueza torna-se mais profunda e envolvente para todos" [11].

Estar motivado é um fator fundamental para que o aluno a distância realize as suas atividades e conclua satisfatoriamente seus estudos. Segundo [12], a motivação é um fator primário para o processo de aprendizagem. Para esta autora, "Sem o desejo de aprender, raramente irá acontecer uma aprendizagem efetiva" [12]

Para Ref. [13] a motivação é uma disposição autônoma, algo que é interno a pessoa. Para a autora este fato por si mesmo determina que qualquer intervenção no processo motivacional só irá até onde o alvo da ação permitir.

Ao falar sobre a importância da motivação do aluno na EAD, Visser destaca que ainda existem poucas iniciativas especificamente elaboradas com o objetivo de estimular e manter o aluno motivado para os estudos:

"A importância do desenvolvimento de estratégias para aumentar a motivação foi muito pouco estudada e não foram feitas muitas tentativas para auxiliar no design de materiais para cursos e/ou auxiliar instrutores a produzirem materiais motivadores" [13, p. 4].

Ainda segundo [13], na EAD, ao contrário do ensino-aprendizagem convencionais onde o contato presencial regular entre estudantes e professores permite que os problemas de ordem motivacional sejam rapidamente identificados, é mais complicado detectar este tipo de situação e, portanto, não há uma ajuda externa efetiva para aumentar a motivação. Ou seja, para a autora, a inclusão de estratégias motivadoras nos materiais didáticos é uma forma de estimular a motivação dos estudantes a distância para a aprendizagem.

Em pesquisa realizada com um grupo de estudantes em um curso a distância oferecido pela OU, a autora identificou uma série de fatores positivos relacionados com a utilização de mensagens de caráter motivacional e o desempenho e a persistência dos alunos no curso. Abordagem adotada foi o envio de mensagens motivadoras aos estudantes de um curso baseado em correspondência durante oito meses, oito vezes; resultaram em um aumento das taxas de finalização de 35% para 71% e de 35% para 84% no caso dos alunos que se matriculavam pela primeira vez. Os resultados também foram efetivos no sentido de que houve um aumento da autoconfidência (self-confidence), como um aprendizado para toda aa vida [14].

Ref. [15] aponta para a necessidade de se desenvolver uma estratégia para a retenção de alunos na Open University - OU, uma vez que o problema de evasão é um dos mais importantes para a universidade, como indicam alguns números: 5% dos alunos abandonam cursos no início ou no primeiro terço; 30% dos que iniciam seus cursos, não chegam a fase de exames; apenas 65% dos que chegam a fase de exames, passam. Por essa razão a OU está implementando um projeto denominado "Student Retention Program", voltado justamente para a retenção dos alunos e baseado no apoio ao aluno e na manutenção da motivação para os estudos [15].

Ref. [16], também destaca em seu trabalho a importância da motivação para o desempenho e persistência dos alunos em cursos a distância. A realização de atividades busque estimular o aluno para manter-se motivado e persistir até a conclusão efetiva de seu cursos é vista como uma atividade central no modelo de apoio ao aluno a distância implementado no LED.

ÍNDICES DE DESISTÊNCIA E EVASÃO NA EAD – DROPOUT RATES

Índices de desistência e evasão (*dropout rates)* mais altos que na educação tradicional são, infelizmente, uma característica que ainda marca a EAD, como é possível identificar nas citações a seguir:

> *"Ainda que as pesquisas mostrem que os estudantes a distância aprendem tanto quanto estudantes convencionais, estudos realizados com estudantes em cursos por correspondência*

> *identificaram que estes tendem muito mais ao abandono de seus cursos, com as taxas de evasão e desistência variando de 19% a 90%, com uma taxa média de 40%" [17].*

> *"Mesmo que as estatísticas variem em diferentes instituições, administradoras escolares concordam que as taxas de conclusão de cursos a distância são geralmente 10 ou 20% mais baixas que em cursos tradicionais" [18].*

Em relação aos números de dropout apontados na literatura e os números percebidos no contexto do LED, é importante destacar uma diferença básica: a característica da oferta (aberta/fechada) e dos cursos (extensão, graduação, pós-graduação). No caso do LED, os cursos analisados são de pós-graduação e oferecidos, em sua maioria, para um único parceiro, que conhece os alunos, que formam grupos mais ou menos homogêneos. Nos casos descritos na literatura os cursos são em sua maioria oferecidos de forma aberta, para alunos de origens diversas.

Ainda, segundo [19], é preciso também que, ao se fazer comparações entre dados oriundos de cursos tradicionais e cursos a distância se leve em consideração as características de ambos os grupos de estudantes, especialmente quando se analisam cursos regulares. Para o autor, os alunos a distância fazem parte de um grupo onde os fatores externos (trabalho, família, finanças) têm muito mais chances de levar ao abandono do curso.

As discussões sobre índices de evasão e desistência são freqüentes na EAD, muitas vezes levantadas por profissionais que não acreditam na eficácia desta modalidade de educação. Mas, uma análise mais detalhada das pesquisas indica que, se a estrutura de apoio oferecida pela instituição de EAD for eficiente, os índices de evasão e desistência tendem a ser menores [15].

LED – LABORATÓRIO DE ENSINO A DISTÂNCIA

O Laboratório de Ensino a Distancia (LED) foi criado em 1995 no Programa de Pós-graduação em Engenharia de Produção (PPGEP), da Universidade Federal de Santa Catarina (UFSC), para estabelecer uma ligação efetiva entre a indústria e a academia, visando atender a uma crescente demanda por estudantes vindos das empresas. O objetivo de garantir uma relação com o setor produtivo presente no processo de implementação do LED incluía inclusive em seu projeto inicial, a criação de salas de videoconferência dentro dos empresas parceiras.

A videoconferência foi escolhida como mídia principal dos cursos de pós-graduação tendo como mídias de apoio a internet e o material impresso. Os cursos por videoconferência do Programa de Pós-Graduação em Engenharia de Produção (PPGEP) da UFSC começaram a ser oferecidos para as empresas e instituições educacionais com base na estrutura da pós-graduação das universidades brasileiras.

Em 1996, foi realizado o primeiro curso de especialização para engenheiros da Equitel, uma empresa da área de telefonia integrante da Siemmens do Brasil, em Curitiba, em que a base para a transmissão dos conteúdos era a videoconferência e o envio de material didático era feito através dos correios.

O segundo curso nasce em 1997, com o parceiro A, uma empresa líder mundial na produção de petróleo em águas profundas, oficialmente o primeiro realizado a distância pelo PPGEP. Por necessitar treinar engenheiros localizados em sete cidades brasileiras, decidiu-se pelo multiponto e, por possuir uma intranet ativa, o curso foi planejado para incluir as ferramentas da Internet, além de material impresso e aulas pela videoconferência.

FORMATO DOS CURSOS

O Mestrado por videoconferência do Programa de Pós-Graduação em Engenharia de Produção (PPGEP) da UFSC para o parceiro A acabou sendo o marco para todos os outros cursos que se seguiram. Na adaptação para educação a distancia, seguiu o modelo presencial de tempo, conteúdo e carga horária de aulas. Seu formato básico era composto por aulas por videoconferência e comunicação extraclasse principalmente pela Internet, três ou quatro trimestres de duas disciplinas, ministradas em dois períodos por semana, de quatro horas-aula de 50 minutos cada, com pelo menos um encontro presencial entre alunos e professores durante a época dos créditos, foi seguido com poucas variações na maioria dos cursos atualmente em vigor.

Apos o período das aulas, os alunos entravam em fase de orientação visando a execução do projeto de pesquisa e a redação de uma dissertação de Mestrado a ser defendida de forma oral para uma banca de no mínimo três doutores. A finalização desse processo segundo a legislação brasileira da pós-graduação deve levar 24 meses. Os alunos que não conseguirem terminar a dissertação nesse prazo podem pedir mais um ano e, na eventualidade desse ano não ser suficiente, a coordenação do Programa pode conceder mais um, somando um total de quatro anos ao final. Como indicação da pressão exercida sobre professores, alunos e cursos, e preciso dizer que conta ponto na estrutura educacional da pós-graduação brasileira a finalização das pesquisas e a defesa das dissertações no prazo mínimo de dois anos. O adiamento ou a demora na defesa pode acarretar entre outros prejuízos o rebaixamento no ranking nacional de cursos e a conseqüente perda de bolsas de estudos para os alunos e financiamento de projetos do governo federal para os professores.

A ORIENTAÇÃO DAS DISSERTAÇÕES

Encerrada a etapa de cumprimento dos créditos, começavam os seminários de orientação para a realização da pesquisa e da dissertação. Pelo modelo do PPGEP usado com o parceiro A, uma vez concluídos os créditos, tinham início os seminários trimestrais de orientação a distância, realizados em sessões multiponto por videoconferência. O objetivo dos seminários era o de servir como mecanismo de sistematização da pesquisa, que auxiliasse os alunos a socializar suas experiências, trocar bibliografia e discutir seus trabalhos com os colegas recebendo orientação não só dos seus mas também dos outros professores-orientadores, presentes à sessão. Planejados como um encontro de todos os alunos, os seminários visavam criar um espaço necessário para impedir que após o período de créditos, eles se dispersassem ao iniciar seus trabalhos individuais de pesquisa, buscando manter a coesão e o sentimento de pertencimento à instituição educacional.

A partir de 1999, quando os outros cursos por videoconferência do PPGEP entraram em fase de dissertação, o modelo foi modificado para seminários presenciais, já que estes eram essencialmente realizados ponto a ponto, ou seja, ligando apenas uma sala da instituição parceira ao LED. Por essa razão, ao invés de reunir-se com todos os professores orientadores, os alunos passaram a se encontrar apenas com o coordenador acadêmico dos cursos, que viajava até a cidade da instituição para realizar o encontro, mais para um atendimento socializante, de motivação e esclarecimentos metodológicos do que de discussão dos conteúdos, como era o caso da Petrobras. Com isso, a orientação de conteúdo específico para cada dissertação passou a ser canalizada para acontecer apenas através da relação individual entre orientador e orientando, ocorrendo na maior parte do tempo, à distância. Isso porque, numa grande parte dos casos, o primeiro contato presencial do orientador com seus orientandos passou a acontecer quando da visita oficial que os alunos faziam à UFSC, no final do segundo ou do terceiro trimestre letivo. Essa comunicação continuava a distância, com o uso do e-mail ou do espaço de orientação criado no ambiente Web do LED.

No início de 2000, foi criada uma coordenação de orientação, responsável por apoiar os coordenadores acadêmicos na intermediação da relação entre orientadores e alunos. A partir dessa nova estratégia, os seminários de pesquisa continuaram presenciais no local do curso e passaram a ser dirigidos pelo coordenador acadêmico e pelo coordenador de orientação, no atendimento aos alunos principalmente quanto a questões relacionadas às dificuldades pontuais, metodológicas ou de comunicação com os orientadores. Segundo essa dinâmica, os professores começaram a ser informados sobre o resultado desses seminários presenciais com seus orientandos em reuniões posteriores ao encontro, de modo a que pudessem corrigir eventuais problemas ou falhas de comunicação durante o processo de trabalho. O encontro presencial entre os coordenadores e os alunos vem seguindo o cronograma de seminários trimestrais de pesquisa, previstos a partir do final dos créditos e que prevê as etapas de desenvolvimento da dissertação que vão culminar na defesa.

Em meados de 2000, teve início a orientação através de encontros individuais por videoconferência que foi uma reivindicação dos professores no sentido de facilitar o contato e o trabalho com os alunos distantes.

A MONITORIA

A oferta de cursos de pós-graduação a distância, especialmente cursos de mestrado via VC e com o suporte da Internet para comunicação extraclasse, marcou o início do estabelecimento da estrutura de apoio aos alunos e professores no contexto do LED, em julho de 1997[3]. A responsabilidade da equipe de apoio que trabalha nos cursos de Mestrado Presencial Virtual é fazer o atendimento aos alunos sem envolver-se com as questões de conteúdo e avaliação de aprendizagem, pois estas questões dizem respeito ao professor responsável da disciplina.

Para [20] o monitor é o agente responsável pela integração deste modelo, realizando ações de socialização por meio do estabelecimento de contato entre alunos e professores e estimulando a motivação para a aprendizagem. É atribuída ao monitor também a função de auxiliar em questões de acesso tecnológico, incentivando o uso do ambiente on-line de aprendizagem e esclarecendo dúvidas referentes ao mesmo pois, a crescente utilização de tecnologias de última geração criam a necessidade de profissionais capacitados para o preparo de alunos e professores para o seu uso no contexto educacional.

Os profissionais selecionados pelo LED para a função de monitor são selecionados a partir de alguns critérios previamente estabelecidos: serem alunos de mestrado (da área de Mídia e Conhecimento, ou áreas afins), possuírem conhecimentos básicos de informática e principalmente conhecimentos e interesse de pesquisa na área de EAD. A equipe também tem características multidisciplinares contando com profissionais de áreas como sociologia, pedagogia, assistência social, ciências da computação e psicologia [21].

Como resultado de avaliação diagnóstica realizada com 471 (quatrocentos e setenta e um) de seus alunos, professores e instituições parceiras, ficou evidente uma visão bastante positiva das percepções dos alunos sobre o papel da monitoria durante a realização de seu curso, enfatizando a importância da participação do monitor em momentos cruciais. Nesta avaliação, 94% dos alunos participantes consideraram muito importante a participação dos monitores nas etapas presenciais do curso; 90% destacaram a orientação da monitoria para o desenvolvimento de atividades a distância (dicas de como estudar a distância, apoio comunicacional, etc.) e 87% deram ênfase ao contato periódico com os monitores pela Videoconferência [22].

CARACTERÍSTICAS DOS CURSOS, DOS ALUNOS E DAS INSTITUIÇÕES PARCEIRAS

O estabelecimento de parcerias para a oferta dos cursos a distância foi desde o início do processo percebido como fundamental pelo LED, que buscava formar uma rede nacional para o atendimento das demandas por cursos que chegavam ao PPGEP. Mas, o atendimento à demanda era sempre analisado sob o ponto de vista do aluno – qual o tipo de estrutura necessária nos ponto remoto, quais os serviços que deveriam ser oferecidos, etc., para facilitar a vida do aluno e permitir que este se dedicasse ao máximo aos estudos, sem preocupar-se com questões técnicas e administrativas. Neste sentido, aos contratos formais para o estabelecimento de convênios e parcerias sempre realizados pelas fundações da universidade, acrescentou-se um protocolo de responsabilidades, no qual ficava estabelecida a responsabilidade de cada parceiro em relação aos alunos, assim como as responsabilidades do LED.

Este protocolo foi identificado como necessário a partir da identificação de algumas questões problemáticas desde o estabelecimento da primeira parceria para oferta de cursos a distância via videoconferência e foi sendo aperfeiçoado conforme os cursos iam acontecendo. O protocolo determinava que a instituição parceira deveria contar com uma estrutura mínima para o atendimento local aos alunos, com especificações relacionadas às questões técnicas, de pessoal, estrutura física (sala de aula, sala de estudos, biblioteca).

A necessidade de uma estrutura local de apoio, com monitores e técnicos capacitados, foi em muitos momentos apontada pelos alunos em suas avaliações, elogiando ou criticando a estrutura local. Em alguns momentos foi necessário parar os cursos para realizar ajustes nesta estrutura, a pedido dos alunos.

Cursos do parceiro A

Os cursos desta parceria diferenciam-se dos demais especialmente pelo fato de serem oferecidos para uma empresa, o que gera uma grande homogeneidade no perfil das turmas, composta em sua maioria por engenheiros, mesmo que de áreas distintas (Química, Mecânica, Naval), com uma concentração muito grande de alunos na faixa etária entre 35 e 49 anos. A área de concentração – Logística – e o fato de ser baseado na utilização da videoconferência multiponto apresentaram uma preocupação inicial, mas a adaptação do grupo foi rápida e os professores também se apropriaram com alguma facilidade da tecnologia. Em relação ao uso da Internet, este apresentou problemas e a difusão foi bastante lenta, especialmente por causa da falta de familiaridade dos professores e sua hesitação em utilizar também esta tecnologia.

Todos os cursos oferecidos no âmbito desta parceria tinham as mesmas características, sempre na mesma área de concentração e com o mesmo corpo docente. Também os alunos tinham características comuns em todos os grupos, o que variava era apenas dispersão geográfica dos grupos, conseqüentemente, a diversidade cultural de suas origens.

A instituição parceira já possuía anteriormente uma estrutura bastante favorável para o estudo in-company, facilitando algumas adaptações solicitadas pelos professores e alunos. A familiaridade dos alunos com o uso da Intranet da empresa também facilitou a comunicação extraclasse, via e-mail, e a troca de materiais, amenizando os problemas ocorridos com a conexão com a Universidade. A existência de uma biblioteca própria também se apresentou como um fator muito positivo, especialmente na fase de dissertação.

Cursos do parceiro B

A parceria aqui denominada como "parceria B" era formada por um grupo de instituições de ensino superior distribuídas pelo estado de SC, caracterizando-se como um consórcio de IES. Todos os alunos eram professores vinculados as instituições-membros do consórcio e estavam realizando o curso por que necessitavam da titulação para continuarem lecionando em suas instituições, devido às mudanças na legislação trazidas pela nova LDB, homologada em dezembro de 1996. Estes fatores tornavam a realização do curso como obrigatória, em muitos momentos refletindo-se na motivação dos alunos, que viam o curso com "mais uma" tarefa em uma vida já bastante atribulada pelo trabalho como docente, muitas vezes em diversas instituições.

Uma questão importante a ser considerada aqui é a falta de experiência com a tecnologia utilizada – videoconferência – nos pontos remotos (as IES localizadas no interior do estado de SC), pois apesar de terem recebido os equipamentos e terem o acesso ao link dedicado, estas não tinham ainda resolvido questões políticas internas relacionadas ao uso desta mídia.

Em relação a estrutura local oferecida aos alunos, também houve pouco empenho das instituições, pois afinal os alunos trabalhavam naquele local, conheciam os técnicos, enfim, "podiam se virar". Assim sendo, apesar de todas as salas terem recebido equipamentos semelhantes para a realização da aula por videoconferência, não foi montada uma infra-estrutura especial para estudo, biblioteca específica, etc.

Um ponto importante se compararmos os parceiros A e B, é a questão da diversidade de cursos oferecidos. No primeiro caso, somente em uma área, no segundo caso em 5 área diferentes dentro do âmbito do PPGEP. Mesmo para a equipe de apoio no LED estes cursos representavam um desafio, pois envolviam um corpo docente bastante numeroso, e áreas bem distintas (Qualidade, Engenharia de Avaliação, IA).

Cursos do parceiro C

Os cursos oferecidos por este parceiro foram os primeiros a serem oferecidos de forma aberta, pois apesar de existir uma instituição mediadora (a parceira), os cursos eram oferecidos para qualquer interessado que obedecesse aos requisitos formais de admissão do Programa. Esta abertura e a oferta de cursos de áreas de concentração diferentes fez com que o público-alvo atendido se tornasse bastante diversificado, dificultando também a formação de grupos coesos, como aqueles onde todos os alunos estava vinculados às mesmas instituições. Estas turmas eram compostas por professores, administrados de instituições de ensino, profissionais liberais, e outras categorias, sendo um fator de possível identificação entre estes alunos o fato de que a maioria exercia ou pretendia exercer alguma atividade docente.

Desde o início dos cursos, ficou patente no contato da equipe do apoio no LED com os alunos que o parceiro não oferecia a infra-estrutura física e de pessoal estabelecida no protocolo encaminhado pelo LED. Os alunos sentiam-se abandonados e não sabiam com certeza a quem recorrer. Não havia sala de estudos, a biblioteca e a secretaria não funcionavam no horário das aulas, os técnicos eram inexperientes. Estas questões foram sendo solucionadas com a ajuda da equipe de apoio no LED, fazendo com que os alunos se sentissem mais seguros.

Estas diferenças entre os parceiros e nas características dos alunos foram claramente percebidas pelos professores que trabalharam nos cursos das 3 (três) parcerias aqui citadas, como é possível perceber nos depoimentos apresentados a seguir.

OS ALUNOS A DISTÂNCIA SOB O PONTO DE VISTA DOS PROFESSORES

Numa pesquisa realizada no LED com os professores que ensinavam nos cursos a distancia entre 1997 e 2001, [23] levantou depoimentos que mostravam que havia entre os docentes uma percepção de que a origem dos alunos era importante para um rendimento escolar positivo ou não.

Em seu levantamento, [23] demonstra que o fato do aluno a distância ser um adulto que não se afastava da rotina pessoal e profissional para estudar, era visto como um problema para os professores, justamente por que dedicavam menos tempo aos estudos.

A dificuldade de acesso à bibliografia e a questão da idade era entendida como um problema para alguns professores, mas não havia consenso sobre isso. Para um professor, por exemplo, a experiência compensava as limitações de tempo e disponibilidade de dedicação. Já um outro declarou que o tempo de vida impedia um rendimento melhor nas aulas, e que ele tinha mais paciência e preferência em lidar com os alunos jovens pois eles tem mais pique e são mais abertos à descoberta.

Além dessas diferenças apontadas na bibliografia de EAD, [23] mostrou ainda que, no caso dos cursos do LED, os professores identificavam dois grupos de alunos a distância: os vinculados às empresas (engenheiros) e os vinculados às instituições educacionais (docentes). Essa diferenciação se fez sentir especialmente nos depoimentos coletados em 1998, quando os docentes eram em sua grande maioria, oriundos dos cursos de Engenharia de Produção ministrando aulas diretamente para os engenheiros das empresas (como os do parceiro A) e, ao mesmo tempo, para professores das universidades do interior de Santa Catarina (os do parceiro B).

A diferença de origem, formação e motivação para estudar eram sentidos de modo bastante evidente pelos professores do PPGEP:

> *"Eles [os professores] estão ali porque precisam de um título, e na empresa, eles estão ali porque precisam mostrar o que eles fazem. Eles estão sendo julgados, inclusive. Porque o que eles estão fazendo tem que mostrar aplicabilidade. E já é uma coisa da empresa, quer dizer, já é um privilégio a empresa estar bancando..." [23]*

Talvez por essa razão, os docentes-alunos eram considerados mais difíceis de motivar e de participar na aula. Para os professores que ensinavam nos dois tipos de cursos, os alunos "práticos" (engenheiros) eram mais exigentes em termos de aplicação da teoria e os "acadêmicos" (professores) eram mais voltados à discussão teórica. Assim, a homogeneidade de conhecimento anterior da turma, a motivação pessoal, experiência profissional, heterogeneidade ou homogeneidade de informação anterior na área do curso foram apontados como fatores definidores das diferenças entre os dois grupos.

Pelo descrito, pela avaliação dos professores sobre seus alunos a distancia, jogavam papel fundamental na performance tanto a área profissional, a cultura organizacional de origem, as pressões exercidas pelos seus locais de trabalho, como também a estrutura de apoio recebida tanto na instituição presencial quanto na da universidade a distância.

PERFORMANCE E FINALIZAÇÃO DAS DISSERTAÇÕES DOS CURSOS DE MESTRADO A DISTÂNCIA

Do que foi discutido até agora, percebe-se que há uma grande diversidade tanto entre as condições dos parceiros, como entre as áreas e disciplinas dos cursos ministrados como entre os grupos de alunos das diversas turmas. Uma questão interessante a se fazer em uma realidade como essa seria a de investigar se os alunos de cursos de formação homogêneos mais coesos (tais como os da empresa A) teriam mais condições terminar seus projetos ou se o fato da proximidade de interesses profissionais (qualificação para docência no caso dos parceiros B e C) mesmo que heterogêneos em suas origens funcionariam como um fator de motivação para reter o aluno até o final?

Na tentativa de verificar essas questões, foram levantados dados referentes aos prazos de conclusão dos alunos das parcerias A, B e C que iniciaram em 1997 e concluíram em dezembro de 2001 seus Mestrados em Engenharia de Produção na UFSC.

Em primeiro lugar, verificou-se que a taxa de desistência desses cursos durante o período de créditos foi bastante baixa, ficando a grande maioria de não concluintes entre os que não defenderam as dissertações. Por exemplo, no caso do parceiro A, 31% desistiram na primeira turma enquanto que a desistência no curso 2 não houve desistência. A desistência nos cursos do parceiro B variou de 13% em um dos cursos, chegando a 50% em outro, enquanto que nos restantes a media ficou em torno de 31%.

Uma primeira hipótese a que se pode chegar é talvez o fato de que estar em grupo nas aulas por videoconferência pode ter dado aos alunos um sentimento de pertinência com influência sobre a motivação para continuar. Pode ter contado positivamente para essa permanência, a satisfação com o curso, com os professores e o atendimento pela monitoria, cujos índices foram bastante satisfatórios, conforme se pode verificar nas avaliações diagnósticas realizadas no decorrer das aulas.

Para se ter uma idéia da taxa de retenção dos Mestrados por videoconferência em Engenharia de Produção pode-se verificar o número de defesas de cada parceiro.

Uma primeira análise dos resultados dos alunos que concluíram seus mestrados por videoconferência e internet mostra que, dos 15 cursos, apenas três tiveram uma porcentagem de menos de 44% de defesas e dois tiveram 77% e 91% de finalização. O restante, 10 cursos, teve uma média de 50 a 64% de alunos concluintes. Essa taxa de retenção está bem acima da relatada na bibliografia de EaD.

Vistos em conjunto, pode-se dizer que, apesar das diferenças, a porcentagem de finalização não se mostra especialmente diferente apesar da diversidade dos cursos. Uma hipótese seria a de que joga na capacidade de terminar um curso a distância a motivação intrínseca do aluno, ou seja, aquele automotivado que consegue terminar o que se propõe apesar das dificuldades.

No entanto, se for considerado o prazo regulamentar de término do Mestrado, que é de dois anos, a porcentagem de defesas diminui bastante. É o caso do parceiro A, cujos cursos tiveram três defesas no prazo no curso 1 e quatro no curso 2, o que representa um baixo índice de defesas no computo total. Por outro lado, a média de defesa dentro do prazo dos cinco cursos do parceiro B foi de 19%, sendo que dois cursos não tiveram nenhuma dissertação defendida no prazo. Do mesmo modo, dos sete cursos do parceiro C, apenas dois tiveram uma dissertação defendida no prazo e dos restantes, 100% das defesas ocorreram depois dos dois anos. (FERRARI, 2002)

Pode-se dizer que joga papel fundamental nessa tendência de finalização perto do limite dos prazos legais, alguns aspectos já apontados neste artigo, a saber: a) pressão tanto da instituição a distância quanto do parceiro local para que os alunos completassem as defesas no prazo final; b) criação da Coordenação de Orientação em 2000, que coincide com um acentuado aumento das defesas; c) pressão das empresas no sentido de cobrarem de seus funcionários a realização do Mestrado como retorno ao investimento em sua formação; e finalmente, e) como um fator de conjuntura a fortalecer a motivação de todos os envolvidos na finalização dos cursos, poderia se acrescentar a importância das defesas para legitimidade da própria EAD, já que, no caso brasileiro, a pós-graduação a distância ainda não está regulamentada. Uma hipótese para a quantidade de defesas fora do prazo seria a de que elas foram resultado de um esforço das instituições e empresas envolvidas que levou professores, monitores e coordenadores locais e remotos a buscarem nos alunos as condições e a vontade necessárias para finalizar e defender suas pesquisas.

A ocorrência de tempos diferentes de defesa pode apontar para fatores relativos à situação laboral dos alunos. Por exemplo, no caso do parceiro A, relatos dos alunos colhidos tanto durante a fase de créditos quanto na de pesquisa, revelaram que por necessidades profissionais do seu local de trabalho, os estudantes eram chamados a exercer suas funções cotidianas ou mesmo a aplicar suas pesquisas antes mesmo de conseguirem defender as dissertações. Muitos tiveram que desistir por causa da carga intensa de trabalho.

CONSIDERAÇÕES FINAIS

Apesar da dificuldade de se isolar os diferentes fatores intervenientes nos cursos acima analisados, pode-se levantar alguns aspectos que merecem atenção. O primeiro deles é que o desenho instrucional dos cursos do PPGEP, baseado numa alta interatividade com agentes motivadores como os monitores e orientadores pode ser um dos fatores de finalização dos mestrados a distância. A infraestrutura de apoio ao aluno, tanto local como remota, que foi desenvolvida conforme o modelo foi sendo criado, mostrou-se importante especialmente na fase final do limite do tempo para as defesas. E finalmente, o fator profissional, tanto na pressão para voltar a exercer suas funções no local de trabalho, quanto na motivação para alcançar o certificado necessário para continuar trabalhando, pode ter pesado na porcentagem de *dropouts* e finalizações.

Por esses aspectos apontados, percebe-se que ainda há muito que pesquisar nessa área de apoio ao aluno, para se conseguir identificar não só quais são as principais variáveis que interferem na motivação dos alunos mas também até que ponto e de que maneira elas exercem seu papel nesse processo tão complexo.

TECHNICAL WRITING FOR CONSTRUCTION SCIENCE GRADUATES

Ifte Choudhury[1], Ricardo E. Rocha[2] and Richard Burt[3]

Abstract *—The purpose of this study was to determine the perceptions of the construction industry as well as the construction educators regarding the need for technical writing skills among Construction Science graduates. An instrument was prepared to gather the data related to the technical writing skill set of construction science graduates. This instrument was sent to the CEO's of the construction companies, identified from Texas A&M University's Department of Construction Science Career Fair Database, and faculty members of in the Associated Schools of Construction. The results of the survey were used to determine the importance of different construction documents used within the construction industry for which good technical writing skills are essential. The data was analyzed using stepwise and multiple regression techniques. The results from the study indicate that capability of writing business letters, request for bid information, e-mails, and miscellaneous items such as schedule of values and submittals are important in terms of technical writing. All these factors were found to be related to the overall capability of technical writing skills among Construction Science graduates at a level of significance of 0.05.*

Index terms — Construction Science, Construction Documents, Technical Writing.

STATEMENT OF THE PROBLEM

A person's ability to communicate effectively through the use of technical, written, communication skills can greatly affect their career. An individual's capacity to write effectively is usually regarded as a first-rate attribute. It can be categorized equally with a person's professional skills and knowledge. Professionals in all disciplines, including construction, spend a considerable amount of their time in writing technical reports. It is a critical component to all tasks of significant importance.

Given this importance, industries report that students graduating from technical programs are generally not well prepared for the writing requirements of the contemporary workplace [1]. Industries naturally have their own set of terminology committed to the specific requirements and situations exclusive to their form of business. Communicating effectively within an industry is a direct result of an individual's ability to understand and use the industry's vocabulary and communication practices. Effective written communication skills can assist in the [1]acquisition of sought-after contracts and clients as well as assist in maintaining optimal relationships with vital customers.

Project documentation is critical to the success of many companies. Understanding and learning how to prepare a variety of construction documents is of the utmost importance to construction professionals. The purpose of this study was to identify the importance of different construction documents used within the construction industry. This information in turn will be used as the structural framework in establishing a construction oriented technical writing class at Texas A&M. University.

REVIEW OF LITERATURE

Overview

With the growth of the U.S. college student population in the 1960's and early 1970's universities and community colleges recognized that a high percentage of students had problems writing effectively [2]. Leaders in industry have stated that for nearly 50 years, the continuing weakness of graduating technical students has been their lack of written communication skills [1].

The inability to communicate effectively does little to enhance the image of a company. In fact, it proves to be detrimental. Good writing skills are necessary in order to communicate with clients, as well as with partners and co-workers. How successfully a company communicates potential problems and issues will largely depend on the writing and communication skills of the company employees [3]. In the construction profession, reading and writing are paramount to an individual's performance in successfully completing a project [4].

Every industry has an undefined list of terms that are essential to the specific requirements and situations unique to that industry. An individual can successfully communicate within an industry when they have mastered the terminology and methods of communication relevant to that industry. When students graduate from their

[2] Ricardo E. Rocha, Department of Construction Science, Texas A&M University, College Station, TX 77843
[3] Richard Burt, Department of Construction Science, Texas A&M University, College Station, TX 77843

respective programs, they will be given a wide range of activities and projects that will require them to exhibit acceptable documentation and writing skills [2]. There are few commercial endeavors that use and rely on written language skills as much as construction contracting does [5].

Being unable to acceptably execute these basic skills, new graduates will find themselves at a considerable disadvantage [5]. Many construction programs offer courses in subject areas ranging from building materials and methods to structures and environmental systems. It would be logical to believe that these are the skills essential to one's success in the construction industry [5]. In reality, the most important skill to be taught is the ability to write effectively [5].

It is no secret that construction education graduates are deficient in possessing adequate writing skills for entering the business community [6]. Understanding that these skills need to be improved is the first step in correcting the problem [4].

Teaching Relevant Material

In order to fill the void in writing skills educators must focus their attention on writing as a fundamental communication skill [6]. It is important not only to make students write, but to have them write on subject areas relevant to their studies [4]. It appears to be nonproductive to teach writing without concurrently teaching the subject matter [6]. According to Wright [6], if educators expect writing skills to be developed only in English specific-type courses, it is imperative that such courses be provided relevant content and set the context in the students' limited experience in language usage [6].

Employers demand that entry-level employees effectively write as it relates to specific conditions of a particular project [4]. Professionals spend approximately 20 percent of their time writing reports of some sort. Graduates must know how to write competently and exhibit this competency immediately on entering the industry in order to be successful [5].

If the problem has been readily identified it would be the assumption of many that colleges and universities would make the development of first-rate writing skills an important goal and assign some of their best instructors to the accomplish the task. Unfortunately, this is typically not the case [1].

Many professors in English departments usually specialize in a particular form of literature and not in English composition. Many will privately admit that they do not nor want to know how to teach composition writing courses. Many of these professors are poorly prepared to evaluate the obscure information usually entailed in technical topics. Since the information cannot be judged on content, most instructors will invariably revert to issues of format and technique. In short, the writing in many areas of composition and technical writing courses does not reflect the kinds of writing that the modern workplace expects students to do [1].

Writing-Across-the-Curriculum

Regardless of the style and amount of writing in specific English courses, the evidence was apparent. A "gap" appeared between the writing competency displayed in a composition course and the writing performance in the type used by the individual students' professional disciplines [2]. The response to this performance gap has led to what is now termed writing in the discipline (WID) [2].

This method of writing allows students to become accustomed to the style of writing associated with their disciplines and immerses them in the professional dialogue of their field [2].

Writing across the curriculum at its onset uses the approach that every teacher, instructor or professor should become aware and should introduce into his respective classroom and curriculum, the requirement of student participation by writing [2].

Writing across the curriculum is a theory of writing rested on the basis of deeming writing as a revised process, not a consecutively manufactured product. Other theoretical components of writing across the curriculum can be summarized as follows:

- An interdisciplinary dialogue on writing that brings writing into as many classrooms as possible.
- Brief and varied (cross-disciplinary) writing forms that receive both instructor and peer responses.
- A focus on writing as learning – the principle that cognitive processes involved in writing and knowledge acquisition are very similar [2].

Without a requirement to master writing skills, the graduate is initially handicapped in his/her chosen professional world. This handicap continues until these skills are acquired [6]. This is despite dramatic increases in mandatory reading, writing, and speech courses; writing-across-the-curriculum initiatives; and the heavy emphasis placed on writing skills by business and industry. It is unknown as to why this crucial skill has been and is still being so inadequately addressed. This is considered by some to be the greatest failure of the higher educational system [1].

Need and Promotion

By not teaching our students to read critically and to write logically and clearly, we unsuspectingly limit their personal and professional horizons [1]. An employee's ability to advance in an organization may be dependent on that person's ability to communicate both verbally and with the written word [5]. Most all help wanted advertisement for technical people specifically requires well-developed written communication skills [1]. It is important to note that the ability to write effectively assumes a much larger role as one advances in a technical career. This causes the problem to grow to unsuspected heights.

Without adequate written communication skills, an employee may be passed over for promotion [3]. Almost every technical person can recall cases of ambitious and technically adept colleagues passed over for promotion because they could not write well enough to meet the demands of a higher position [1].

METHODOLOGY

Data Collection Procedure

A total number of 400 Chief Executive Officers were randomly selected from Texas A&M University's Department of Construction Science Career Fair database. Another 400 of faculty members teaching at different schools of construction were randomly selected from the web site of Associated Schools of Construction. A survey instrument was prepared to collect the data. It was administered via email in hopes for a speedy response, but individuals had the opportunity to mail in their responses as well. Some chose this option. Respondents were given two weeks to respond. A few days prior to the deadline, an email reminder was sent. Due to a poor response rate relative to the population, an extension of a week was given to those who had not yet had the opportunity to respond. The number of responses was 81 — 57 from the industry and 24 from the faculty. The rate of response was only 20.25 percent.

Variables and their Operationalization

Overall Technical Writing Skills (TECWRITE)

It is the reported importance of overall technical writing skills for construction science graduates.

Business Letters (LETTER)

It is the reported importance of skill for writing business letters by construction science graduates.

Schedule of Values (VALUE)

It is the reported importance of skill for writing schedule of values by construction science graduates.

Request for Information (RFI)

It is the reported importance of skill for writing request for information by construction science graduates.

E-mail (EMAIL)

It is the reported importance of skill for writing e-mail by construction science graduates.

Notices (NOTICE)

It is the reported importance of skill for notices of safety, compliance, etc. by construction science graduates.

All the variables were measured using a 5-point unidimensional scale, ranging from "strongly disagree" to "strongly agree." A value of 1 was assigned if the respondents "strongly disagreed" with a particular statement, elevating to a value of 5 if the respondents "strongly agreed" with the statement.

RESULTS

A multiple regression analysis was performed in order to ascertain the relationship between overall technical writing skills of construction science graduates and the importance of their ability to write business letters, schedule of values, request for information, e-mails, and notices. Regression analysis is a modeling technique for identifying a function that describes the relationship between a dependent and one or more independent variables. The following model was used for the analysis;

$$TECWRITE = \beta_0 + \beta_1 LETTER + \beta_2 RFI + \beta_3 EMAIL + \beta_4 NOTICE + \beta_5 VALUE + e \quad (1)$$

Where
β_0 = Intercept
β_1, β_2, etc. = Regression coefficients, and
e = error term.

The results of the analysis are shown in Table 1.

TABLE 1
Multiple Regression Analysis of Overall Technical Writing Skills

Variable	Regression Coefficient	$\|T\|$	$p<\|T\|$
LETTER	0.31447	3.30	0.0015
RFI	0.27084	2.46	0.0160
EMAIL	0.29769	2.26	0.0267
VALUE	0.19502	2.20	0.0311
NOTICE	0.19178	1.67	0.0993
Intercept = 0.64141		Model $R^2 = 0.59$	
Model $F = 21.32$		Adjusted $R^2 = 0.56$	
$p<F$ <0.0001		$DF = 5, 80$	

The F-value of the model used for the multiple regression analysis was found to be statistically significant at a level much lower than 0.05. This statistic basically tests how well the model, as a whole, accounts for the dependent variable's behavior. The predictive efficacy of the model was found to be moderately high with an R^2 of 0.59 and an adjusted R^2 of 0.56. R^2 is the coefficient of determination of the model. The larger the value of R^2, the better the fit of the model, and higher is its predictive efficacy.

The results indicated that writing skills for business letters, request for information, e-mails, and schedules of values were perceived to be important for construction science graduates. These independent variables were related to overall technical writing skill at the level of significance lower than 0.05. Only variable found not related to overall technical writing skill at this level of significance was writing of notices.

CONCLUSION

Effective skills are important for any professional. An industry depends on the ability of the skillful use of its communication practices by individuals employed by it. The study reveals that writing of construction related business letters, request for information, skillful use of electronic communications, and preparation of schedules of values are important for construction science graduates. Both the construction industry and faculty perceive that in order to achieve technical writing skills with reference to the industry, the construction science graduates should focus on achieving excellence in these industry-specific areas.

It may be worthwhile to include the topics that have been found to be important in the curriculum for technical writing for Construction Science students. A longitudinal study may be done to assess the impact that the modified technical writing course has had on the industry.

ON THE USE OF VIRTUAL REALITY TO TEACH ROBOTICS

Marcelo da Silva Hounsell[1], *Alexander Pimentel*[2]

Abstract *-- This article discusses criteria to the use of Virtual Reality (VR) for engineering and computing teaching, in particular the teaching of robotics (robots anatomy, functioning and off-line programming). How a web-based VR system for teaching purposes has been implemented will not be discussed but the advantages and potentials that such implementation can bring to the teaching of robotics. These expected benefits will be compared against what was actually achieved considering limitations of the technology as well as human (students') factors and expectations. Therefore, a borderline will be suggested to help identify the suitability of an application to be implemented using a specific VR approach (high-end immersive or low-end non-immersive). It was found that there is a great enthusiasm that surrounds the topic but a lot has to be done in order to find a proper matching between VR and traditional teaching resources, in particular, to the teaching of robotics.*

Index Terms -- Immersive and Non-Immersive Systems, Robotics, Teaching, Virtual Reality.

INTRODUCTION

Robotics and Virtual Reality (VR) are two distinct concepts surrounded by a lot of misconceptions. The former is usually related to intelligent and mobile human-like robots. The later is usually related to computer-generated and visually appealing reproductions of the world, good enough to confuse the viewer and his/her sense of reality. In fact neither of them are at this marvelous stage yet. These understandings however, could be put as goals for the (still distant) future. Despite the confusion, Robotics has been evolving fast as well as VR [4] and it is not difficult to see how the second can help understand the use of the first ([8]-[14]).

Much has been said and researched on the use of high-end VR into education and this has proved very successful ([5] and [12]) despite the fact that it can not be easily widespread to a bigger audience due to costs restrictions. What seems to be very important to investigate is the use of low-profile VR environments into education because these tend to be the entry-level environment that most learners are destined to face in the near future, at least in developing countries.

This paper not only discusses the use of VR for educational purposes but also the requirements and suitability of an application to a specific VR system implementation.

DEFINITIONS

Rescuing Virtual Reality Basics

Virtual Reality is considered the most advanced computer interacting technology which can promote multi sensorial experience and involve the user in such a way that s/he will not bother to acknowledge if it is the real world or a synthesized one. The user involvement with the system is much more important than the graphics which, not always, is trying to model a real environment [11]. Therefore, the term Virtual Reality (VR) was severely criticized and the term Virtual Environments (VE) came later. Despite the fact that the scientific community has accepted the arguments, people in general refuses to use the correct terminology because VR became very popular. It is important though, to the discussion in this paper, to understand the technology's correct goals and definitions.

VR systems can be divided into two main approaches: Immersive VR (**IVR**) and Non-Immersive VR (**NIVR**). The distinction is not really related to the ability to promote the immersion sensation but to the use of devices that hides the real world from the user, or not.

IVR imply the use of output (such as a Head Mounted Display - HMD) and input (such as a Data Glove) devices which transfers the user's gestures to the synthesized world. Because of the extra hardware configuration and the need to produce better and fast graphics, the computer power is of high requirement. In addition, there were reports that users of IVR experienced motion sickness and fatigue [10].

NIVR, on the other hand, do not imply any specific hardware beside the existing user's monitor, CPU and mouse. This simplification eases the hardware requirement at the same time that widespread the technology's concepts. Even to graphics, it can be said that NIVR do not need to look good but roughly good; on the verge of the reasonable. In this way, it does not demand much computational performance.

Special cases of NIVR systems are those that can be explored through the Internet and which became feasible much thanks to VRML (Virtual Reality Modeling Language) technology (www.VRML.org). Web-based NIVR is considered a great advantage of Non-Immersive VR over Immersive VR approach. It also allows the use of VR-like

[1] Marcelo da Silva Hounsell, B.Eng., M.Eng., PhD. DCC-CCT-UDESC, Campus Universitário, Bom Retiro, Joinville, SC, Brazil, 89223-100, marcelo@joinville.udesc.br
[2] Alexander Pimentel, B.Sc. DCC-CCT-UDESC, Campus Universitário, Bom Retiro, Joinville, SC, Brazil, 89223-100. Alepmtel@ig.com.br

applications for marketing and collaborative works at acceptable costs. Although Web-based NIVR is much simpler than IVR, it cannot be confused with Simulation softwares. IVR excels in interactivity while Simulation is far the best in accuracy. In most cases, VR needs to **look** accurate, not necessarily to **be** accurate. Table 1, summarizes the differences between Simulation, Non-Immersive VR and immersive VR softwares.

TABLE I

COMPARISON OF SIMULATION, NIVR AND IVR SOFTWARES

Simulation	Based on complex mathematical models, must be accurate Aims at precision and completeness High computational cost for calculations Not very much interactive Useful for detailed analysis via playback
Non-Immersive VR	Based on simpler mathematical models Do not demand much calculations and graphics Aims at interactivity on conventional hardware Promotes immersion by intense interaction Do not need to be correct but, look correct
Immersive VR	Based on mathematical models, focused on the phenomena of study Demands special hardware and high computational costs Allows highly interactive environments Immersion is facilitated by the hardware

While promoting VR, developers are used to convince clients to adopt it based on the benefits and advantages that outcome from high-end IVR implementations. But due to cost restrictions, contracts are usually settled on low or medium-end NIVR implementations, only to end up with frustrated clients. The benefits that can outcome from IVR and NIVR implementations are not fully clarified nor completely identified. Application's features need to be analyzed against the suitability to an IVR and NIVR implementation. What this paper discusses is the actual borderline of potential benefits for different approaches and discusses if it is really interesting to consider VR implementation at all.

EDUCATION AND TRAINING

Another clear distinction that must be drawn is between education and training to help identify the role of VR in this context [11]. The later has found in IVR applications great proficiency and productivity. The former is yet to be proved, although there is a general feeling that many benefits can come from it. Education is related to concepts, knowledge and understanding while Training is related to reflex development, know how to do and, handling skills.

For educational (not training) purposes there must be a pedagogical paradigm to guide the experience and direct the development. Interactivity is the concept that will allow the students to explore the environment which therefore, must be implemented in a way to make clear the knowledge structure and hierarchy and consider all types of pertinent media (text, graphics, animation, video, etc.) as well as when, how and why use that specific media for that specific information. The visuals of a VR application also help build a motivating environment if modeled as interesting scenarios.

For training purposes, the use of the environment is different. Training requires a realistic response to events. Also, a better degree of realism (real time rendering) is also required due to the fact that the sequencing of events should not be compromised or the whole experiment would be also compromised.

The trainee should develop motor skills as well as strategies to solve them problems. To assess the trainee performance it is much more difficult because most of the metrics are based on a mix of strategies and timing.

ROBOTICS FUNDAMENTALS

A standard "robotics fundamentals" syllabus would include: History, Concepts Evolution, Robots Classifications, Anatomy, Kinematics (direct and inverse, Denavit-Hatenberg calculation), Task Planning, Teaching and (off line) Programming [13]. The ideal scenario would be to allow the students to have hands-on the actual robot for some experimentation in order to give them the sense of complexity, to understand the relationship and co-ordination of the robot links movements and hierarchy as well as their response to pitch, yawl, roll and other commands either at joint spaces (Robot coordinate system) or world space (Euclidean coordinate system).

To that aim, schools face the problem of offering enough robots for all students and, at the same time, giving continuous assistance and supervision in order to help the students avoid accidents to themselves and to the robots. This dilemma can be better handled (not fully answered though, as we will see later) if some sort of specific Robot Simulation package is used. However, specific Robot Simulation softwares are very expensive, tailored to a specific robot manufacturer, can not be experienced through the internet, have closed codes that do not allow the students to understand how they work and do not allow them to interfere into the code (for post-graduate students, for instance). An alternative approach must be considered.

GENERAL EXPECTED BENEFITS OF USING RV FOR ROBOTICS TEACHING

Computer graphics as a whole has evolved considerably and has aided a lot on engineering teaching and, VR applications are no exception. The use of a VR approach to implement robot simulators could be very training effective. For instance, McLachlan [8] has developed a NIVR robot simulator that paid special attention to the interface: it could be via 3D mouse or by a robot's specific Teach Pendant model. There is a lot more convincing evidence that one can use VR systems for educational purposes ([12] and [14]).

Some of the most significant expected benefits related to the use of VR to teaching robotics are summarized as follows:

Space and Proportion. VR applications can be used very effectively to develop the sensation of space and proportion at the same time that it can be totally non-dimensional as it can model and present galaxies in the same way it can show molecules and atoms. Robots are composed of articulated limbs that reach objects within a specific working volume. A working envelope is a spatial and proportional feature of all robot's limbs working together.

Automatic Monitoring. As an educational aid, a VR application must offer a way to assess the experience automatically and this can be made explicitly and textually via direct questioning but also by monitoring all the interactions implied by the user to achieve his/her tasks. Continuous monitoring not only guarantees the contents understanding but also help on their apprehension.

Scenario Variability. The option of various scenarios is a must in case of training because the trainee must be able to perform consistently despite of the details of the experience. To that effect, the system should be able to automatically construct different situations intelligently and with a high degree of integrity to what is being learnt, promoting both variety and quality. For educational purposes there is the same requirement but it is because of the boredom of unchanging environments.

Availability. Simulators as a whole (including VR ones) are much cheaper than the actual apparatus and because of this can be much more available. Details that contribute less or nothing to the actual operation can be filtered out of the virtual environment and installing a software is, most of the time, a much easier task than installing a complex, big and expensive machine (those that are complex enough to justify an exhaustive, detailed and rigorous training program).

Security. Security issues are one main advantage of using a VR approach at all. Not only the equipment and the whole investment are protected from misuse and accidents but also, the students' integrity are guaranteed. Other real and specific security measures can be imposed by the system, making sure that the student get used to them before going after the actual robot and, even better, this can also be assessed automatically and individually by the system. These features are considered of much importance because they relate to attitudes before the technology.

ACTUAL BENEFITS

A Web-based NIVR robot simulator implemented. Particular interest has been paid to allowing off-line programming, not yet fully implemented though. The technology applied was Virtual Reality Modeling Language (VRML).

Handling Proficiency. It was found that a Web-based NIVR robot simulator could help the student get acquainted with the interrelationships between the robots limbs. Students explore and start to develop strategies to get around fast in order to complete a task. This exploration allow proficiency on controlling the robots movements one degree-of-freedom (DOF) at a time and this is very useful for a later Teach Pendant programming task.

Open Source. One very important feature of the Web-based NIVR approach is the fact that the students can have free access to the source code of the VRML implementation and thus, they can investigate how the calculations are performed but also, they can modify the code to comply to new situations on teacher's demand. Further, the code can be re-used and fine-tuned to more complex models (with an extra DOF, for instance).

Supervision. Although thought unnecessary to supervise the students on performing a task, it was found later that some students feel more comfortable to have the teacher's continuous assistance and to do this, a Web-based NIVR approach can also be useful because it allows various students to get together in a lab and the teacher to assist all of them at the same time.

Strategies. Better than simply allowing off-line programming, which is a reasonably simple task if compared to computer programming, exhaustive repetition of the same experiment allows benefits that resembles a training approach. Beyond this, due to the high availability of the "virtual robot" the student can be freed of the pressure to complete a task but concentrate on establishing better strategies to solve the task. Strategies usually come from a lot of experimentation and experience and are difficult to teach because it is a complex mental model on how to solve a problem. To that aim, a Web-based NIVR can be very helpful.

PROBLEMS FOUND

Analyzing the actual use of the Web-based NIVR robot many problems can be pointed out:

Expectations. NIVR are not up to the user's expectations standard (built upon distorted concepts that came from science fiction novels). Although useful, NIVR approach would not substitute "the real thing" because they lack the ability to involve the user in such a way that can promote an effective immersion. This is so because the environment in focus does not actually provide, and is not much interested, in the exploration or navigation resource once the object of study is a fixed location object (manipulator robot).

Visuals. The visual fidelity was not an issue at the beginning because it was understood that "RV is not really about perfect graphics and perfect visual aimed to confuse the viewer but RV is actually an interactive technique demanding satisfactory graphics that could transport the user to another world" ([3] and [11]). In addition, as the object of study is fixed to a position this also compromises some of the great benefits advocated to IVR: exploration. Therefore, as the user's attention is most of the time focused on a specific object (robot), the visuals start to become an important issue.

Timing. The robot that was implemented did not actually take the time that a real robot would take to move about. This was thought as an advantage at the beginning because it could speed up the experimentation process and analysis. However, the sense of mass and fast/slow response was found to be an important information to be embedded in the virtual robot in the same way that a giant do not move about so fast and that a dolly lady has a high-pitch voice, which are well established 3D character animation features that brings real live constraints to viewers subconscious [7]. Fast-forward simulations go in the opposite direction of those well-accepted and mature ideas from 3D character animation. This could give the students an extra and important information: common sense relationship between inertia and movement. Also, students would value the fact that robots do not respond as fast as they want and that inertia and other physical phenomena are controlling the robot movement.

Despite of the virtual environment, students have shown interest in using the actual robot, maybe because of the limitations of a Web-based NVR approach that is not really very suitable to develop a proper perception of mass, proportion and dimension.

Cost-benefit analysis. The enthusiasm on VR applications has diminished the need of a proper cost-benefit analysis. It must be said that there are a lot of situations where the use of the "real thing" is feasible and cost-effective or where other cheaper techniques can be very appropriate [2].

Care must be taken because VR has been considered as a "silver bullet' for every graphical application. This is also a misconception but VR potentials must be recognized. VR is a good alternative if one of its basic concepts (immersion, interaction and imagination; [3]) is effectively implemented or if, preferably, all of its concepts are thoroughly explored. However, we have found many applications where **some** of VR concepts are roughly explored. This unsuitable and unmatching attempt raises the questioning not only on the applications of VR to that specific application but also on VR as an interesting and feasible aid to teaching at all.

No methodology. It is worrying to find that, although some claims have been made on new methodologies targeted on developing VR applications ([1], [6] and [9]), no specific development methodology targeted could be found. A specific methodology would emphasize and maximize the potentials of VR concepts (immersion, interaction, navigation and exploration) in the same way that it would exclude graphics-oriented-only applications. Even more, if no specific VR development methodology were found, one can tell how difficult it could be to find a methodology that comply to a sound teaching-learning paradigm and, to our knowledge, no pedagogical-didactical theory yet have suggested the use of VR as an inherent medium.

Therefore it is still important to discuss how VR can be used for educational purposes, what sort of content's features could be better valued on a NIVR or IVR approach. This paper aims to bring some findings into this discussion.

It seems promising to borrow and adapt methodologies from web-sites design and multimedia development to build NIVR applications because there are some similarities.

TABLE II
MATCHING OF VR APPROACHES TO APPLICATION'S FEATURES

Feature	NIVR	IVR
User need to alter the source code for free experimentation	++	--
Availability through the internet/ Can be used for distance learning	++	--
Allow collaboration between students (Taxen:594)	++	--
Cost effective	++	--
Availability of "developing methodologies"	++	--
Single fixed object of study	++	--
User need to interact with textual media (access and run an off-line program, for instance)	++	--
Interactivity	-	++
Sense of Immersion	-	++
Allow eavesdropping supervision/monitoring	++	--
More than one user at a time in the same room	++	--
Requires better graphics and realism	++	+
Motivational Environment	+	++
Facilitate interaction with "the real thing"	-	++
Need to develop skill related to proportion and dimension	--	++
Resembles science fiction devices, which raises the user's (misconceived) expectation	--	++
Resembles simulation packages, which raises lower expectations	++	-

Because of this NIVR applications development is closer to mature into a more adequate tailored methodology if compared to IVR applications.

Table 2 shows of the application's characteristics highlighted above together with others and the suitability of them to be better implemented as an IVR or a NIVR approach. The sign "++" indicates a feature to be most suitable to that specific VR approach while "--" indicates that it is not really suitable to that approach.

CONCLUSIONS

This paper has briefed robotics and virtual reality (VR). VR systems have been divided into two main approaches (immersive - IVR - and non-immersive - NIVR) and these have been compared altogether with simulation softwares. It was highlighted that a big gap exists between NIVR and IVR systems in a way that the first is tied to simulation or video game standards and expectations while the last is much more productive but requires a much better financial background.

It was found that some high expectations exist by the audience due to misconceptions broadcast through science fiction films and novels. These expectations are even farther from reality if considering a NIVR approach. The tricky business is to morph expectations into a motivational drive in a way to avoid frustration instead.

The paper have shown potential benefits of an IVR and of a Web-based NIVR approach which were then discussed against actual benefits. A comparison of these benefits have shown clearly that a big gap exists between them and a clear borderline can be drawn to the suitability of one approach to achieve an specific application's feature.

Despite great advantages, VR do not give students the confidence to play with the real thing and some skills (mainly related to the equipment and its surroundings security) need to be further developed. It is believed that students have shown interest in using the actual robot because of the limitations of a Web-based NIVR approach that is not very suitable to develop a proper perception of mass, proportion and dimension.

Researchers are still exploring development methodologies that could be adequate to VR applications, in the way that it assess the fitness of the application as well as matches and emphasizes the conceptual framework backing VR: immersion, interaction, navigation, involvement.

It can be finally concluded that a Web-based NIVR approach to develop an application to teach robotics is an ideal tool because it is cheaper, more easily available and allow more intensive trial and error use of the concepts. Also, the basics of robotics seems to be better explored if using an IVR approach while programming seems to be better implemented if using a NIVR approach and, valuable benefits outcome from both approaches that suffices to maintain the enthusiasm on using VR to teaching robotics.

ACKNOWLEDGMENT

The authors would like to thank Rudimar Anor Zwirtes for his valuable comments and contributions to this research and UDESC for the grant to develop the VRML Robot Simulator prototype.

ANALYSES OF CURRENT METER DATA IN THE COASTAL AREA OF SAO PAULO STATE (BRAZIL)

Joseph Harari[1] and Alexandra F. P. Sampaio [2]

Abstract — *Oceanographic measurements in the coastal area of Sao Paulo State (Brazil) were obtained by using an Acoustic Doppler Current Profiler (ADCP). Nine records of approximately one month each (in 1998 / 1999) are relative to 7 positions, with local depths ranging from 13 to 33 meters; the sampling rate was 15 minutes, from 5 meters below the surface up to 5 m above the bottom (typically), at 1 m intervals. The current meter data were submitted to analyses, in order to obtain information about the circulation characteristics in the coastal region. For every point and at every depth, time series of east-west and north-south current components were analyzed, giving basic statistical parameters (mean, median and extreme values, standard deviations, histograms, polar histograms, progressive vectors) and spectra (of amplitude, energy and rotatory). The analyses will provide an important support to several environmental issues in the region, such as water quality and pollution.*

Index Terms — *Current meter data, ocean circulation, time series analysis, Sao Paulo State coastal area (Brazil).*

INTRODUCTION

The ADCP (Acoustic Doppler Current Profiler) is formed by three or four acoustic transductors fixed under the ship (or deployed at the sea bottom); they are oriented in different directions and behave like transmitter-receiver.

Signals are emitted towards the bottom (or the sea surface), with a 30° angle to the vertical, being reflected by micro-organisms and particles suspended in the water; the acoustic transductors receive the reflected signals with a change in their frequency, proportional to the particles radial speed (Doppler effect). A sampling of time enables to calculate the Doppler changes in layers of water evenly matched in depth.

Then, the grouping of the signals enables to obtain a representation of the speed of the ship against each layer of water (or the speed of the layers relative to the sea bottom). Emission frequencies are between 38 to 150 KHZ with respective ranges between 1000 to 4000 m. The delivered data are speed and direction of the layers of water (with typically 1% accuracy).

Present study is relative to ADCP´s moored in the ocean floor, at 7 positions in the coastal area of Sao Paulo State (Figure 1), giving 9 records of approximately one month each, in the period of 1998 / 1999. These positions have depths that range from 13 m (point 6) to 33 m (point 5) and the observations were from 5 m below the surface up to 5 m above the bottom, at 1 m intervals, with sampling rate of 15 minutes.

The analyses of the time series generated by the oceanographic observations will provide an important support to several environmental issues in the coastal region of Sao Paulo State, especially pollution and water quality control.

METHODOLOGY

The time series of current meter data were obtained for each point and depth by decomposing the intensity and direction values into east and north components.

The time evolution of the current components was initially represented graphically and then submitted to statistical and spectral analysis, using software developed for the mathematical package Matlab (1999).

The basic statistical parameters computed for each series were: mean, median and extreme values, standard deviations, histograms, polar histograms and progressive vectors. In the frequency domain, spectra of amplitude, energy and rotatory were obtained (Jenkins & Watts, 1968).

RESULTS

A selection of results will be presented, relative to point 5 (24° 15.056' S 046° 17.076' W), at the depths of 5 and 28 meters, with observations in the period from 29 January 1999 18:00 to 19 February 1999 14:15 (local time).

Figures 2a and 2b present the stick plots of the daily mean currents near to the surface and the bottom, respectively, considering 20.5833 days of measurements: the currents are quite homogeneous along the vertical, being mostly to Northeast but with some observations to the Southwest. This feature is confirmed by the correspondent polar histograms, shown on Figures 3a and 3b, which give the number of observations in each direction.

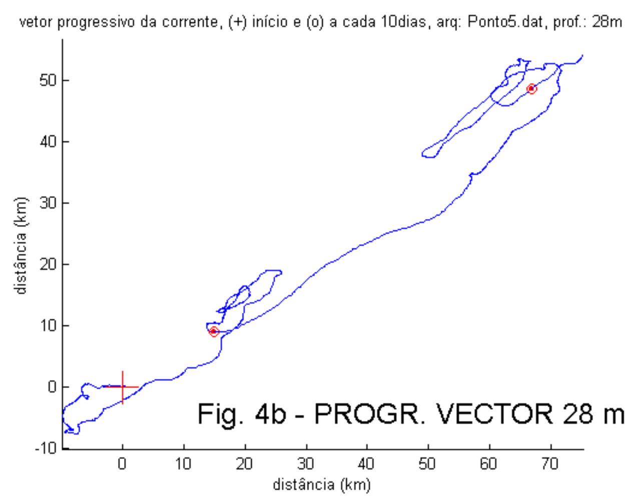

Fig. 4b - PROGR. VECTOR 28 m

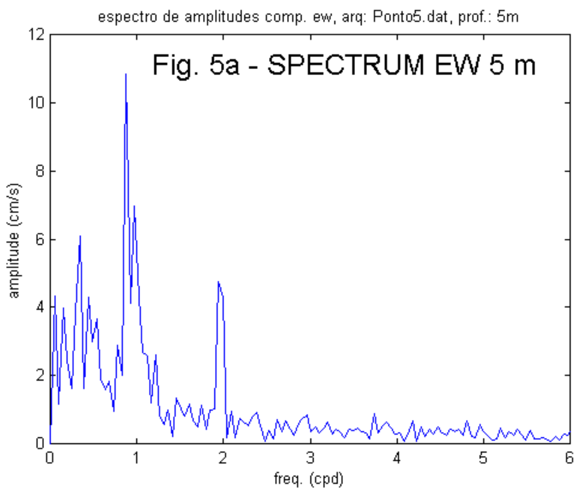

Fig. 5a - SPECTRUM EW 5 m

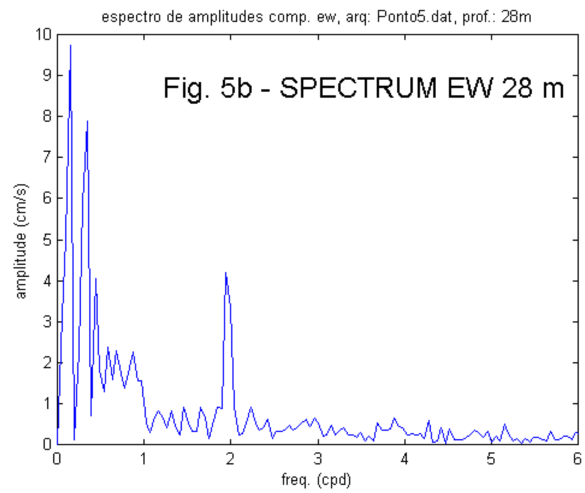

Fig. 5b - SPECTRUM EW 28 m

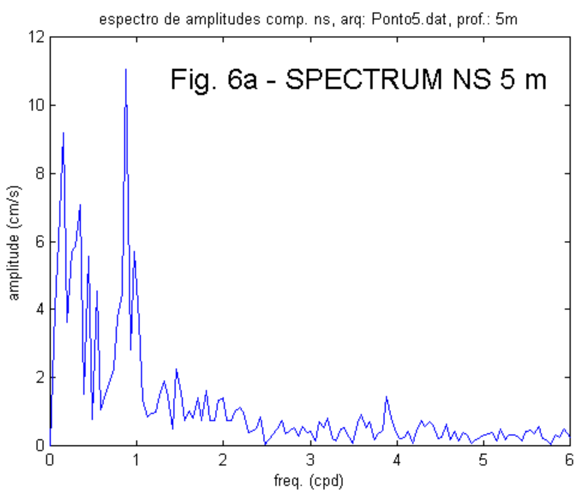

Fig. 6a - SPECTRUM NS 5 m

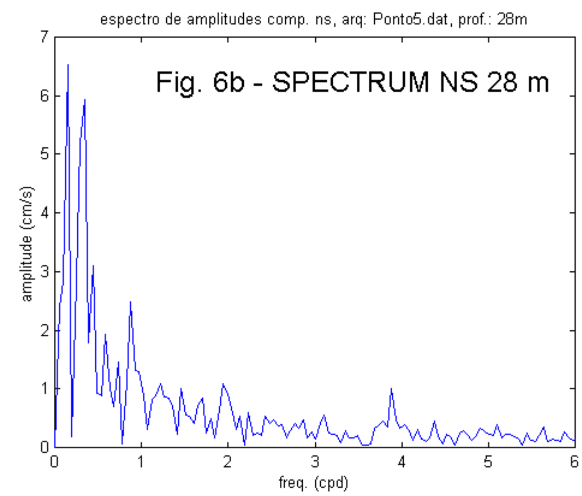

Fig. 6b - SPECTRUM NS 28 m

Figures 4a and 4b show the progressive vectors near to the surface and the bottom, considering samples at every 15 minutes, both with resulting values to the Northeast

The spectra of the current components are given in Figures 5 and 6, again considering the observations at 5 and 28 m depth. These figures show important differences between the surface and the bottom circulation. In the EW direction, long period components (with frequencies below 1 cpd) are energetic at the bottom and much weaker at the surface; on the other hand diurnal components (around 1 cpd), are stronger at the surface and nearly disappear at the bottom; finally, semi-diurnal current components (2 cpd) are nearly constant from the surface until the bottom. In the NS direction, long period components are significant both at the surface and bottom, the diurnal components are damped at the bottom and the semi-diurnal ones have small amplitudes.

The basic statistical parameters relative to 5 and 28 m depth, for the velocity intensities and EW, NS components are given on Table 1, which indicates that both mean and extreme values are stronger at the surface.

These circulation features agree with other publications; particularly the expressive decay of the diurnal components and much smaller one of the semi-diurnals were also observed in other current time series of this continental shelf, such as the ones of Mesquita & Harari (2000, 2001).

CONCLUSIONS

Present study shows recent developments in coastal Oceanography and Engineering, both in observations and analyses, with the use of automatic sensors for high quality field measurements and quick analyzing procedures.

The ocean circulation characteristics inferred by these analyses may be used in several applications, such as numerical predictions, navigation security, coastal protection, sedimentation, erosion and water quality control.

TABLE 1
BASIC STATISTICS OF OCEAN CURRENT DATA
(POSITION 5)

5 m depth	Values in cm/s		
	Velocity	EW comp	NS comp
Minimum	1.0	-47.0	–32.7
Maximum	65.0	49.6	61.4
Mean	22.5	4.4	6.3
Median	21.0	4.8	5.3
Standard deviation	11.8	16.0	18.1

28 m depth	Values in cm/s		
	Velocity	EW comp	NS comp
Minimum	1.0	–28.4	-26.5
Maximum	46.0	41.7	31.4
Mean	15.4	4.2	3.0
Median	14.0	4.1	3.9
Standard deviation	8.2	13.3	10.2

Napkins, Knives, and Forks: Etiquette Education at the University of Cincinnati's College of Applied Science

Linda Ginter Brown[1]

Abstract--*When students finish their degrees they have mastered certain levels of expertise in their chosen disciplines. However, an important gap exists in their knowledge base. These students often lack the requisite social skills (etiquette knowledge) to successfully climb the corporate ladder. Professionals in business and industry know that how they look and act in social settings often determines the level of success they achieve in their organizations. This report describes the results of a course developed at the University of Cincinnati's College of Applied Science to teach business etiquette to engineering technology students. The course covers subjects employers confirm as crucial to successful entrance into the corporate world. Units such as appropriate business dress, proper table manners, proper introductions, telephone use, and how to conduct business in another country are covered. Examples of problems to help students analyze and apply etiquette knowledge are also included.*

Index Terms—business etiquette, international protocol, table manners, social skills

In contemporary society, technology reigns. Palm pilots rule. Cell phones abound. American society, and others as well, operates around the clock. We eat fast food, drive fast cars, and we have the ability to conduct business 24 hours a day. We skimp on sleep, electing instead to rise early to exercise before work. We speed to our jobs while gulping down coffee or some fast food item purchased at the drive-thru. After work, we rush home to a quick dinner, ferry the children to various activities, and arrive home dead-tired, although we still have email to answer before falling into bed. The next day we do it all over again. People are continually in a hurry, multi-tasking themselves into oblivion. Is it any wonder that nerves are frayed and that many people find themselves operating "close to the edge"? In the aftermath, politeness and courtesy, civility if you will, often get left behind.

The media report stories such as the woman who became enraged when the customer in front of her at the check-out line exceeded the 12 item limit. She actually followed the woman to her car and began to beat her. Or the out-of-control man who was cut off in traffic by another driver. His anger was so great that he jumped from the car and pulled the woman's little dog from the car window and flung it into traffic to its death. Extreme examples you say? Perhaps. Yet, they reflect the attitude and lack of self-discipline some folks exhibit on a daily basis. As tragic as these examples are, they happen because some one chose to ignore the code—the proper protocol. People violate protocol every day.

Yet protocols hold our society together. Even technology functions within them. Consider the computer. It won't function properly, if one doesn't follow the proper protocol for booting it up and letting it check the internal system. Even machines have to follow rules. Likewise, society needs rules to function properly. Rules of behavior are nothing new. As Dorothea Johnson, C.E.O. of the Protocol School of Washington, notes: "Protocol has been observed since the ancient Egyptians produced the first known book,

The Instructions of Ptahhotep. Along with the plow and the twelve-month calendar, they invented manners…The term 'protocol' is derived from two Greek words, protos, meaning 'the first' and kolla meaning 'glue'…Today, the word protocol serves as the code of international politeness that blends diplomatic form, ceremony, and etiquette"[1]. Just as protocol or etiquette serves as the "glue" to hold society together in positive ways, etiquette smoothes the way for successful relationships in the corporate sector. College graduates who display knowledge of business etiquette have an edge over those less-informed. As Lillian Chaney, points out "Schools, particularly institutions of higher learning, must convey to students that good manners are essential to climbing the corporate ladder" [2].

At the University of Cincinnati's College of Applied Science we've addressed this need. Our students earn baccalaureate degrees in various fields of engineering technology. In addition to their technical courses, our students study professional communication, both spoken and written, as well as ethics. Recently, we've added an entire course in etiquette to our curriculum, "Global Civility" (Civility and Manners for the Global Age). I developed this course last year in response to industry's request. Our graduates have fine technical knowledge, both theoretical and applied, but they often lack knowledge in the social graces.

I've taught this course twice now, and the response has been overwhelmingly positive. Students are enthusiastic and appreciate the opportunity for such a course. Our local paper, *The Cincinnati Enquirer*, wrote an article about our final dinner exam, and the Associated Press picked up the

[1] Linda Ginter Brown, Department of Humanities, Media and Cultural Studies, College of Applied Science, University of Cincinnati, 2220 Victory Parkway, Cincinnati, OH 45206, U.S.A., Linda.Brown@uc.edu

story. Ever since, calls and emails continue to arrive daily. The BBC even called to request an interview. Manners matter. People have an interest in the course. The need exists, and others recognize it as well.

The course covers areas personnel managers deem necessary in order to advance to managerial levels. These areas include:

- Making introductions properly
- Using proper table manners
- Managing social functions
- Dressing appropriately
- Showing thoughtfulness by responding to invitations, writing thank-you notes, sympathy notes, and notes of congratulations and appreciation
- Speaking correctly (grammatically)
- Using the telephone properly (including cell phones)
- Conducting business in another country

The course meets twice a week, for 75 minutes each class period and is highly participatory. It culminates with a final dinner exam at one of Cincinnati's finest upscale French restaurants. I begin the course by discussing the concept of civility. We talk about what it means to behave as a civil person, and why it is important to the concept of professionalism. I introduce historical examples such as one Dale Keiger noted from the

Galateo, in 1558, 'Nor is it seemly, after wiping your nose, to spread out your handkerchief and peer into it as if pearls and rubies might have fallen out of your head… What, then shall I say of those…who carry their handkerchiefs about in their mouth?" [3] Others include George Washington's translation of *Rules of Civility & Decent Behavior In Company and* Conversation circa 1744 [4] and Margaret Visser's work which notes that "every human society without exception obeys eating rules, what ritual is and why we need it at dinner (cannibalism, for instance, is found to conform to strict laws and controls); and the meaning of feasting and sacrifice [5]. Then we move into subjects such as dining skills. We cover things such as proper napkin use, posture at the table, how to excuse yourself, and proper dinner conversation.

Throughout the first half of the course we practice proper handshakes, introductions, giving and receiving toasts, and we also discuss what constitutes proper business dress in the contemporary corporate arena. I've written problems to help students think critically about what it means to apply business etiquette knowledge in the workplace. One problem focused on the duties of a host who entertains a visiting dignitary:

PROBLEM

You are a recent graduate with a degree in Mechanical Engineering Technology, and you have been working nine months at Triton Steel Corporation. Your boss tells you he has big plans for you. He informs you that you will host a dinner at the Shady Nook Country Club in honor of Mr. Tren Wong, an executive from Singapore. What do you know? What do you need to know?

Students research the various duties of a host. One student wrote, "I made arrangements with the country club for our company to pay for the event and to reserve enough table space for our party of 12 people. I gave the names and ranks of individuals attending to organize the seating arrangement. Singaporeans feel an even number of guests is a sign of good fortune. The seating arrangements were set up in a hierarchical manner, for this is standard protocol in Singapore. Obviously, removing our shoes will not be a part of this dining event for we are in America… I have been practicing my toast, '*yam seng*,' meaning 'bottoms up' to further impress our colleague. We will be toasting all of his hard work and dedication to our fine company these past 10 years." When I developed the problem a bit further and asked them to assume the duties of the guest of honor, another student wrote," I know that I do not drink when toasted as the guest of honor. I also know that I will need to give a short heartfelt acknowledgement and thank you to the guests and especially the host. Therefore, after the toast is given I will stand and say the following: Thank you all very much. I am very happy to be here this evening. I would like to give my appreciation to our distinguished host, Mr. Smith, for his work putting this dinner together for us. You have all been very kind and generous. Thank you all, and thank you, Mr. Smith."

Another problem focused on rampant cell phone use:

PROBLEM

Your boss, Rhoda Finkelstein, has had it with the proliferation of cell phone use at your company in particular and society in general.

She wants to inform employees about the proper and improper use of cell phones. She tells you she wants you to write an article for the employee newsletter which gives the proper etiquette involved with cell phones. You, Pat Woodward, are a bit taken aback. You can't tell her that you're a cell phone junkie yourself. You adore your cell phone. You talk on it as much as possible, even while driving, shopping, and in restaurants. You find it an amazing tool. Yet Ms. Finklestein is your direct supervisor. What kinds of information will you put in the article? Who will your audience be? Write the article.

One student noted in his paper, "Rage against cell phone abusers is quickly rising thanks to the many discourteous users. The novelty of someone having a cell phone has worn off now that the phones are so common… let your ears cool off once in a while…NEVER let the phone ring during a movie, wedding, or funeral. This is the quickest way to bring your own funeral."

PROBLEM

Another assignment includes writing a note of congratulations to a colleague who's just been promoted. One student wrote, "Congratulations on your new promotion to District Manager of XYZ Corporation. The hard work that you put in as store manager did not go unnoticed. It's great that you have been given this opportunity, but you will be missed at this location. It will be tough finding a replacement for you here. Congratulations again, and good luck in this new position. Sincerely …"

PROBLEM

This problem proves a bit more difficult for students. They are asked to write a sympathy note, a sensitive situation, to a colleague who's just experienced the loss of a family member. This particular student rose to the occasion. He wrote, "I was sorry to learn about the passing of your mother. I want to share your sorrow, and let you know that my thoughts and prayers have been with you. The love of a mother can never be replaced, but I hope you can take comfort knowing that you have family and friends that care about you. May God be with you and your family during these difficult times. Sincerely..."

Students learn through these exercises that the person who can write an effective personal note is light years ahead of the one who just sends a card with a pre-printed message.

The last four weeks of the term students form groups of four to five members. Each group chooses a country to research and uses the following problem:

PROBLEM

Your boss has just informed you that your company has now landed a contract with Reibold International in (insert name of country), and you will be sending executives there to conduct business. The executives who will be going there have little knowledge about this country, and none has ever visited it. Your boss tells you that you are now the head of the newly formed Business Etiquette and International Protocol Committee. Your committee's job is to compile a document which employees traveling to this country can use in order to successfully represent your organization. What should the document contain?

Students research various topics such as dining skills, gift-giving, gestures, exchange of business cards and topics to avoid. They compile an executive's business guide to that country. During the last week of class, each group gives a twenty minute presentation where they share their findings as well as the final guide. It's interesting to observe some of their reactions such as the group who were surprised to learn that if one is given a gift in Korea, one shouldn't open it in the presence of the giver since to do so is considered rude. Rather, one should set the gift aside for the time being. The same group noted that political conversation might be fraught with tension and that one ought to avoid discussing the Korean War or the Japanese Occupation A member of another group, s first-year female student, was shocked to learn that if she visited Saudi Arabia, she would not have the same freedom to move about as a male counterpart. The group that studied Australia was delighted to discover that it is common practice for Australians to split the bill for business dinners and that tipping at restaurants is optional. They were also relieved to learn that most Australians have never eaten kangaroo meat, a delicacy, so business visitors would probably not encounter it while dining Down Under. Students see how easy it is to offend someone without meaning to do so. They learn to sensitize themselves to the different customs of various cultures.

We end the quarter by reviewing proper business attire and proper dining skills in anticipation of the final dinner exam. Students are excited and understandably nervous. However, without exception they rise to the occasion, and a truly, gratifying metamorphosis takes place. These same students who sat before me with their baseball caps on backwards, wearing their trusty Reeboks for the past ten weeks change into men and women enjoying a business dinner in an elegant restaurant. They have learned important skills and acquired the necessary confidence to make a successful entrance into the corporate world.

MODERN INFORMATION TECHNOLOGIES AND A DREAM ABOUT INDIVIDUAL EDUCATION

Zoia Sazonova[1]*, Nina Chechetkina*[2] *and Tatiana Tkacheva*[3]

Abstract — *The Internet conducted the informational integration of all the countries in the world. Introducing modern information technologies to the sphere of education accelerates the process of the unification of national educational systems. A united international educational environment is being formed. The accessibility of qualitative study information and the existence of an effective system of the educational process management can make our dream of the individualization of education come true.*

Index Terms — Information technology, individual education, pedagogy, management of education, testing.

BODY

The computerization era came to Russia much later than to Europe and the USA.

Just 10 years ago in the Moscow Automobile & Road Construction Institute there were just a few computers. By nowadays the amount of computers has increased by hundreds. Nowadays computers are used in the Russian system of education very intensely.

Lecturers and students of MADI actively use personal computers for various scientific and educational purposes: for instance, to model different processes, to make the control over experiments automatic, to create electronic text-books and so on.

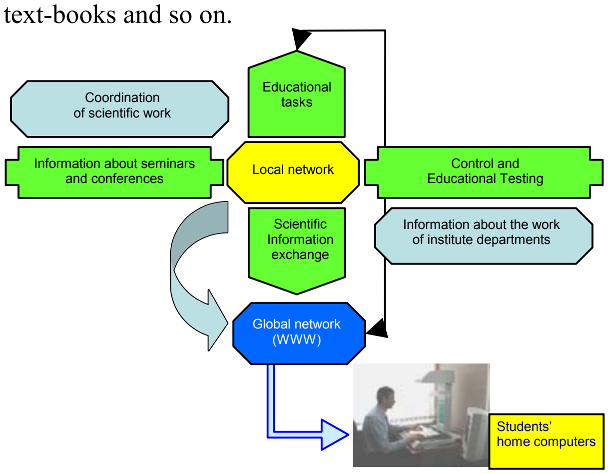

FIGURE 1.

In MADI there is a local computer network (Fig.1). We use it to coordinate scientific work, to get information about the work of institute's departments, to learn about seminars and conferences, to carry out educational & control testing, to give students their tasks and to exchange scientific information.

MADI's local network is plugged into the Internet. Students & lecturers can get to MADI's local network from their home computers via the Internet.

Students use various mathematical packages while performing different calculations. For example, during the exploration of the dependence of oscillations on different parameters MathCAD is especially intensely used (Fig.2).

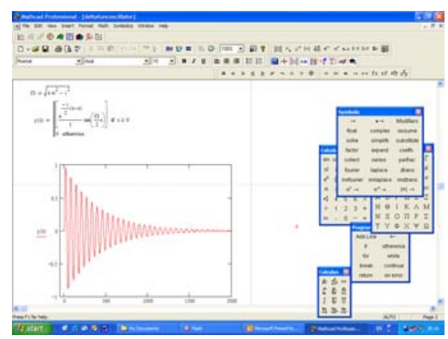

FIGURE 2.

In our university different local systems of testing of the quality of knowledge in different subjects have been

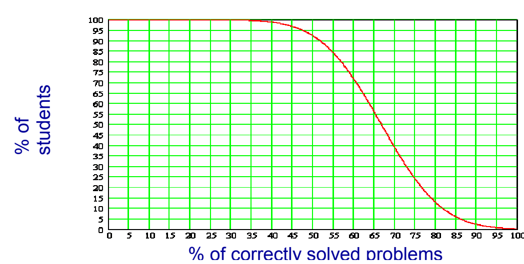

FIGURE 3.

created and successfully used. At this photo you can see students of the 3-rd course, who have just completed one of their tests – they're waiting for the results. The results and their analysis are presented below. The students were to complete 15 tasks. The vertical axis on the graph represents the percent of students, who have successfully coped with some task. We can see that some of the tasks turned out to be difficult for the students. This information is then analyzed and the corresponding parts of the material are then revised in a more detailed way.

Testing is not just a method for controlling the quality of the students' comprehension of the material, but it's also a way of controlling lecture material.

Testing provides us with an opportunity to set a feedback between students and lecturers. The staff of the engineering pedagogy department uses testing as an important instrument in the process of introducing new pedagogical technologies [1,2].

The Internet and a personal visit to England's universities helped us to collect some information about the organization of educational process in Great Britain and the

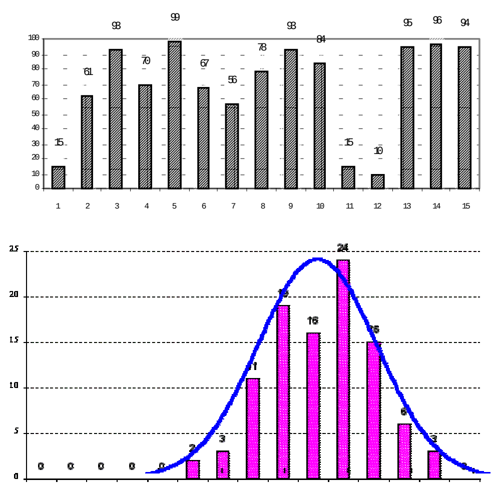

FIGURE 4.

Y-AXIS: PERCENT OF STUDENTS, WHO SOLVED THE TASK

B) **X-AXIS:** THE NUMBER OF SOLVED TASKS
Y-AXIS: PERCENT OF STUDENTS, WHO SOLVED EXACTLY THIS NUMBER OF TASKS

USA. We then conducted a technical analysis of the educational programs of foreign and Russian technical universities. The work carried out by us let us make the following conclusions:

1. Universities of the USA and England have very well developed structures of management of the independent work of the students. Decrease of the number of auditorial classes in these conditions gives positive results.
2. In Russian universities a lot of variants of perspective innovational pedagogical technologies, which take advantage of modern information technologies, have been developed. However, unfortunately, the integrity of the combination of all the conditions, which in all universities can ensure the students' independent work, leaves much to be desired, and the timeliness of the decrease of the number of auditorial classes gives rise to doubts.
3. Study plans of Russian and foreign technical universities have a lot in common, but there are some significant distinctions as well. As an example, we'll consider study programs for the civil engineering specialization in two different universities: in the Imperial College, which is a part of the University of London, and in the Moscow State Automobile & Road Construction Institute.

Foreign programs even on the first two courses already have greater practical orientation than Russian programs do. For instance, in the programs of British universities there's no united course of general physics. Nevertheless, different parts of physics, vitally important for a concrete specialization, are taught in a very detailed way.

For Russian universities very deep fundamental basis is characteristic. Those parts of physics, which are especially important for some concrete specializations, are taught at the so-called "elective" courses. Serious fundamental education provides students with a broad scope and the opportunity to work on the border between different types of scientific or engineering directions.

In the universities of the USA, England and Europe students start working in a team of 5-6 people on their projects already during the first year of study. During subsequent courses this work is continued. It is great when the study process tries to incalculate in the students the ability to work in a team. In Russia the work in this direction is only beginning.

Modern information technologies have created a great deal of new opportunities. The use of modern information technologies in the system of education let us modernize the organization of the study process and give a lot of study time to the students for their independent work in the framework of a well-organized educational structure. Independent work must be manageable.

In order to realize this idea it is important to have an effective structure of management of the process of students' professional development. If such a structure existed, a student could decide himself if he needed to attend lecture classes regularly or if he could work on his own, using those educational materials, which are presented on the web-site of his university.

In this case, when independent work results in good testing score, the student can continue working on his own for most of the time. Otherwise, a student will definitely go to the auditorium. He can sensibly evaluate his abilities and choose his own method of study. Such an approach is respectful towards the personality of a student and can help to solve the problem of education humanization. The creation of an effective management structure of the process of students' independent work is a very important problem. This problem is discussed in the following paper.

CONCLUSION

Modern information technologies let us realize an individual approach towards the education of every concrete student [3]. Every student can optimize his own study timetable himself in order to study in a convenient routine.

Structure of the management of the independent work of the students:

1. A full complex of educational materials required for successful study (in classic and electronic forms)
2. Effective system of constant feedback between students and teachers (Fig.5)

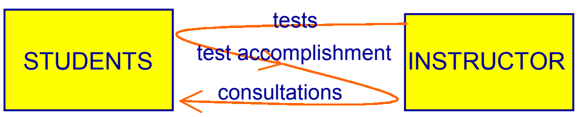

FIGURE 5.

3. System of registration of testing results supposed to support the lecturer marking students' work for the whole course.

ACKNOWLEDGMENT

The authors are grateful to prof. V.M.Prikhodko and prof. V.M.Zhurakovskiy for their interest towards the article and their useful comments.

FLOW AROUND SPHERES: A DIDACTIC EXPERIMENT

Marcelo Ferreira Pelegrini[1] *and Edson Del Rio Vieira*[2]

Abstract *— A steady incompressible isothermal flow past a rigid smooth sphere in an infinitum medium is experimentally investigated for Reynolds number up to 1000 in a fluid mechanics laboratory class. All tests have been carried out in hydrodynamic medium utilizing a water tunnel with 146×146×500 mm of test section, operating by gravitational effect in continuous or blow-down modes, and in a water tank with Plexiglas walls in order to visualize a sphere in free fall in a rest medium. Flow visualization by direct liquid dye injection and hot-film anemometry has been utilized in order to determine, qualitatively and quantitatively, the flow structure and turbulence characteristics in the wake. This proposed experimental activities represent good work opportunities on the teaching process, illustrating several different phenomena relative to the fluid mechanics theoretically discussed in the classroom. The complex measurement made using hot-film anemometry, and the flow visualization images generated, captured and processed directly by student's action in the hydrodynamic tunnel and in the water tank have awaked great motivation in undergraduate students of fluid mechanics.*

Index Terms — Flow visualization, Fluid mechanics learning, Hidrodynamic tunnel, Hot-film anemometry.

INTRODUCTION

The fluid mechanics study, without shadows of doubts, is a complex human activity, with a hard mathematical load and several intricate physical concepts. Traditionally, fluid mechanics laboratory teaching develops several challenges. The choice of adequate experiments to be offered to the students that implicate in better didactic results shows to be an arduous task. Elementary experiments should be offered allied additionally with others more complexes and showing a more elaborated thinking. Nowadays, several new flow didactical experiments, with different degree of difficulty, have been proposed, in technical literature, to be incorporated at fluid mechanics discipline of a undergraduate mechanical engineering course.

The problem represented by a rigid smooth sphere moving into a viscous incompressible fluid far of interference of the walls is a very old engineering problem, utilizing a relatively simple geometry that represents a high degree of complexity. Generally, the understanding of this problem by students is an arduous task and a challenge to the teachers.

Wakes behind a sphere are encountered so frequently in engineering applications implicating in large amounts of research that have been conducted and massive amounts of numerical and experimental data have been accumulated. The studies of the sphere wake that have been done show that the vortex topology and shedding process is significantly different from that found in the well know flow around a circular cylinder. Of course, the wake formed downstream a sphere shows high complexness of the vortex dynamics. This very complex flow exhibits several instabilities with complicated kinematics and vortical interactions and complex flow structures with fully three-dimensional unsteady flow fields in spite of the symmetry of the body.

The experience of the authors in offer the experimental class of a moving sphere in a viscous "infinite" medium to undergraduate students of a mechanical engineering course is reported in this work.

FLOW REGIMES AROUND A SPHERE

The problem of a sphere in movement on a viscous fluid wake up the attention since the Middle Ages due to interest in the cannon balls ballistic problems. The authors recommend the reading of the refs. [1,2] about the problem of the free fall of solid bodies to provide a historic understanding of this problem, including the happens of Galileu Galilei and the Pisa Tower.

The Reynolds number, $Re = \rho\, V\, D\, /\, \mu,$ – based in the no perturbed upstream velocity (V), the sphere diameter (D) and the cinematic viscosity (ν), represented by ratio between the dynamic viscosity and the density ($\mu\, /\, \rho$) – can be used as a primary parameter to classify the flow around a sphere. The flow regimes for a single sphere in a infinitum medium, can be described, in accord to ref. [3] as follows:

For Re < 5, in very small Reynolds numbers, a creeping motion is observed and in this region the flow is governed by viscous forces and no detachment appreciable is observed. These forces are proportional to the product of the viscosity, velocity and diameter of the sphere. In this situation, the Navies-Stokes differential equations can be integrated by neglecting the inertial forces. Stokes, in 1845 was the first in solved they for the case of the sphere,

[1] Marcelo Ferreira Pelegrini, São Paulo State University – Unesp – Ilha Solteira, Av. Brasil Centro, 56 15385 000, Ilha Solteira, SP, Brazil, marcelo@dem.feis.unesp.br
[2] Edson Del Rio Vieira, São Paulo State University – Unesp – Ilha Solteira, Av. Brasil Centro, 56 15385 000, Ilha Solteira, SP, Brazil, delrio@dem.feis.unesp.br

considering the complete boundary condition of no tangential velocity of the fluid along the sphere surface.

For 5 < Re < 130, the wake forms a steady recirculating eddy of axisymmetric ring shape. In this flow regime occurs a flow detachment and the detachment angle (θ) can be accuracy measured in function of Reynolds number.

For 130 < Re < 300, a wave-like laminar wake of very long period forms behind the sphere.

For 300 < Re < 420, a hairpin vortex begins to shed and a spectral peak shows up in the unsteady velocity spectrum.

For 420 < Re < 480, the shedding of the hairpin vortices becomes irregular. This is the early transition regime.

For 480 < Re < 650, the shedding mode is a continuous state of randomness, or irregularity.

For 650 < Re < 800, The shedding pattern differs from that of lower Reynolds numbers due to pulsation of the vortex sheet. Multiple frequencies can be observed and the shed vortices begin to show signs of turbulence.

For 800 < Re < 3 000, some of the vortex tubes formed by the vortex sheet separating from the sphere surface enter into the vortex formation region, while others are shed in small vortex loops. The large-scale vortices move away from the sphere rotating at random about an axis parallel to the flow through the center of the sphere. The wake becomes turbulent at Reynolds near 2000.

For 3 000 < Re < 6 000, This is other transition region where the measured low-mode vortex shedding frequency decrease rapidly with the increasing Reynolds number. The power spectrum of the fluctuating wake velocity shows one characteristic peak plus considerable broadband energy on both sides of this peak. The vortex sheet is changing from laminar to turbulent in this regime.

For 6 000 < Re < 370 000, the separated vortex sheet is now completely turbulent. The vortices shed from the formation region become stabilized because the separated shear layer is no longer laminar, but turbulent. This stabilization causes the velocity fluctuation spectrum to lose some of the broadband nature observed in the previous region. The Strouhal frequency of regular shedding increases with Reynolds number and then approaches the constant value of 0.19 at Reynolds near 20 000.

EXPERIMENTAL APPARATUS AND METHODS

In this effort of work, two different apparatus have been proposed both operating in tap water medium. The first, a water tank all made of Plexiglas of 0.127x0.127 m in cross-section and 1 m in height was used, depicted in Fig. (1).

A small plastic sphere is painted with an adequate color dye and launched from rest in the water surface. The sphere falls freely in the quiet water medium. In few centimeters run, after the sphere launch, the terminal velocity is rapidly observed. The terminal velocity is determined measuring, with help a hand chronometer, the time necessary to the sphere to move between two black adhesive tape, positioned externally on the Plexiglas wall, separated by a vertical known length (L), showed in the fig. (1). The relative water movement slowly dissolves the fresh dye permitting the wake visualization.

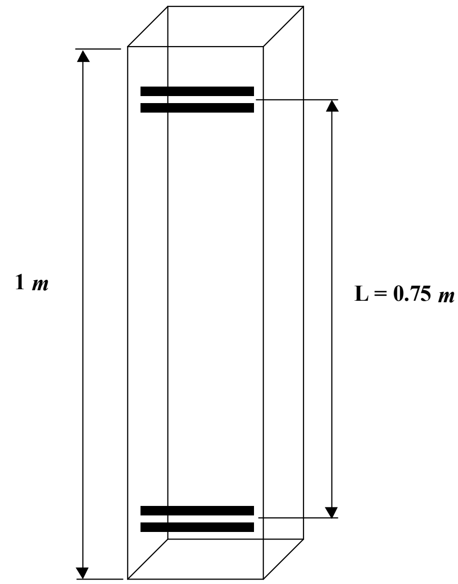

FIGURE. 1
WATER TANK FOR ESFERE WAKE VISUALIZATION.

In order to keep the water still careful attention was paid. Small variation in external air temperature causes water movement due to buoyancy effects provoked by temperature gradient between the tank wall and internal water.

In this device, plastic spheres with approximately 6 mm of diameter were utilized. These plastic spheres are the same utilized in toy guns and they are very cheap and available in toy store in large quantities. Necessarily, each sphere needs to be carefully separated in order avoid the use of egg-shape spheres in the experiment. This separation process can be easily performed with help of an inclined plane. Each individual sphere need to be carefully measured due to a large variation observed in the diameters and in the mass from sphere to sphere. Plastic spheres have internal small air bubbles. This micro-bubbles represent a large variation in the density implicating also in a need to be separation as function of they density.

In order to promote the density classification of the spheres, first of all, take a glass beaker, with one liter of clear tap water, at room temperature. Put a lot of spheres into the beaker. The spheres with density less than water, due to buoyancy force will float. This light spheres can not be utilized, but a large number of spheres remain on the bottom of the beaker. In this moment, you dissolve approximately 25 g of a salt (sodium carbonate, for example) in the water and wait a minute. Some spheres should float on the water surface. These spheres have a density very close with the tap clear water density, and they will produce the better results in the proposed experiment, because the free fall velocity will be very small, producing moderate Reynolds number – up to 700 –, adequate to photographic capture using ISO 400 chemical films.

In order to promote the wake visualization the spheres are painted with a PVA dye. The spheres are launched with wet dye paint. The sphere movement in water provokes the wet dye dissolution permitting the wake flow visualization. An adequate illumination using cold lamps is required for image capture in order to minimize the buoyancy effects due to thermal gradients. This flow visualization process is the same utilized initially in the ref. [4].

The second apparatus utilized to the study of flow around a sphere is a vertical pilot hydrodynamic tunnel device. This equipment, made for research purposes, has been intensely utilized with success for didactical applications, see ref. [5,6,7]. Hydrodynamics tunnels are important tools for didactical purposes using flow visualization techniques. A sketch of this experimental apparatus is depicted in fig. (2).

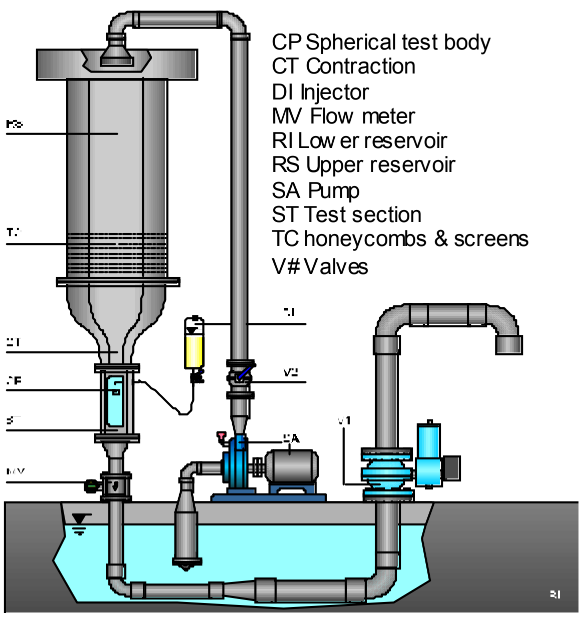

FIGURE. 2
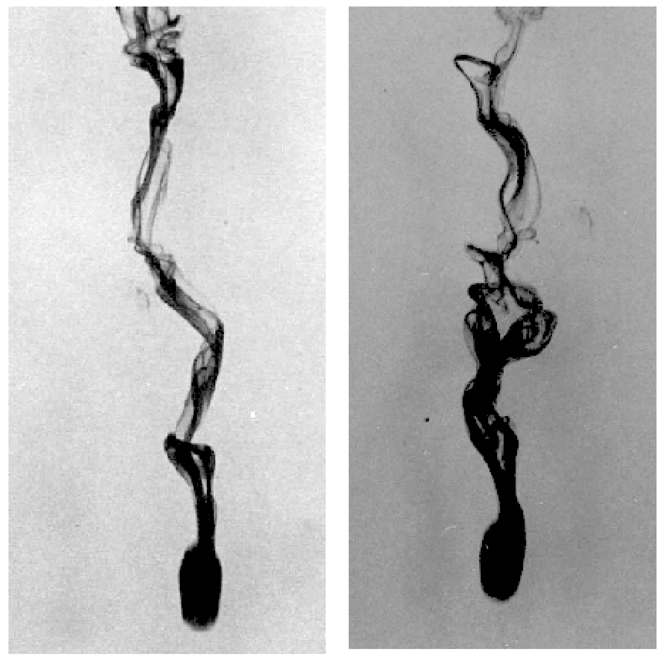
LOW TURBULENCE VERTICAL HYDRODYNAMIC PILOT TUNNEL.

A detailed description of the tunnel operation can be obtained in ref. [8]. A plastic smooth sphere with 35.5 mm of diameter, the same utilized in roll on deodorants, is adequately fixed in the tunnel test section. A long hypodermic needle with 0.7 mm OD permits the liquid dye injection in order to allow the flow visualization. Utilizing this technique the detachment angle (θ) is measured from a processing of the visualized images. These images have been captured utilizing a Sony CD digital camera with only 1 200x1 600 pixel. A digital constant temperature anemometer using 55R11 Dantec probe was utilized to measure the turbulence intensity level in the wake. Details of the anemometer device are found in Ref. [8].

RESULTS

Initially, we will show the result regarded to the water tank. The wake-visualized images showed in Fig. (3), illustrate two different Reynolds regimes.



Re = 440 Re = 532

FIGURE. 3
SPHERE WAKE IMAGES CAPTURED FROM THE WATER TANK.

A terminal velocity (*Vt*) behavior as function of the Reynolds (Re) is depicted in the Fig. (4)

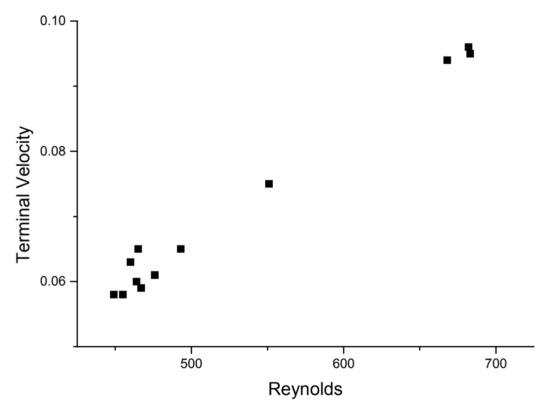


FIGURE. 4
TERMINAL VELOCITY (*VT*) FOR A SPHERE.

The sphere drag coefficient (C_D) – expressed in terms of the ratio between the drag force and the kinetic energy ($0.5\ \rho V^2 A$) – can be also obtained in the same experiment using the water tank. Illustrative results of the drag coefficient is depicted in Fig. (5)

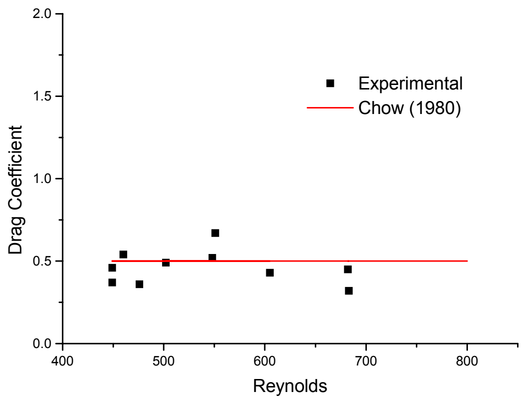

FIGURE. 5
DRAG COEFICIENT (C_D) OF A SPHERE AS FUNCION OF REYNOLDS.

In order to obtain the results relative to the hydrodynamic tunnel can be attacked firstly by the hot-film probe calibration problem. Several methods have been described in technical literature for probe calibration utilizing several different techniques. For example, ref. [9] shows a complete laboratory class utilizing a free jet in order to introduce hot-wire anemometry in a fluid mechanics course. Unfortunately, an expensive apparatus to generate a controlled low turbulence jet is required. The use of hydrodynamic tunnel in order to initiate hot-wire anemometry in undergraduate course is appropriately utilized in ref. [6]. Utilizing a hydrodynamic tunnel good calibration results can be found easily if several delicate procedures have rightly executed.

All hot-film measurements have been carried out utilizing the hydrodynamic tunnel. The hot-film probe has been positioned downstream the sphere (at Y = 5 D) and transversally moved (X direction) in order to obtain the relative turbulence level, depicted in fig.(6).

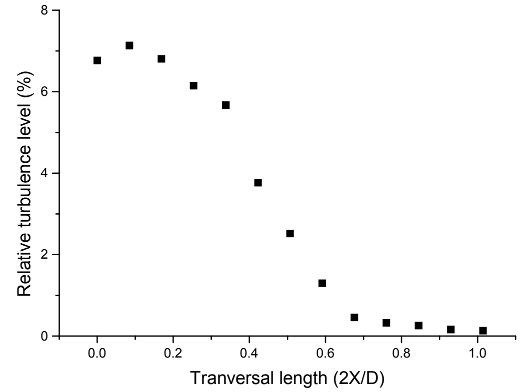

FIGURE. 6
TURBULENCE RELATIVE LEVEL IN THE SPHERE WAKE.

In the hydrodynamic tunnel visualized images in close view can be obtained. An example of these images can be observed in Fig.(7).

CONCLUSIONS

In this paper a wake configurations observed behind a sphere falling in quiet water at terminal velocity has been proposed to an experimental class in a fluid mechanics undergraduate course. Two proposed devices – The hydrodynamic tunnel and the water Plexiglas tank – allow a careful observation of various wake-shapes images and quantitative measurements with their corresponding Reynolds number.

Experiments realized in water medium has certain advantages as a fluid medium for incompressible turbulence studies compared with air. Lower velocities may be utilized with the same Reynolds number since the kinematic viscosity (ν) of water is only one-sixteen that the air implicating in the use of lower frequency velocity sensors.

A water tank is a very cheap apparatus easy to make and to operate, permitting to obtain relative good results. Several aerodynamic concepts are possible to corroborate in this device.

Those experiments have been developed in a fluid mechanics laboratory class for, in average, six students each time. The less number of students permits a very close accomplishment, eliminating several students' doubts. A more high number of students can be an additional difficulty to the instructor, mainly in the hydrodynamic tunnel operation.

Massively separated flows as observed in a sphere wake or in many other bluff-bodies, found in several engineering applications, has been shown to be an ideal mechanism to introduce good laboratory procedures as well as procedures that have wide use in technological industries and research laboratories.

The different measurements done by student's action in the hydrodynamic tunnel and in the water tank have awaked great motivation in undergraduate students of fluid mechanics.

Other attractive point of this laboratory class is related to the use of sophisticated pieces of instrumentation. In fact, the use of "real instrumentation" like digital processing, constant temperature anemometer and the hydrodynamic tunnel in order to obtain fluid flow velocity, turbulence and other important parameters in a laboratory class, in opposition to demonstration-only experiments, highly increases the student's motivation to grasp a difficult and complex subject. In this way, the use of HWA as a teaching tool has proven to be very important to attain the goals set by the fluid mechanics instructors in engineering undergraduate studies.

ACKNOWLEDGMENT

This work has been possible due to of the FAPESP grants. The authors are grateful too to Fundunesp and Proex/Unesp. The authors wish to thank too Dr. João Batista Aparecido for comments on the manuscript.

DATA TRANSFER PROTOCOL FOR DISTRIBUTED INFORMATION ACQUISITION FOR USE IN PHYSICAL EXPERIMENTS

Alexei Korolkov[1], Alexei Moschevikin[2], Alexei Soloviev[3]

Abstract *— Data Transfer Protocol for Distributed Information Acquisition (DTP/DIA) was designed and proposed to IETF to be an experimental standard (TCP port 3489 have already assigned to DTP/DIA by IANA). DTP/DIA is based on TCP/IP stack and supports such devices as sources of physical information (sensors), transit transmitters and receivers, connected with data base engines. All these devices are usually constructed with embedded microcontrollers (Atmel, Microchips, Intel) with reduced cost. The main features of DTP/DIA are: simple realization, reliability, ability to resolve various sources of information, support up to 2^{24} unique devices. Due to implementation of TCP procedures and utilization of world communication channels sources and receivers may be far distanced. Practical realization of DTP/DIA was introduced in net of online air temperature sensors in North-west Russia (http://thermo.karelia.ru/eng/). Also there is an ability to construct measurement and data acquisition nets for any physical quantity including mixed nets (for example for pressure, humidity and temperature sensors).*

Index Terms — data transfer protocol, distributed information acquisition, embedded microcontrollers, online air temperature, sensor net.

INTRODUCTION

The Data Transfer Protocol for Distributed Information Acquisition (DTP/DIA) was developed for application in distributed information measurement systems (IMS). DTP/DIA provides the functionality of the presentation and application layers of the OSI Reference Model for the specified purposes.

IMS stands for a bundle of software and hardware which performs acquisition, processing, storing, and presentation of measured data. The systems with control function are out of scope. The simplest IMS consists of measuring device, connected to computer by means of some instrument interface (such as IEEE 488 (GPIB) or EIA/RS 232). Typical measuring device contains a sensor and a microcontroller, which performs initial data acquisition and processing. In such a system the majority of IMS functions are given to computer.

More complicated systems can be developed on the basis of CAMAC or VXI. But projects with large amount of investigated objects at far distances from each other require to install distributed IMS. Some nodes of distributed IMS should perform data transmission to nodes which process and store data. Sometimes this communication can be done by measuring device itself if it is rather sophisticated, or this function may be performed by a computer. That is we deal with two kinds of data channels: local (1) and network (2) (Fig.1).

In description of IMS we use the term "data source" for the object, which transmits measured data, and "data collector" - for the node which receives measured data. If the node performs both reception and retransmission, this type of nodes will be named "retranslator". Obviously, in this terminology measuring devices are "data sources", but a single computer could be either "end-point data collector" or "retranslator".

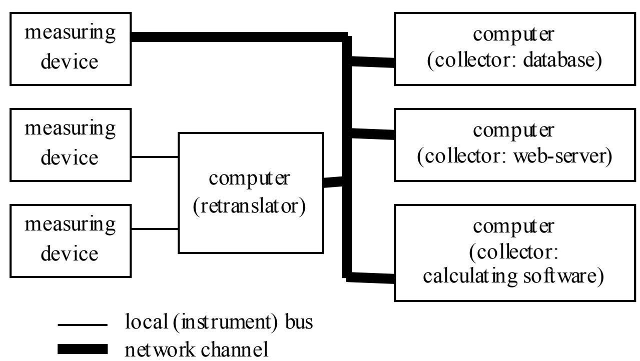

FIGURE. 1
A TYPICAL STRUCTURE OF DISTRIBUTED IMS.

In most cases the nodes of distributed IMS are considered to be the components of the open systems. So OSI Reference Model can be applied to their communication channels. The upper layers of such systems are poorly standardized due to the wide range of IMS's applications. The most of existing standards are vendor-specific. That's

The research described in this publication was made possible in part by Award No. PZ-013-02 of the U.S. Civilian Research & Development Foundation for the Independent States of the Former Soviet Union (CRDF) and of Ministry of Education of Russian Federation.

why it's necessary to introduce a simple protocol, suitable for both kinds of data channel. DTP/DIA matches these requirements.

DTP/DIA was implemented in both embedded firmware (for Atmel microcontrollers) and personal computer software (Distributed Information Acquisition software – DIA).

MAIN FEATURES OF THE DTP/DIA

The protocol describes data transmission in small stand-alone packets. This feature allows using DTP/DIA over both streamed (connection-oriented) and message-oriented channels. DTP/DIA packet consists of three logical blocks: *Header*, *Measured Data* and *Special Data*. *Header* and *Measured Data* are required. They have a fixed size. *Special Data* block is recommended and its size is variable. The maximal size of DTP/DIA packet is 60 bytes. A simple measuring device must produce packets, contained at least *Header* and one of the forms of *Measured Data* block. More sophisticated device should include *Special Data* block as well.

DTP/DIA provides few data presentation forms. Each form corresponds to a specific packet type. Some of the forms help to avoid the implementation of floating point arithmetic in device firmware.

DTP/DIA allows transmission of measured data accompanied with information about measurement error and its unit measure.

In distributed IMS it is very important to distinguish measuring devices from each other at the application layer. So the protocol includes identification mechanism. This feature helps to transmit data from several data sources over a single communication channel. For example, one can use a device with several sensors (such device is represented as multiple data sources). To distinguish data from various data sources DTP/DIA packet contains Data Source Identifier. To introduce a bit of structurization in distributed IMS the Identifier was divided into two parts. They correspond to high and low levels of 2-level hierarchy. Developer of IMS may use the first part to specify the group of units in distributed IMS and the second part to appoint a device number in this group. The protocol supports up to 16 millions (2^{24}) data sources.

Another important part of the DTP/DIA identification mechanism is an optional feature called the *Data Source Identification Procedure,* which helps sharing a single transport layer connection for data transmission from several data sources. This feature is not supposed to be applied to connectionless (message-oriented) channels. So data source can distinguish every collector by a certain transport layer connection. This mechanism consists of two events: "Offer To Identify" and "Device Request". They represent a some kind of handshaking. Also *Data Source Identification Procedure* may be applied for assigning identifiers.

We suppose to apply DTP/DIA for both network and local channels. Few types of local channels don't provide reliable data delivery. To avoid unreliability of local interfaces DTP/DIA has the following primitive features: detection of packet start (packet leading sequence), check sum and time stamp.

DTP/DIA provides neither authentication mechanism, nor security issues. To produce security based applications developer of IMS should provide authentication and data protection on the transport layer (by means of SSL [2] or TLS [1]).

DIA SOFTWARE

Distributed Information Acquisition Software fully implements the described protocol. It was developed and tested on several platforms: Windows 95/98/Me, Windows NT/2000/XP and Linux. The program was also tested on FreeBSD in Linux-emulator. Linux version can be linked statically and placed with the Linux kernel on a floppy disk. So it can be used in diskless low-performance systems (floppy required only). The main part of the program is provided with open sources under the terms of the GNU Lesser General Public License.

The program deals with objects of two kinds: *Device* and *Channel*. *Device* objects represent a particular data source and store current measuring information (date of measurement, measurement result, accuracy, units etc). *Channel* objects hides the method of data receiving and transmitting from other parts of the program. Such object implements input/output procedures for a specific communication resource (serial port, TCP-socket, UDP-socket, file, database, etc). Although it is not limited by the protocol, the current release of the DIA software doesn't support bidirectional *Channel* objects, i.e. any *Channel* object must either transmit data or receive it. Each *Device* object may be connected with few transmitting or receiving channels. Transmitting channels implements the "retranslator" function in the terms of DTP/DIA. Moreover the data storing function is the transmitting function as well. That is when we suppose to store measuring information in a file or database we assign a certain transmitting channel to corresponding object, which "transmits" data to file or database.

The open-source interface of objects interconnection and the modular structure of the program allow developing a module for any communication resource. The program can use new modules without recompiling. At the moment we have implemented the following communication modules:

- RS232 module performs communication via serial line.
- FILE module allows receiving of data from file. It is supposed that new data arrives when file modification time is changed. This module can be flexibly configured to support different file formats.
- MYSQL module provides the opportunity to store data in MySql database.

- TCP/UDP module supports receiving and transmitting of data over Internet/Intranet channels ([5], [6]). When the program transmits data by means of this module it acts as retranslator in the terms of DTP/DIA. This module can be configured to use SOCKS5 proxy [3].
- SSL module performs secure receiving and transmitting of measuring information. It provides some kind of authentication. At the stage of SSL handshaking both communicating sides should provide certificates, which are signed by trusted certification authority. Otherwise the connection establishment won't be authorized and SSL handshaking will fail.
- CTRL module implements some control interface, which allows creation and removing of both kinds of objects in the run-time. This feature provides the opportunity to configure the distributed IMS dynamically. By means of this module the operator may watch the state of all the objects in the running program.
- SMTP module implements a simple SMTP client according to [4]. It is supposed to inform the operator about long network time-outs. Because of various SMTP gates this information may be delivered to SMS, pager or ICQ.

DTP/DIA IN MICROCONTROLLER FIRMWARE

The realization of DTP/DIA in microcontroller built-in software is rather unsophisticated due to simplicity of the protocol. Binary code of packet formation and transmission procedure does not exceed 100 bytes in case of hardware UART in MCU (microcontroller unit).

One of the examples of DTP/DIA implementation is temperature sensor, based on Atmel MCU AT90S2313, which has the following useful features:

- 2K bytes of in-system programmable flash memory;
- 128 bytes of SRAM;
- programmable watchdog timer;
- full duplex UART;
- low power consumption.

Block scheme of device is presented in Fig.2.

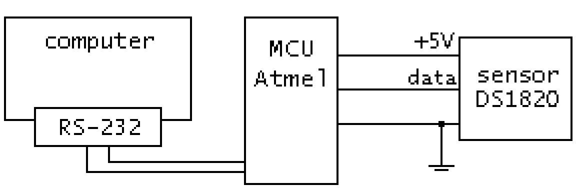

FIGURE. 2
BLOCK SCHEME OF DIGITAL TEMPERATURE SENSOR.

Digital sensor DS1820 (Dallas Semiconductors) is connected to MCU through 1-wire interface in slave mode. MCU puts various commands on data line and sensor replies. The whole cycle of data acquisition includes: sensor reset, temperature registering procedure, another sensor reset, temperature read procedure, processing read data, transmitting the data and sleep period (aimed at power saving). The stage of processing is necessary when digital format of obtained data does not comply with the certain field specification in DTP/DIA. For example, the most common format of DTP/DIA packet assumes the transmitting real physical value multiplied by 10 to escape fractional part (usually, it is sufficient to know value with accuracy of ±0.1).

Lets suppose that we read 19 from scratchpad of sensor (that means temperature of 19°C). Decimal X=19 in binary form is expresses as 00010011. This value should be multiplied by 10 and then be transmitted to computer-collector or retranslator (all calculation must be performed by MCU having no such direct instruction). Multiplication by 10 is appeared to be produced as 8*X+2*X=10*X. Multiplication by 2 and 8 carries out by simple instruction LSL (logical shift left). Once applied, new value in MCU's register is two times greater than previous. Let R0 to be a 8-bit register, then…

command	R0-register (00010011 - initial)	decimal expression in R0-register	action
lsl	00100110	38	*2
lsl	01001100	76	*2
lsl	10011000	152	*2

If the values in the first and third strings are summed the result will be 190.

Each DS1820 has unique 64-bit hardware number. They are partially used in forming Data Source Identifier field in DPT/DIA packets. Due to this feature few sensors may be connected on the 1-wire interface to one MCU. Microcontroller distinguishes various sources, so any distributed network of sensors may be constructed both with use of local and network channels (Fig.1).

ONLINE AIR TEMPERATURE SENSORS NET

On the basis of described protocol the online net of air temperature sensors was created (web version see at http://thermo.karelia.ru/eng/). It covers the territory of Republic of Karelia (North-west Russia). Also one of the sensors is distanced at several thousand kilometers from Petrozavodsk and is situated in Mezhdurechensk (Kemerovsky region). Geographical scheme of Karelian region is presented in Fig.3.

Three letter abbreviations on the map stands for different towns in Karelia. PAA – Paanayarvi, LOU – Louhi, SEG – Segezha, PTZ – Petrozavodsk, SOR – Sortavala. Arrows near the names of towns designate the current rise or fall of air temperature in respect to previous hour value.

All sensors yield data every 5 minutes and transmit them through Internet channels to the collector server situated in Petrozavodsk. Collector, database and web-server software is running on one computer. The main difference between various sensors is the way of data transfer and physical connection of sensors to data transfer devices.

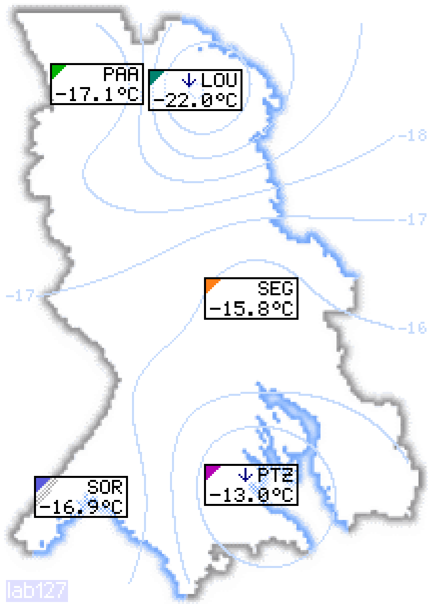

FIGURE. 3
KARELIAN MAP MARKED WITH TEMPERATURE MEASUREMENT POINTS.

Graphs (3-day, 3-week, 3-month and 1-year periods) with time dependence of air temperature are renewed every half hour.

Almost all temperature sensors are connected to network in various ways. LOU sensor is connected to COM port of computer running under Windows NT, SEG – Windows 98. Both are hidden behind firewall. Sortavala's is connected to gate's COM port, which is mapped to certain TCP port (feature of Cisco Systems hardware). All computers except PTZ and Mezhdurechensk (MER) sensors have Internet accessible IP addresses. PTZ and MER have local IP addresses and are translated by NATs (network address translation services). Moreover, PTZ sensor is constructed on not DS1820, but on MAX6577. So data transmission is carried out through FILE channels. To establish more security SSL connection with authentication and certifications was implemented between retranslator and collector computers. PTZ computer runs under Linux, and MER computer runs under FreeBSD.

Collector software stores temperature data from various town in corresponding log files. Web-server software and additional scripts build graphs, banners, and other required for certain web-design objects in HTML-pages.

Due to universality of DTP/DIA the same network channels may be used for transmission of various types of physical quantities. Any packet may include fields for quantity identification, unit measure (for example, °C), confidence interval and accuracy. It is up to collector software to determine each source and physical quantity sent.

ACKNOWLEDGMENT

We'd like to express gratitude to all our colleagues at the department of information measurement systems and physical electronics of Petrozavodsk State University for support in this project.

PROJETO E CONSTRUÇÃO DE UM POLARISCÓPIO MODELO PARA DISSEMINAÇÃO DA TÉCNICA FOTOELÁSTICA EM ENGENHARIA E EM CURSOS BIOMÉDICOS

Prof.Dr.Perrin Smith Neto and Prof.MsC José Luiz Silva Ribeiro

Resumo- O presente trabalho trata do projeto e construção de um polariscópio modelo, para disseminação da técnica fotoelástica, tanto nas engenharias, como nas áreas biomédicas, com informes sobre sua construção e utilização.
Para fins de projeto, foram feitos estudos sobre os conceitos básicos da Fotoelasticidade, com relação aos elementos constituintes de um polariscópio plano-circular de transmissão, com mobilidade de placas para compensações (principalmente Tardy), instrumento fundamental na área, e sobre a utilização destes conceitos na análise de peças / fatias fotoelásticas. Foram ainda realizadas visitas a várias instituições de renome, que trabalham com polariscópios, levantando-se dados sobre seus equipamentos, a utilização dos mesmos, e as necessidades de um polariscópio na prática da Fotoelasticidade.
O projeto final escolhido foi um polariscópio de construção relativamente simples, para execução em oficina mecânica de usinagem convencional, de pequeno a médio porte, com necessidades mínimas de construção e manutenção. Visou-se, mais do que detalhes mecânicos, a popularização do instrumento e, conseqüentemente, da técnica, no entanto sem perder a flexibilidade do instrumento e a qualidade da imagem. Os materiais utilizados, alumínio, plástico, metalon, bem como os detalhes construtivos, são caracteristicamente atuais, produzindo um instrumento leve, funcional, portátil, de baixíssimo custo e ainda atraente. Embora sua usinagem e montagem tenham sido simplificadas, o equipamento pode ser utilizado, segundo a metodologia de uso indicada, sem nada perder na qualidade de suas análises e em suas principais aplicações

Introdução

A proposta de projeto e construção de um polariscópio modelo, juntamente com a fundamentação da fotoelasticidade, surgiu da necessidade de um polariscópio de transmissão, atualizado, de baixo custo, para a análise experimental de tensões no Laboratório de Análise Experimental de Tensões do Instituto Politécnico da Pontifícia Universidade Católica de Minas Gerais. O estudo do polariscópio, foi voltado para o projeto e construção de umpolariscópio modelo com simplicidade de construção, baixo custo de fabricação, baixo custo de manutenção e flexibilidade de utilização. A técnica fotoelástica é de fundamental importância na solução de problemas relativos à obtenção da distribuição real de tensões em peças e equipamentos,com emprego em várias áreas da engenharia, com ênfase na mecânica dossólidos, na engenharia civil, mecânica, mecatrônica e também em bioengenharia, na área biomédica, em vários campos da odontologia emedicina. Um polariscópio de transmissão básico, não produzido no Brasil, tem um custo aproximado de US$ 18.000,00. O custo do equipamento modelo, construído nas oficinas do Instituto Politécnico da PUC Minas situa-se na faixa de US$ 3.000,00. Este custo é perfeitamente acessível às instituições de ensino do país. A sua usinagem e montagem foram simplificadas para facilidade de construção, sem, entretanto, prejudicar a qualidade das análises efetuadas, podendo o equipamento ser utilizado com eficiência, seguindo-se os procedimentos de utilização desenvolvidos. Para projeto, construção e experimentação, foram desenvolvidos estudos para a fundamentação dos conhecimentos da técnica fotoelástica, sintetizados nesta dissertação, como uma referência básica para aplicação no desenvolvimento de pesquisas no Mestrado e na Graduação. Foram realizadas visitas a várias instituições de pesquisa e ensino, que trabalham com polariscópios, levantando-se dados sobre seus equipamentos, a utilização dos mesmos, e as necessidades de um polariscópio na prática da Fotoelasticidade. Voltadas para a utilização desta técnica, em trabalhos relacionados à mecânica e automobilística, muitas aplicações já se encontram em andamento, estando assim o equipamento subsidiando pesquisas em peças bidimensionais e tridimensionais. A divulgação do presente trabalho, deverá incrementar os estudos relativos ao assunto, nas pesquisas científicas dos cursos de Graduação e nos trabalhos de pesquisa do Mestrado, alguns destes, já em franco andamento, bem como possibilitar o intercâmbio de conhecimento entre outros pesquisadores, em outras instituições que queiram se desenvolver ou iniciar seus trabalhos de pesquisa por este fértil campo.

Tipos de Polariscópios

Utilizando-se arranjos entre os elementos óticos anteriormente descritos, podese obter várias possibilidades de montagem e construção de polariscópios, para diversas aplicações. Como, para cada aplicação, pode-se obter melhor performance com este ou aquele tipo de polariscópio, descrever-se-á sobre os modelos de maior aplicabilidade.

Disposição dos Elementos Óticos em um Polariscópio O Polariscópio Plano

O polariscópio plano é o mais simples dos sistemas óticos usados em fotoelasticidade; consiste em dois polarizadores lineares e uma fonte de luz.cruzados, conforme figura 1.

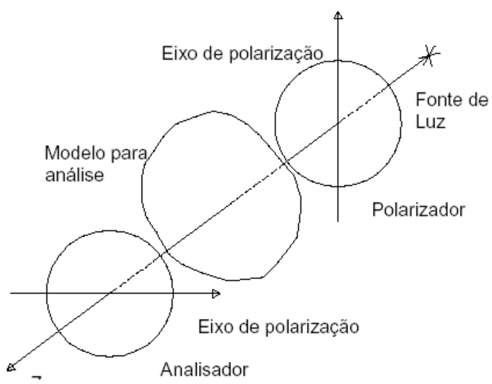

Figura 1- Polariscópio Plano

O linearizador mais próximo da fonte de luz é denominado polarizador e o mais afastado analisador. Neste tipo de polariscópio, se os eixos de polarização são cruzados, nenhuma luz é transmitida através do analisador e esta montagem produz o chamado campo escuro. Em operação, um modelo fotoelástico é posicionado entre os dois elementos e observado através do analisador.

O Polariscópio Circular

O polariscópio circular emprega a luz circularmente polarizada. O equipamentodispõe então, de quatro elementos óticos e uma fonte de luz.

O primeiro elemento a partir da fonte de luz é o polarizador. Ele converte a luz comum em luz plana polarizada. O segundo elemento é uma placa de quarto de onda posicionada em ângulo b = p / 4 em relação ao eixo de polarização.

Esta placa de quarto de onda converte a luz plana polarizada em luz circularmente polarizada. O terceiro elemento, a segunda placa de quarto de onda, é posicionada com o seu eixo rápido paralelo ao eixo lento da primeira. O motivo da presença deste elemento é converter a luz circularmente polarizada em plana polarizada novamente, vibrando no plano vertical. O último elemento é o analisador, com o seu eixo de polarização posicionado na horizontal, com o objetivo de extinguir a luz.

Esta série de elementos óticos constitui a disposição padrão de um polariscópio circular, produzindo um campo escuro. Mais três arranjos destes elementos óticos são possíveis, dependendo tanto do posicionamento dos polarizadores como das placas de quarto de onda. A Tabela 1 descreve estes arranjos:

Tabela 3.1 Quatro disposições de elementos óticos num polariscópio circular.

Arranjo	Placas de ¼de onda	Polarizador e Analisador	Campo
A	Cruzadas	Cruzados	Escuro
B	Cruzadas	Paralelos	Claro
C	Paralelas	Cruzados	Claro
D	Paralelas	Paralelos	Escuro

Tabela 1 Quatro disposições de elementos óticos num polariscópio circular.

Polariscópio de Reflexão

Trata-se de técnica que permite uma visualização global do campo de tensões e deformações a que se submete a peça ou conjunto analisado, não requerendo confecção de modelos, uma vez que a obtenção dos parâmetros se dá diretamente nestas peças, conjuntos ou estruturas, quando estes se encontram submetidos à seus carregamentos reais. O componente ou conjunto a ser analisado necessita ser, primeiramente, limpo, retirando-se qualquer resíduo de tinta, graxa ou sujeira, que possa comprometer a análise. Consiste em aplicar fina camada de tinta reflexiva que, após seca, será recoberta com uma camada de material fotoelástico, utilizando-se de uma cola apropriada, de forma a produzir uma interface entre o corpo a se analisar e a camada, para que, ao se submeter o corpo a um dado carregamento, esta deformação seja transmitida para esta camada fotoelástica. Assim permite-se que as imagens geradas pelos meios óticos, descritos anteriormente, sejam analisadas.

Polariscópio Com Uso de Lentes

Os polariscópios com uso de lentes são empregados somente onde se faz necessário o uso de luz paralela sobre todo o campo de estudo. É também utilizado nas situações onde a luz paralela é importante, incluindo-se aí aplicações onde uma definição bastante precisa de todo o limite do modelo é necessária. Nestas aplicações os reflexos parciais são usados em toda a área fotoelástica, na multiplicação e apuração das franjas. Muitas variações de sistemas de lentes são possíveis.

O Projeto

Para o início do projeto do polariscópio, foram estudados os vários modelos existentes, como polariscópios de luz difusa por transmissão e por reflexão e polariscópios de transmissão com o uso de lentes. Foram feitas visitas técnicas conceituadas instituições como o Departamento de Engenharia Mecânica da Universidade Federal de

Figura 2 Polariscópio de transmissão modelo, construído nas oficinas do Instituto Politécnico da Pontifícia Universidade Católica de Minas Gerais.

Uberlândia; Departamento de Engenharia Mecânica da Pontifícia Universidade Católica do Rio de Janeiro e Centro de Desenvolvimento da Tecnologia Nuclear, CDTN, em Belo Horizonte, Minas Gerais, este último, órgão técnico da Comissão Nacional de Energia Nuclear, CNEN.

Os Componentes do Polariscópio Modelo

A Base do Conjunto

Para a construção da base do polariscópio foi utilizado o perfil retangular em aço ABNT 1020, de dimensões 30 x 50 mm, com espessura de parede de 1,26 mm, cortado e soldado de forma a prover uma base retangular de 400 x 1400 mm. Esta base é diretamente apoiada em mesa ou bancada, tendo como função suportar o conjunto dos sistemas óticos, o sistema de carga, a fonte de luz e o pino de travamento e referência, para a fixação dos dispositivos de registro das imagens geradas. Ao longo da maior dimensão da base, foram usinados furos com diâmetro de 5 mm, para a fixação dos citados conjuntos e do sistema de carga, permitindo ajustes no sentido longitudinal ao eixo do instrumento, possibilitando a inclusão ou retirada de acessórios e fornecendo variadas configurações em função dos objetivos esperados.

.A Fonte de Luz

Para abrigar a fonte de luz do sistema, foi projetada uma caixa fechada, pintada internamente em branco liso, contendo apenas uma saída para o feixe de luz, por meio da fixação de uma chapa de alumínio vazada com a forma circular, onde se fixou externamente uma placa de acrílico branco, denominada placa difusora. Foi também incluída uma placa de acrílico de cor vermelha, para possibilitar o estudo de franjas isocromáticas mais definidas, com o uso de filtro monocromático, conforme descrito anteriormente. Na Fig. 3 tem-se uma vista da fonte de luz montada sobre a base do conjunto sem a placa difusora. Na parte posterior da fonte, foi acrescentada uma veneziana, para permitir a ventilação, evitando o superaquecimento das lâmpadas e das placas difusoras de acrílico. No fundo da fonte de luz foi incluído um ventilador para forçar o fluxo de ar e provocar uma troca de calor eficiente. Vários tipos de lâmpadas foram pesquisados.

Figura 3. Detalhe da fonte de luz e sua montagem sobre as guias de fixação da base do conjunto, observando-se, na parte superior, a veneziana de ventilação.

Em princípio procurou-se no mercado a lâmpada de vapor de sódio de baixa pressão, uma vez que Neto (1980) cita que, este tipo de lâmpada, produz uma luz monocromática, o que poderia ser uma das opções para a fonte. Entretanto, esta lâmpada não é encontrada no Brasil, segundo informações de fornecedores. Também foram estudadas as lâmpadas fluorescentes do tipo Branca Natural, com potência de 20 W, neste caso, ao contrário da lâmpada anteriormente citada, possui excelente espectro de freqüência luminosa, permitindo ótima reprodução de cores. Como fornece somente 650 lúmens de fluxo luminoso e necessita de reatores e outros acessórios, foi inicialmente descartado o seu uso. Outras lâmpadas foram estudadas, tipo incandescentes e fluorescentes compactas, sem melhores resultados, tendo sido escolhidas, então, as lâmpadas de filamento de tungstênio de 300 W, halógenas palito, tipo HA 300 da Philips, podendo ser utilizada outra similar, permitindo assim uma fonte de luz branca e de alta intensidade, emitindo um fluxo luminoso de 5100 lúmens cada, não sendo necessário o uso de reatores ou outros acessórios alem dos suportes das lâmpadas e fiação.

Os Conjuntos Óticos

Os principais componentes do polariscópio são, seguramente, os conjuntos óticos, pois as placas polarizadoras e de quarto de onda são a essência de seu funcionamento. Como um dos maiores fabricantes de sistemas de análise experimental de tensões, o grupo norte-americano Measurements Group, fabricante dos produtos Vishay, foi escolhido para o fornecimento destes componentes não fabricados no Brasil. Foram escolhidas placas polarizadoras lineares nas dimensões de 304,8 x 304,8 mm (12 x 12 pol.), com espessura de 0,762 mm (0,03 pol.), código do fabricante nº 100 -011991, e placas de quarto de onda, código nº 100 -011985, nas mesmas dimensões, sendo todas posteriormente cortadas na forma de disco, com o diâmetro de 300 mm.

Figura 4. Anéis graduados, pré-montados com os anéis retentores das placas de onda e polarizadores.

Para alojar estas placas nos conjuntos óticos, foram construídos quatro anéis graduados em aço inoxidável, com diâmetro interno de 300 mm, contendo marcações de 360 graus (resolução = 1 grau), onde as placas ficam protegidas externamente por meio de lâminas de vidro de 2 mm de espessura, com o mesmo diâmetro das placas óticas, sendo fixadas por meio de um anel retentor, conforme se observa na Fig. 4.Os anéis graduados foram montados em placas de alumínio com a espessura de 4 mm, contendo guias de referência angular de cada lado do conjunto, permitindo a movimentação dos mesmos para a leitura dos ângulos. Cada conjunto ótico é composto de uma placa polarizadora e uma placa de quarto de onda, cada uma com giro livre em relação à outra. Para permitir sustentação e perpendicularismo destes conjuntos em relação à base do equipamento, estas placas de alumínio foram parafusadas em uma estrutura retangular construída em perfis de alumínio e esta, parafusadas à base.

O Sistema de Carga

Nos estudos fotoelásticos, os modelos a serem analisados são submetidos a variados tipos de esforços, para que se analise o seu comportamento em função da aplicação destas cargas na estrutura real ou em desenvolvimento. Para tal, faz-se necessário a utilização de vários tipos de sistemas de carga, contendo diversos tipos de acessórios, entre eles células de carga, que permitem manter o modelo submetido a determinados valores de tensão, enquanto são feitas as leituras de ordens de franja. Na Fig. 5 tem-se a configuração para ensaios em barras submetidas à flexão pura.

Figura 5. Acessórios do sistema de carga, com a configuração para ensaiosde flexão pura

O sistema proposto permite efetuar ensaios de flexão pura, com a utilização de alguns acessórios e ainda de tração ou compressão. Observa-se na montagem a célula de carga e os dispositivos de fixação dos modelos.

Acessórios

Para fixação de uma câmera de vídeo CCD e de outras câmeras (fotográficas ou digitais) utilizadas para a captação das imagens geradas no polariscópio, foi disponibilizada uma haste regulável (nos sentidos longitudinal, transversal e vertical), com as dimensões idênticas às de outros equipamentos disponíveis no laboratório de análise experimental de tensões, permitindo ampla intercambiabilidade destes equipamentos e dispositivos.

Figura 6. Detalhe da montagem do sistema de cargas, com o suporte superior com rolamento. Oficinas da PUC – MG.

Figura 8.Montagem de uma câmera CCD, com seus dispositivos eacessórios, na haste regulável do polariscópio

Discussão e Conclusão

Embora cada componente do polariscópio tenha sido desenhado em AutoCAD 2000 e discutido com a equipe de construção durante o seu projeto, ao longo do processo de construção, algumas alterações tornaram-se necessárias, em função de variados fatores. Alguns componentes em alumínio, por exemplo, foram alterados devido ao fato de que, embora tivesse sido tomado o cuidado de escolher as dimensões dos componentes em catálogos de fabricantes durante a fase inicial, no momento da aquisição, estes não eram facilmente encontrados ou então os fornecedores somente se dispunham a vender quantidades muito elevadas. Para atender aos padrões de comercialização de perfis e chapas no mercado local, foram feitas algumas alterações dimensionais, que não comprometeram a proposta inicial e, em alguns casos, até facilitaram, pois permitiram aquisições de componentes em tamanhos próximos aos da usinagem final, agilizando os trabalhos da oficina.

Embora a maioria dos componentes usados não necessitassem de usinagens complexas, a construção dos anéis graduados tomou, da equipe de idealização e construção, tempo e seguidas discussões. Previsto inicialmente para ser construído em alumínio, logo de início foi alterado para aço inoxidável, para melhor resistir aos esforços de torneamento, sem empenamentos. Também foi este componente que necessitou de mais estudos, junto às empresas que fazem gravação de letras e números, uma vez que normalmente trabalham com uso de fotolito para corrosão por ácido. Ao final, optou-se por termoimpressão, com uso de um padrão em papel vegetal especial, impresso em copiadora de alta resolução, com base em desenho em AutoCAD 2000. Para fixação da tinta nas chapas e demais componentes de alumínio, foram utilizadas tintas e bases especiais para tal, permitindo um acabamento de ótima qualidade. Os componentes mais caros foram as placas polarizadoras lineares nas dimensões de 304,8 x 304,8 mm (12 x 12 pol.), com espessura de 0,762 mm
(0,03 pol.) e as placas de quarto de onda nas mesmas dimensões, em torno de US$ 600,00 (incluindo-se impostos de importação e despesas de transporte). Esta escolha, de tamanho das placas polarizadoras e das placas de quarto de onda, permitiu a obtenção de um campo de ótimo tamanho, possibilitando a
visualização completa de conjuntos mecânicos, que possam ocupar até os 290,00 mm de diâmetro. Vigas com entalhes e componentes mecânicos, por exemplo. Para trabalhos onde é necessária uma ampliação da imagem, ou o estudo de detalhes de uma dada parte de uma peça ou fatia (no caso da técnica do congelamento), pode-se acoplar lentes ao conjunto, ajustando as placas em variadas posições ao longo da base de apoio. Também, podem ser utilizadas câmaras fotográficas reflex, digitais com zoom, câmaras de vídeo e em especial as câmaras CCD, que produzem imagens ampliadas e permitem análises detalhadas de pontos mais críticos do modelo. Os demais materiais utilizados na construção custaram em torno de US$ 2.000,00. A mão de

obra da oficina foi estimada em 100 horas de tornearia e outras 100 em fresadora, plaina e furadeira radial, além de 80 horas de artífices mecânicos e pintura. Levando-se em consideração o custo de aquisição de um equipamento novo, importado, e ainda que este equipamento possua inúmeros recursos e acessórios, será de aquisição muito difícil para uma universidade que tem tantas prioridades de investimento, necessitando de linhas especiais de financiamento junto aos órgãos de incentivo à pesquisa ou empresas que trabalhem ou venham a trabalhar em parceria com a instituição. Só para se ter uma noção de valores, o polariscópio do Centro de Desenvolvimento da Tecnologia Nuclear, CDTN, recentemente adquirido por aquela instituição e, ao qual, alunos e professores tiveram acesso para seus estudos, por meio de convênio, foi avaliado por seus técnicos em torno de US$ 45.000,00. Sem os citados acessórios seu preço de custo diminui para aproximadamente US$ 18.000,00, portanto, um polariscópio básico, de custo em torno de US$ 3.000,00, torna-se uma alternativa simples e extremamente econômica para a realidade brasileira. Ainda durante a construção, diversos cuidados foram tomados para o alinhamento do sistema de fixação dos conjuntos óticos sobre a base. Foram executados furos contíguos, ao longo da base do conjunto, com distanciamento de 50 mm, para permitir que o sistema de cargas e as placas pudessem ser movimentados longitudinalmente, sem que se comprometesse o paralelismo do conjunto, podendo ser, por exemplo, utilizado externamente a fornos / estufas, realizando trabalhos com peças aquecidas. Na pesquisa de tipos de lâmpadas foram estudadas várias possibilidades, sendo escolhida a de filamento de tungstênio de 300 W, halógena tipo palito, permitindo uma fonte de luz branca e de alta intensidade, que emite um fluxo luminoso de 5100 lúmens, não sendo necessário o uso de reatores ou outros acessórios. Para possibilitar análises em materiais modelados com a técnica de congelamento, para fotoelasticidade tridimensional, foram instaladas duas destas lâmpadas, permitindo um feixe de luz mais intenso. Embora tenha sido instalado um ventilador, para evitar o excessivo aquecimento da fonte de luz e, principalmente das placas difusoras branca e vermelha, após alguns minutos de utilização, estas placas de acrílico se dilatavam, dificultando a troca de uma pela outra, quando aquecidas. Uma pequena diminuição na largura das citadas placas resolveu este problema. Com relação aos filtros vermelhos utilizados, tanto na fonte quanto na câmara fotográfica, ainda que os mesmos possam auxiliar a leitura de ordens de franja, não produzem um efeito monocromático perfeito. Foi utilizado, também, um filtro de cor amarela na câmara fotográfica, sem resultados positivos na avaliação de franjas, uma vez que várias tonalidades de cor foram observadas com seu uso, sem uma definição tão boa quanto a obtida com o filtro vermelho. Os padrões de franja apresentados nos modelos carregados, são ricos em informações, podendo sugerir os pontos onde se pode obter atenuações de tensões apresentadas, com pequenas alterações na geometria da peça e outras medidas, permitindo, em alguns casos, a diminuição de espessura ou quantidade de material empregado, reduzindo assim custos em toda a escala produtiva. Este é um dos mais importantes usos do polariscópio, podendo fornecer aplicações didáticas para várias disciplinas, tanto de cursos de engenharia (mecânica, mecatrônica, civil, etc.) como Resistência dos Materiais, Elementos de Máquinas, etc., como para odontologia (próteses, implantes dentários, brocas e ferramental), entre outras, onde se estudem os efeitos de tensões. O fato do polariscópio não possuir giro sincronizado das placas polarizadoras e de quarto de onda diminui a produtividade dos trabalhos de análise. Entretanto, tal fato não diminui a qualidade das medições efetuadas e, à medida em que o usuário se familiariza com seu uso, adquire uma prática que acelera a leitura necessária. A utilização de marcações prévias sobre os anéis graduados, com números impressos com rotuladores, também é outro fator de agilização e confiabilidade de que os ângulos de rotação estão mantendo as placas em sincronia e que o mesmo se mantém plano ou circular, em função do que se pretende avaliar. Quando se utilizam dois operadores, um girando as placas e o outro observando a imagem, as análises são otimizadas, principalmente quando se utiliza o método de leitura ponto a ponto, que exige a mudança de configuração plana e circular a cada leitura. Na utilização prática do polariscópio, observou-se que estas mudanças são normalmente feitas em incrementos angulares de 5º em 5º ou 10º em 10º, para que se encontre o ponto correto de leitura. O uso de papéis adesivados coloridos, tipo "Post-it", para fixar a referência do zero relativo é outra alternativa que foi utilizada com ótimos resultados, permitindo a leitura ponto a ponto nas marcações efetuadas no modelo. Em suma, com alguns recursos de marcação e prática na utilização, pode-se perfeitamente realizar análises fotoelásticas eficientes, sem a obrigatoriedade de mecanismos de sincronização. O uso de imagens dos modelos tensionados pode, também, ser obtida por fotografias, em especial quando se quer analisar as direções das tensões principais, quando pode-se observar toda a peça ou fatia completa. Após fotografarem-se o modelo com as franjas isoclínicas, pode-se, opcionalmente,
digitalizá-las para os estudos que se pretende fazer. Pode-se ainda transcrevêlas em uma folha de papel contendo o desenho do modelo e, a partir delas, traçar as curvas isostáticas. No caso das franjas isocromáticas pode-se estimar os valores das diferenças de tensão principal por interpolação. Dentre os materiais utilizados na construção do polariscópio destacam-se, em primeiro lugar, o uso intenso do alumínio, permitindo que o mesmo ficasse bastante leve, sem perder a

rigidez necessária para manter as formas originais, seja durante seu uso ou por pequenos esforços que possa sofrer. Também foi utilizado o nylon, na construção dos anéis internos, cuja finalidade é permitir um giro suave dos anéis graduados e prender as placas óticas entre dois discos de vidro de espessura de *2 mm* para cada uma delas. O uso de acrílico leitoso para as placas difusoras, nas cores branco e vermelho, apresentaram, também, resultados muito bons, permitindo a geração de um feixe de luz difusa sobre todo o campo visual. Com o emprego destes materiais, o equipamento ficou leve, compacto, portátil e assim pode ser facilmente transportado em função dos trabalhos que serão realizados com ele. Embora simples, trata-se de um polariscópio completo, tratando-se portanto de um equipamento atual eútil para a pesquisa e docência na Universidade. Na fase de projeto, foi prevista a possibilidade de se efetuarem algumas melhorias que incrementassem o uso do polariscópio. Uma opção, comumente encontrada em polariscópios mais sofisticados, refere à inclusão de mecanismos que efetuem o giro sincronizado das placas óticas. Para tal, modificação faz-se necessária a mudança da espessura dos anéis internos (que fixam as placas óticas nos anéis graduados externos), passando os mesmos a servir como polias, e ainda a instalação de eixos longitudinalmente ao equipamento, contendo polias menores para afixação de cintas, feitas com finos cabos de aço, permitindo o citado giro sincronizado. Para tal, é preciso ainda realizar a remodelação da estrutura de fixação das placas óticas, com aumento do distanciamento entre elas, para conter tais anéis internos. Uma segunda opção, caso se obtenha nova fonte de recursos, é a possibilidade de instalação de uma ou mais fontes monocromáticas. Neste caso, geralmente necessita-se desmontar a fonte difusa e montar umapequena fonte monocromática, com reatores acoplados ou em separado (no caso de fontes realmente monocromáticas). Tratando-se somente do uso de lâmpadas com melhor definição monocromática, as mesmas podem ser adaptadas à fonte existente, tal se repetindo com o uso de lâmpadas incandescentes ou fluorescentes comuns.

Abstract

Studies were performed on the basic concepts of Photoelasticity, regarding the constitutive parts of a transmission plane-circular polariscope, with mobility of the lenses for compensations (mainly Tardy), which is a fundamental tool for the technique, and on the use of these concepts in the analysis of photoelastic parts/slices. Several wellknown institutions, which work with polariscopes, were also visited to obtain information about their equipment, its use, an the need of a polariscope in the practice of photoelasticity.

The chosen final project is a polariscope with a relatively simple construction, to be executed in a small to medium large machining workshop, with minimal construction and maintenance needs. Rather than detailing the mechanisms, the project aimed widespreading the use of the device, and therefore of the technique, without loos of device flexibility or image quality. The materials used -aluminum, plastic, steel profiles- as well as the constructive details are characteristic of up-to-date techniques, producing a device which is light, effective, portable, of very low cost and also attractive. Although its machining, construction and assemblage have been simplified, the equipment can be used, following the indicated methodology, without any lose in the quality of the analysis or in its main applications

DEVELOPMENT OF A SOFTWARE TO BIDIMENSIONAL STRESS ANALYSIS USING PHOTOELASTIC FRINGES

Prof.Dr.Perrin Smith Neto and Guilherme Cremasco Coelho
Pontifícia Universidade Católica de Minas Gerais- Brazil

Abstract- The work has as objective the development of a software of bidimensional stress analysis, capable to process and to analyze images of patterns of photoelastic fringes, obtained of plane polariscops in an automatic way, using a minimum amount of information supplied by the operator. The processing includes the obtaining of the difference between the maximum and minimun normal stress, maximum shear stress ;directions of the maximum normal stresses,isocromatics fringes and isoclinics.This software will allow studies of stress distribution in bodies of complex geometries submitted to several loading and to verify for instance, areas of high stress gradient. The method presented satisfactory results in photoelastic images generated by simulation, however it was not shown satisfactory in treatment of real experimental images. That is probably due to the fact that the methods of phase shifting, thoroughly published in the literature, are based on source of monochrome light, while the equipments used in the measurements used white light, in other words several wavelengths. In the development of phase shifting methods for white light - same that the camera is monochrome - the spectrum of the luminous source, and the answer should be known from the camera ccd to the luminous excitements of different spectra. . Concerning the analysis of monochrome images (that were generated by simulation), the processing presented satisfactory results, as described in the literature.

Introduction

Photoelasticity is a whole field technique that allows one to obtain principal stress directions and principal stress differences in the model. Photoelastic fringe interpretation, in the classical approach is made manually in a punctual form. Modern techniques that uses digital image processing for automatic fringe counting are based in some phase shifting methods.

Many authors proposed the use of more than one wavelength to produce a phase shift in photoelastic patterns. The RGB photoelasticity uses this principle, acquiring the image using a RGB video camera and then separating the red, green and blue images.

Others suggested the half fringe photoelasticity, where only one fringe in permitted in isochromatic pattern. Using this approach, one can obtain isochromatic parameters easily, but with less resolution.

Recent approaches are based in load stepping, where one increases (or decreases) the system of loads acting in the model, making the phase shifting. This approach is not so generic, because in tree-dimensional photoelasticity, one cannot change the loads acting on the slices.

Finally, one can change the photoelastic phase modifying some polariscope arrangements, such as quarter wave plate positions or analyzer positions. This approach seems to be the most simple, because has not restrictions in static applications and does not require RGB cameras or different light filters, although the phase-processing may not be the most simple.

In this work one uses the four image phase shifting method proposed by N. Plouzennec and others, because of the fact that the experimental arrangement is simple, using only a plane polariscope and image recording devices.

Phase shifting

The light emerging from a plane polariscope has the intensity given by

$$I = \frac{I_0}{2}\left[1 + \cos(2\beta - 2\alpha)\cos(2\alpha) - \sin(2\alpha)\sin(2\beta - 2\alpha)\cos(2\pi N)\right] \quad (1)$$

where α is the direction of principal stresses, β is angle between analyzer and polarizer, N is the fringe order and I_0 is the image contrast.

To obtain photoelastic parameters α and N from a plane polariscope, one must introduce a phase shifting. Using four phase shifts, one obtain four different expressions from equation 1, so that this system can be solved for the wrapped (discontinuous) parameters.

The first image is collected when β is taken equal to zero and the polarizer axis is placed at +45º from the reference axis. The equation 1 then turns:

$$I_1 = \frac{I_0}{2}\left[1 - \cos^2(2\alpha)\sin^2(\pi N)\right] \quad (2)$$

Now placing the polarizer axis parallel to the reference axis and making the angle β equal to +45º, 0º and 90º, equation 1 turns, respectively:

$$I_2 = I_0\left[0.5 + \sin(2\alpha)\cos(2\alpha)\sin^2(\pi N)\right] \quad (3)$$

$$I_3 = I_0\left[1 - \sin^2(2\alpha)\sin^2(\pi N)\right] \quad (4)$$

$$I_4 = I_0 \sin^2(2\alpha)\sin^2(\pi N) \quad (5)$$

Parameters determination

The solution of the system of equations 2 trough 5 is:

$$\tan(2\alpha) = \frac{2I_4}{2I_2 - I_3 - I_4} \qquad (6)$$

$$\cos(2\pi N) = \frac{2I_1 + 2I_3 - 3I_0}{I_3 + I_4} \qquad (7)$$

If one take the atan of expression 6, will obtain a discontinuous (wrapped) phase. This happens because atan function has image between -π/2 and + π/2. So, one must do the phase unwrapping. Many researchers have been working in phase unwrapping algorithms, mainly in radar SAR processing. The most simple method is based in the detection of discontinuities and add + π/2 or -π/2 in these points.

Another widely used method in noisy data is the unweighted least squares method, based in the minimization of the total phase discontinuities. Treating this problem through variational analysis, one reaches a partial differential equation problem, the solution of the poisson equation. In rectangular regions the homogeneous poisson problem has a fast explicit solution based in discrete cosine transforms.

Another method, more simple then the least squares approach, is based in the detection of discontinuities of the phase derivatives. When these discontinuous points are detected, in these points one make an interpolation from it's neighborhood. Then these phase derivatives are integrated again. This algorithm was used for this work.

It is important to note that equation 6 is not defined when $2I_2 - I_3 - I_4$ is equal to zero. In some cases, there are regions where it happens, for example, when the isochromatic fringes are too thick, and the term $\sin^2(\pi N)$ is equal to zero not just in the center of the fringe, but in a region around the its center. So, it is important to use image processing routines to make interpolation or to blurr these regions.

To obtain the correct fringe number, one must unwrap from the acos of equation 7. This task is more complicated, since the discontinuous points in this case are not so apparent, the kind of discontinuity is different from those of atan function. To illustrate this problem, in figure 1 one can see an example of a continuous phase φ, and the wrapped from atan(tan(φ)) and from acos(cos(φ)). The algorithm to treat the acos discontinuous phase is based in the detection of places where the derivatives change the sign suddenly.

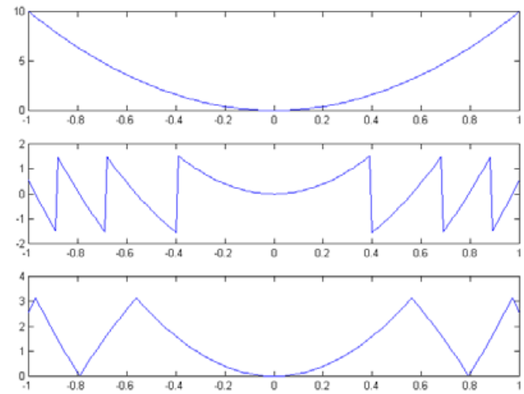

Figure 1. Different kinds of discontinuity. a) An example of continuous phase φ. b) The wrapped phase from atan(tan(φ)). c) The wrapped phase from acos(cos(φ)).

Application

A software were developed for photoelastic analysis using the methods described in this work. Some image processing routines were implemented, such as filters and region of interest processing. Also were implemented phase filters, specially designed for discontinuous data, and a masking routine, to eliminate regions of where the phase is not defined, based in harmonic methods.

The model is a disc under compression. The disc thickness is 5mm, the radius is 60mm, the applied load is 355 N, and the photoelastic constant is 13 KN/m. The images used in this application are shown in figure 2. The rectangular area marked in the images is defining the region used for the processing. The filtered wrapped isoclinic angle is shown in figure 3, and the unwrapped can be viewed in figure 4. In figure 5 one can see the wrapped fringe order, and in figure 6 the unwrapped fringe order.

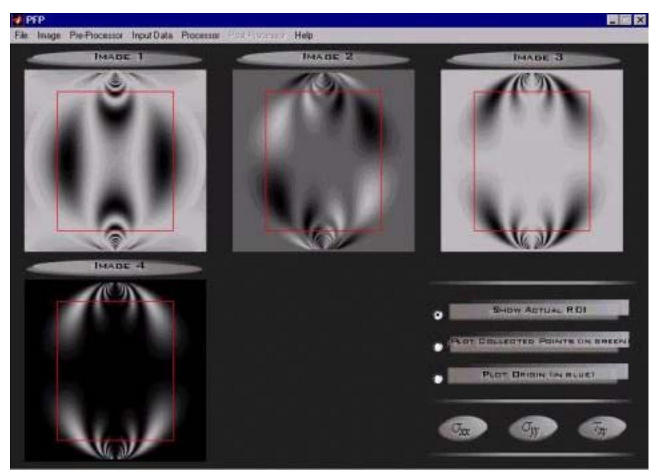

Figure 2. Four images used

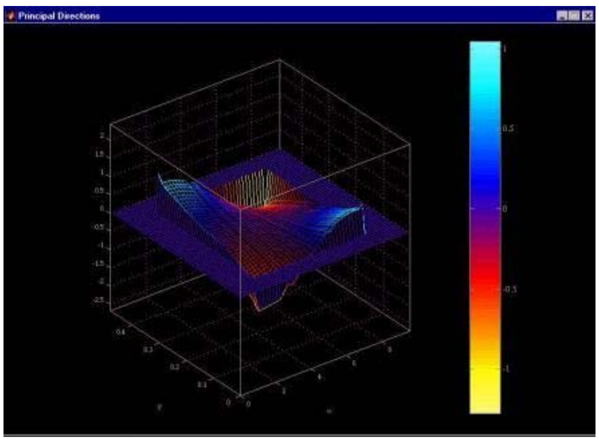

Figure 4. Unwrapped α

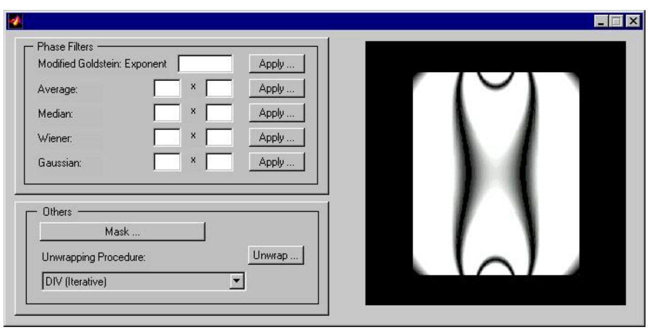

Figure 5. Fringe order wrapped phase

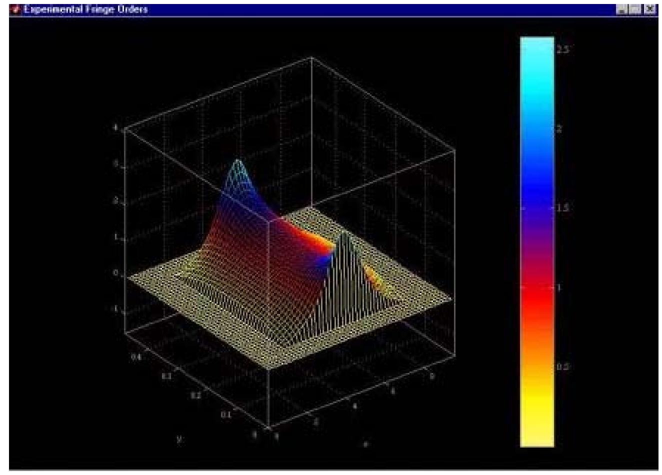

Figure 6. Fringe order unwrapped

Conclusion

Phase shifting in photoelasticity is an important tool in whole field analysis. Different ways to shift a photoelastic phase were proposed by many authors. The change in polariscope parameters has been shown to be the simplest form to do it. In this work were used a four images method, applied with image processing routines, such as blurr functions, region of interest processing, and filtering routines. Different phase unwraping algorithms were used to obtain the continuous photoelastic parameters, the direction of principal stresses and the fringe order for the whole field. An application to a disc under compression were made.

IMPACTOS DA TECNOLOGIA DA INFORMAÇÃO NA PRODUÇÃO DE PUBLICAÇÕES CIENTÍFICAS ELETRÔNICAS

Rosa Maria Villares de Souza Berto[1] and Guilherme Ary Plonskli[2]

Abstract *— This paper is a result of an academic research. A study that identifies and tracks the impacts caused by Information Technology (IT) to routines and abilities of productions and use of scientific publication, on a community of Science and Technology (C&T). It is also related to technical literature productivity, as well as, institutional visibility. This research has been developed through a study case. An auto-managed electronic questionnaire and semi-structured interviews had been used for data field collection. The e-mail was elected as the main medium of communication with the participants. Therefore, the "electronic reply behaviour" was also object of investigation. The conclusions indicate that the community assumed and legitimised the electronic communication mediated by computers. They perceive IT as a differential of autonomy, optimisation of processes, time saving and a mean of institutional visibility. Significant alterations had been identified in internal and external communication flows. They were also observed on relationships among invisible colleges and peers, on increase on the real work produced and on productivity. The scientific community recognise the benefits of remote access to bibliographical databases and to digital full texts.*

CONTEXTUALIZAÇÃO DA PESQUISA E APORTE METODOLÓGICO

O conhecimento humano é um componente fundamental na agregação de valor aos ativos de produção - tecnologia, matéria-prima, recursos humanos, informações e capital financeiro - ao potencializar competências e sustentar a competitividade de pessoas, grupos e nações. De maneira geral, toda e qualquer organização social transaciona com informação, conhecimento e saber para impulsionar suas atividades caraterísticas. Entretanto, algumas delas têm, naturalmente, vocação ao uso e geração intensivos desses recursos como as universidades, os institutos públicos de pesquisa (IPPs), as sociedades científicas e os centros industriais de pesquisas, desenvolvimento e inovação (P&D&I).

Este trabalho pretende contribuir para o conhecimento das mudanças ocorridas no processo de uso e geração de publicações científicas percebidas por uma comunidade de pesquisa em Ciência e Tecnologia (C&T), exposta às inovações da TI. As análises e reflexões aqui registradas são oriundas de pesquisa desenvolvida em tese de doutorado. O foco de observação e questionamento foi colocado nas modificações positivas e negativas que a comunicação online provocou comportamento de uso e produção de publicações científicas eletrônicas, entre pesquisadores de um Instituto Público de Pesquisa em Tecnologia Nuclear.

A pesquisa foi desenvolvida como um estudo de caso por tratar-se de um método adequado à abordagem de fenômenos sociais complexos, relativos a sujeitos com características ou natureza semelhantes. Através dele, é possível apreender a dinâmica de relacionamento entre as organizações e os indivíduos que as integram, assim como as relações que estabelecem com o meio ambiente (Marshall e Rosnam, 1995; Pereira, 1999).

Foram utilizadas diferentes fontes bibliográficas e testemunhais de dados, visando compor o cenário da situação, a partir de diferentes olhares: autores, pesquisadores, usuários, gerentes institucionais e de informação, agentes de fomento e editores científicos. Foram enviados 417 questionários eletrônicos aos pesquisadores de carreira da instituição. Os entrevistados (17) foram escolhidos por indicação interna e externa (pesquisadores e executivos da casa, agentes de fomento e editores cientifico). Os dados foram tratados estatisticamente e as entrevistas gravadas foram submetidas, após transcrição, à análise de conteúdo (discurso) e análise estatística como resume a Tabela 1.

Com essa "triangulação" pretendeu-se ressaltar os aspectos positivos e negativos que, na opinião dos todos os envolvidos, transformados em sujeitos da pesquisa, ressaltam a passagem do uso da publicação em papel para a eletrônica.

AS TECNOLOGIAS DE COMUNICAÇÃO E INFORMAÇÃO ELETRÔNICAS NO AMBIENTE DE PESQUISA

Resultado de longo e complexo fluxo de observações controladas, o conhecimento em Ciência e Tecnologia (C&T) está intrinsecamente associado à dinâmica dos processos de comunicação. A disseminação de novas idéias é parte integrante das práticas de pesquisa e promovem trocas de informação entre indivíduos e grupos de interesse, através de meios especializados (Levy, 1993).

A Ciência propicia reordenações sociais e, ao mesmo tempo, recebe da sociedade respostas que iniciam novas demandas. Nesta linha, as inovações à Tecnologia da Informação (TI) e aos processos de comunicação eletrônica provocam reações variadas nas esferas sociais que sensibilizam. São ferramentas inéditas de acesso e divulgação de conhecimentos de toda ordem. Utilizam recursos tecnológicos de informática e telecomunicações para registrar e disseminar informações via redes eletrônicas de computadores (Van Der Kam et al., 2000).

Têm provocado mudanças irreversíveis não só aos processos de troca de informações como também às condições de inclusão de pessoas e organizações no mundo digital. Em particular, transforma processos e relações estáveis entre segmentos sociais específicos, dos quais recebe aprovação e/ou desprezo (Castells, 2000; Webber e Johnston, 2000).

Especialistas de diferentes áreas do conhecimento buscam identificar causas e efeitos desse complexo jogo entre as estruturas e as relações sociais, onde tecnologia é focalizada com destaque (Harnard, 1995; Dervin, 1998, Orlikowski, 1992; Friedlander, 2001). As tecnologias da informação e da comunicação modificam os processos e relações de produção na medida em que pressionam a sociedade a adotar formas inéditas de operação. O conhecimento e a informação substituem, em grande parte, o capital e o trabalho enquanto variáveis econômicas de agregação de valor. A informação emerge como força produtiva dominante, modificando a lógica da economia e do regime tradicional de acumulação de riquezas. Também amplia e estimula os investimentos desmaterializados como P&D, licenças e registros de patentes e treinamento especializado (Dantas, 1999).

As vantagens competitivas baseadas em atributos materiais deslocam-se para características como valor de mercado, tecnologia, design, formação profissional, marcas e grifes. A relativização do tempo e do espaço nos ambientes digitais e cibernéticos também são fatores de impacto ao descaracterizar os esquemas e processos de vigentes de organização do trabalho e da produção (Herkert e Nielsen, 1998; Stanworth, 1998).

Não é possível afirmar que uma nova tecnologia, quando introduzida em um ambiente organizacional, é benéfica por si. É necessário que ela se integre ao sistema social vigente através de mecanismos particulares e únicos de assimilação. Nesta ótica, a incorporação de novas de tecnologias é, em maior ou menor grau, modelada e apropriada pelos grupos sociais, através de conceitos e abordagens próprias (Rosenbaum, 1997). Avaliações pragmáticas e empíricas sobre impactos das inovações tecnológicas dão conta de que, no curto e médio prazos, as vantagens à elas associadas desestabilizam os padrões sócio-econômico-culturais vigentes (McMurdo, 1996). No entanto, por sua origem e função, a tecnologia também está exposta às pressões e reações da sociedade.

Ambas as posições visam antecipar que mudanças nos cenário social, econômico e político podem ser esperadas à medida que a TI é difundida entre as várias dimensões sociais. Assim sendo, é importante observar como as comunidades científicas reagem às pressões para adoção de novos modelos de registro e difusão do conhecimento, fundamentais `a produtividade e visibilidade no seu meio ambiente.

As pressões de mudança imprimidas pela TI estão presentes em todas as atividades P&D&I, inclusive na produção e divulgação de registros do conhecimento acumulado, representadas pela publicação científica. Assim sendo, os modelos tradicionais (não eletrônicos) de criação, arbitragem, edição e disseminação do conhecimento em C&T, também estão sendo estruturalmente modificados pelas inovações aos processos de comunicação (Ubell, 1997; Gomes e Meadows, 1998; Sabbatini, 1999; Costa e Meadows, 2000). Neste novo cenário, Maculan e Soares (2000); Costa (2000) e Hurd (1996 e 2000), afirmam que o processo de produção de publicações científicas eletrônicas está buscando uma identidade própria.

MODIFICAÇÕES À LÓGICA DE PRODUÇÃO DE PUBLICAÇÕES CIENTÍFICAS: DO ACERVO AO ACESSO

A comunicação eletrônica fez com que a lógica do acervos bibliográficos baseados na garantia literária dos documentos impressos fosse substituída, em parte, pela lógica do acesso, ou seja, pela gestão de conteúdos multimídia. Gradativamente, as práticas orientadas por um modelo analógico migram para outro, de natureza digital (Min e Rada, 1994). Da mesma forma, os processos de organização e tratamento dos dados deverão alterar, sobremaneira, os procedimentos clássicos de concepção (projeto) e geração (produção) de produtos de conteúdo digital (Cox, 1998).

Nesse momento, é perceptível o caráter ambíguo das facilidades e restrições na oferta de produtos eletrônicos do conhecimento e, em particular, da publicação científica eletrônica. Na busca de uma identidade própria, haverá um momento de ruptura nos conceitos e na lógica de operação de ambos os modelos (Lancaster, 1995; Costa et al., 2001; Friedlander, 2001)

Até meados dos anos 80, o trabalho baseado no conhecimento era orientado à provisão de serviços e produtos de informação baseados em papel (registro, armazenamento e recuperação).

A passagem da "economia industrial" para a "economia digital" promoveu a evolução de conceitos, tecnologias, formatos, suportes e mídias. O novo foco amplia, evolui e diversifica o escopo da atividade. Apesar de modificações aos processos vigentes, não é possível afirmar que as práticas tradicionais da "era industrial" foram ou mesmo que serão abandonadas no futuro. O foco está sendo deslocado:

- do suporte material, recipiente ou embalagem para o conteúdo e a mensagem;

- do texto impresso, linear e estático para a dinâmica de navegação por hipertextos;
- da pesquisa e acesso locais para pesquisa e acesso remotos;
- da postura reativa (suprimento da demanda explicitada) para a proativa (provimento da demanda potencial);
- da linguagem controlada para a linguagem livre;
- de acervos físico-materiais para acervos ótico-digitais;
- de sistemas isolados para redes integradas;
- de processos pré-concebidos (produtos de prateleira e customizados de massa) para produção sob encomenda, diferenciada ou pós-formatada;
- da garantia de permanência dos registros (longa vida útil do papel) à incerteza dos suportes magnéticos e eletrônicos;
- da gestão da informação para a gestão do conhecimento;
- de grandes volumes de papel para pequenos e diversificados lotes de produtos de informação.

Como qualquer atividade produtiva, os processos de geração e entrega de bens do conhecimento (produtos de informação) envolvem:

- a geração (criação de dados e fatos inéditos e/ou captação no meio ambiente);
- o processamento (reelaboração, ou seja análise e codificação da "matéria-prima" para sua melhor utilização);
- o armazenamento (estocagem de produtos acabados ou semi-prontos até que possam ser distribuídos); e
- a distribuição (entrega de bens em formato, meio, volume e tempo determinados pelo cliente). Podem ser desenvolvidos por uma única pessoa ou empresa ou por um conjunto de parceiros (Zack, 1996; Loges e Jung, 2001).

O conceito mais recente de produto de conteúdo vincula-o, em definitivo, ao ambiente digital WWW. Pode ser definido como unidades ou conjuntos de dados, textos, sons, imagens e suas combinações multimídia, apresentados em formato analógico ou digital e registrados em memória magnética ou óptica (SOCINFO, 2000).

Atributos como precisão, atualização, oportunidade, flexibilidade e customização são características esperadas de produtos de conteúdo ditos, de qualidade. Como aspectos positivos para sua produção e consumo podem ser lembrados:

- possibilidade de entrega eletrônica, em diferentes formatos e tamanhos;
- desenvolvimento de novos tipos de demanda e clientes; e
- modelos inéditos de agregação de valor (autor - editor - publicador - distribuidor - agentes de intermediação - usuário).

Quanto às restrições e os desafios, são representados por:

- relação com parceiros ou com clientes;
- criação e manutenção de infra-estrutura de produção e veiculação;
- políticas de investimentos, de preços e de promoção; e
- defesa de propriedade intelectual.

A nova ordem digital apresenta situações onde as facilidades e restrições do mundo eletrônico misturam-se às referências e rotinas do mundo analógico. Apesar das vantagens que apresenta, ainda existem questões complexas a serem equacionadas. Referem-se à política de preços, versões gratuitas, propriedade intelectual, dificuldades ergonômicas, barreiras culturais, conteúdos arbitrados, entre outras (Harnard, 1995).

Para Kling e McKim (1999, p. 891), a publicação eletrônica "é um documento primariamente distribuído através de meio eletrônico. O meio de distribuição é o fator que define sua natureza pois uma publicação eletrônica pode ser impressa, a posteriori, para leitura e circulação". A elaboração e formatação do texto através de computadores e softwares especializados também reforçam sua natureza eletrônica.

As transformações radicais estão concentradas na logística do processo pois a conectividade e a acessibilidade permitidas pela tecnologia e pelos canais, meios e equipamentos de transmissão, alteram os padrões tradicionais de entrega do produto e seus desdobramentos. Referem-se ao acesso a textos integrais, interseção de textos, seleção e elaboração de perfis de interesse, bancos de endereços eletrônicos, remessas e cobranças automáticas, suporte ao cliente. Trata-se de mais um diferencial no processo de agregação de valor (Harnard, 1995; Harter e Park, 2000).

A conquista definitiva de confiança dos usuários de publicações científicas eletrônicas está diretamente ligada à garantia de que os atributos de acessibilidade, confiabilidade e publicidade, centrais nos modelos baseados no papel, sejam preservados e consolidados no suporte eletrônico.

A portabilidade do meio permite eficiência no acesso e na transferência, seleção e organização em bancos de dados, reordenação de formatos, uso de partes do texto sem necessidade de redigitação.

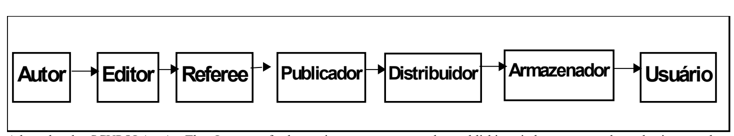
Em contrapartida e apesar das questões ecológicas, o papel tem seu lugar garantido na facilidade de manuseio, portabilidade e possibilidade de contato, visão do todo, forte padrão cultural e barreiras tecnológicas menos restritivas - falhas técnicas, inoperância e incompatibilidade eventual entre sistemas e redes (Wurman, 1992).

MODELO DE PRODUÇÃO DE PUBLICAÇÕES CIENTÍFICAS ELETRÔNICAS

Nos modelos econômicos globalizados crescem as exigências por condutas adequadas aos processos não poluentes, baixa escala e/ou diversificação da produção, baixo consumo de matérias-primas e energia, uso intensivo da tecnologia de informação e ênfase nas habilidades e qualificações humanas.

A Figura 1 demonstra as possibilidades de relação e acesso entre os diversos elos da cadeia de produção de bens e de agregação de valores. Cada combinação supõe uma forma específica de arranjo técnico e acesso eletrônico.

Figura 1: Atores da cadeia produtiva de publicações científicas



Adaptado de SCUPOLA, A. The Impact of electronic commerce on the publishing industry: towards a business value complementaring framework of electronic publishing. *Journal of Information Science*, v.25, n.2, p.135, 1999.

A modificação estrutural da informação contida nos relatos científicos e acadêmicos, não mais circunscritos à lógica linear de um texto impresso, proporcionam interação direta e multidirecional ao conteúdo (Barreto, 1999). Kling e McKim, (1999) indicam que apesar de reestruturados, os movimentos de produção permaneceram inalteradas. O que muda é a relação tecnologia - suporte - veiculação.

Os aspectos ligados à cultura da confiabilidade das publicações, devem e precisam continuar os mesmos. É necessário acessibilidade, confiabilidade e publicidade independentemente do seu meio de geração, distribuição e acesso.

COMPETÊNCIAS PARA A PRODUÇÃO DE PUBLICAÇÕES CIENTÍFICAS ELETRÔNICAS

As tecnologias de base eletrônica criaram demandas por novas competências de produção. A consolidação do setor será validada pela capacidade de resposta de seus profissionais aos desafios que se apresentam (Harnard, 1995; Rowley, 2000).

A gestão do conhecimento propicia a adaptação e a adequação de aspectos organizacionais críticos à sobrevivência e à soberania das empresas, face às instabilidades ambientais. Não obstante às facilidades e à precisão conseguidas através de técnicas avançadas, os processos de combinação e sinergia nos ativos de informação têm como característica-chave a inclusão das pessoas que agregam valor à informação (Sviokla, 1996).

A questão cultural da mudança é a variável mais difícil de ser entendida e controlada. Os profissionais de informação, como bibliotecários e jornalistas são, potencialmente, os principais agentes na modificação de atitudes e comportamentos relativos à mesma (Davenport, 2000). Ainda segundo o autor, corroborado por Bock (1999), pela natureza da função e do conjunto de instrumentos e estratégias de abordagem dos segmentos usuários, esses profissionais podem influenciar as mudanças e a remoção de preconceitos sobre ambiente eletrônico e seus produtos (Hickey, 1995; Mahroum, 2000).

Também está fortemente condicionada ao estabelecimento de relações saudáveis consistentes entre consumidores, provedores e promotores de informação. Trata-se de uma área de negócios em expansão, para a qual os IPPs poderão ser beneficiados, através de parceiras. Diferentes segmentos sociais poderão associar-se às comunidades científicas, para provimento de conteúdo avaliado e reconhecido para portais temáticos de C&T, bases de dados especializadas, aplicações educacionais e multimídia (Stephenson, 1998).

Outro desafio para o setor e seus profissionais está na complexidade de recuperação de registros não inscritos em tecnologias digitais, assim como os "ruídos" na busca de publicações ou páginas eletrônicas sem a chancela do conteúdo avaliado. Devem ser consideradas as questões éticas, legais, financeiras e de credibilidade relacionadas à veiculação e à exploração de direitos autorais de conteúdos em ambientes como a Internet.

Com base nos trabalhos de Hietink (1997) e Borgman (2001), recomenda-se a criação de programas de orientação aos autores e usuários de publicações científicas eletrônicas. Devem abordar os pontos-chave do produto, em seus aspectos fortes e fracos, pautando-se por considerações quanto à:

Acessibilidade

- garantia de permanência do documento na Web, por um longo período e, principalmente, se foi efetuada alguma publicidade ou divulgação da obra.
- Registro da publicação em algum meio eletrônico eficiente e durável (permanente) de registro magnético.
- Acessibilidade garantida por um meio ou endereço eletrônico confiável e disponível online a qualquer tempo ou período.
- Disponibilidade a qualquer cidadão ou membro da comunidade de acordo com as regras estabelecidas para acesso (gratuito, pago, senha).
- URL - Unified Related Locator (endereço eletrônico) estável e permanente.

Confiabilidade

- Conteúdos não podem ser modificados, indiscriminadamente.
- Diferentes versões de um mesmo documento devem ser claramente identificadas.
- Confiabilidade baseada em padrões institucionalizados e reconhecidos de credenciamento como um sistema de arbitragem e o própria credibilidade do autor.
- Deve possuir autoria explicitada com, pelo menos, um autor devidamente identificado (nome, instituição, endereço).

Publicidade

- O público ou os usuários potenciais devem ser informados, de alguma maneira, da existência da publicação.
- A publicação necessita gerar ou possuir uma quantidade suficiente de metadados e outras informações que a identifiquem e que possibilite sua recuperação direta ou através de metabuscadores.

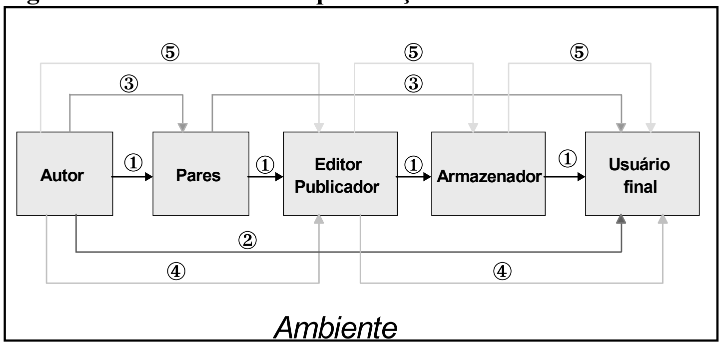
A Figura 2 mostra as várias possibilidade de se publicar na Web. O esquema clássico e modular ①inclui todos os atores e movimentos herdados do processo em papel. É perfeitamente transferível para ambientes eletrônicos e, para alguns casos, é o mais indicado.

No entanto, outras combinações podem ser efetuadas. O autor pode disponibilizar seu texto/publicação na Web e sensibilizar diretamente o usuário final ②.

Pode ainda, em uma terceira variante, submeter seus conteúdos ao processo de avaliação e referagem e, em seguida disponibilizá-lo na rede, através de sites pessoais e/ou temáticos ③.

Outra chance ④está na passagem da origem (autor) `a produção gráfico-editorial para então chegar aos leitores. A última forma ⑤, inclui o autor, o editor/publicador, o armazenador e o usuário final.

Figura 2: Possibilidades de publicação em ambiente eletrônico



① Do autor para os pares, para o editor, para o publicador, para o armazenador, para o usuário final

② Do autor para o usuário final

③ Do autor para os pares e para o usuário final

④ Do autor para o editor/publicadores, para o usuário final

⑤ Do autor para o editor/publicador, para o armazenador, para usuário final

As bases teórico-conceituais tratadas nesta parte, encaminham esse relato `a sumarização dos resultados aferidos no processo de pesquisa.

OS RESULTADOS: MUDANÇAS E DESAFIOS

De maneira geral é possível afirmar que a acordo com o modelo da estruturação de Giddens (1989), a comunidade científica pesquisada percebe claramente que as inovações tecnológicas na comunicação eletrônica modificaram suas rotinas e processos de trabalho.

Ao alterar o acesso e a difusão do conhecimento (comunicação, normas e significação), a TI alcança e modifica as competências profissionais dos sujeitos, da concepção à operação e gerenciamento do processo produtivo (poder, procedimento e dominação). Os parâmetros de avaliação de resultados e produtividade (sanção, condutas e legitimação) também foram reconsiderados. Porém, são perceptíveis e ativos os filtros de aceitação e rejeição criados pela comunidade, frente àquelas pressões.

Os ambientes de pesquisa possuem, naturalmente, predisposição em avaliar e assumir inovações. Na coleta de dados e, principalmente nas entrevistas, foi possível registrar depoimentos de pesquisadores que estão à frente do "tempo digital" da maioria das pessoas. Talvez por isso mesmo tenham sido indicados para o contato.

No geral, o grupo estudado está em fase de conhecimento, experimentação e eleição das facilidades proporcionadas pela TI. Usando o depoimento de um entrevistado "eu sinto que estão surpresos: ao mesmo tempo eufóricos e assustados".

As transformações são encaradas como fator de desenvolvimento que pressiona e remove antigos padrões de conduta. Percebe-se que alguns foram rapidamente substituídos e assimilados, como os referentes aos meios de comunicação. Outras mudanças, como a atividade de publicação científica, seguem um pouco mais devagar.

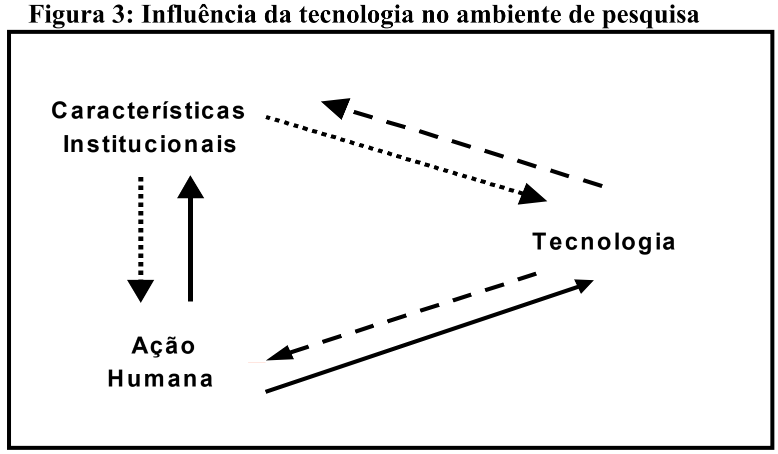
O fato talvez se relacione, diretamente, com a urgência e a necessidade primeira e constante de comunicação. É a base para que todos os outros componentes possam ser utilizados e, necessário, modificados.

Ficou claro que as pessoas estão se integrando ao novo modo de operação. É um processo que demanda tempo e trabalho pela existência de componentes culturais fortemente incorporados (como o uso de documentos impressos) e diferenciados no comportamento de cada grupo (hábitos, motivação e valores para publicação).

Os aspectos de segurança, confiança e autonomia estão privilegiados nas falas da população pesquisada. Através delas foi possível inferir que possuem capacidade de ação, interação e intervenção em processos e rotinas que envolvam tecnologia de informação. Com alguma criatividade e reforço externo, sua condição natural de "puxar e proagir" pode ser aproveitada e estendida aos membros menos ativos da comunidade.

A informática foi criada e se ampliou, integrando a TI por ação humana. Agora e mais uma vez, modifica as rotinas humanas em função de facilidades e condições de uso que apresenta. Essa é a característica básica da recursividade ou dualidade da tecnologia, como está colocado na Figura 3, ‘a página anterior. Ela indica que em ambientes de Ciência a Tecnologia também é fonte de pressão. Estrutura-se e amolda-se de acordo com as reações e tempos de assunção de cada comunidade, em particular (ações humanas).

Figura 3: Influência da tecnologia no ambiente de pesquisa



Processo interno e externo de comunicação

Na comunidade estudada, a Web já é central como estratégia e veículo de comunicação. Reforça e suprime outros canais de comunicação, modifica posturas e procedimentos de trabalho e tem graus de aceitação maiores ou menores, mais rápidos e mais lentos.

Especificamente para a comunicação, as mudanças foram muito bem aceitas e incorporadas pela comunidade. Na pesquisa, todas as perguntas que envolviam comunicação eletrônica foram maciçamente indicadas como primeira fonte ou primeiro recurso.

É perceptível que as organizações em geral e, em particular, as instituições de pesquisa em C&T, estão transferindo seus fluxos de comunicação e informação baseados em papel pelos registros digitais. A característica principal da primeira é a estabilidade e permanência. Porém, traz como herança, volumoso legado em papel. A maleabilidade e a flexibilidade dos aportes digitais trazem consigo a ambigüidade e instabilidade que podem gerar desconfiança. Seu processo de apropriação deve envolver todos os participantes pois a tecnologia é flexível e a interação dos diferentes contextos sócio-históricos se faz através da interseção de relações e comprometimento.

Da análise dos dados recolhidos, foi possível concluir que as mudanças referentes à comunicação foram bem aceitas. A comunidade reconhece e valoriza o esforço institucional de atualização tecnológica, tanto na modernização de processos (acesso à Internet/Intranet) como na melhoria da infra-estrutura (expansão da rede física e outras instalações).

Também espera que a comunicação organizacional seja exteriorizada através de estratégias de organização eletrônica do conhecimento (sítios, bases e páginas Web) e em processos específicos de gestão do conhecimento (técnico, científico e organizacional).

Comportamento de busca, uso e credibilidade de publicações científicas eletrônicas

Constatou-se o comprometimento e o envolvimento do grupo pesquisado quanto aos novos modelos eletrônicos de comunicação - mas não, necessariamente, com aqueles de publicação científica. A ausência de um programa instituído de publicação científica foi citada de várias formas e em vários depoimentos. Parece urgente e estratégico que sejam efetuadas ações que corrijam esta disfunção.

No esforço da formação de consumidores e produtores de documentos eletrônicos, são necessários procedimentos mercadológicos e campanhas de esclarecimento sobre as reais possibilidades e limites do novo meio.

Quanto ao processo de publicação eletrônica, como um todo, percebeu-se que alertas válidos e significativos convivem com alguns mitos sem fundamento. O que para alguns é apenas mudança de formato, por outros já é percebida como profunda e irreversível transformação. Características aparentemente físicas e externas da publicação, seu suporte material, agora sensibilizam as esferas ideológicas da questão. Todas as estruturas (recursos) dessa cadeia produtiva estão sendo transformadas: dos aspectos mais evidentes aos mais teleológicos.

Através dos depoimentos e das entrevistas foi possível identificar que cada ator não sabe, exatamente, o que incomoda mais pois o transtorno está diluído por todo o processo. Autores, editores, publicadores, bibliotecários, gestores e usuários buscam explicações e soluções ao seu universo imediato. No entanto, além de um fórum ampliado e permanente de discussões que privilegie todos os elos dessa cadeia, é necessário um certo período de tempo para identificação e observação dos fenômenos.

Algumas referências podem ser potencializadas nesse processo. O sistema de arbitragem por pares é central em sua escala de valores e exigências. É central na atividade baseada em papel e assim deve permanecer na digital. Esse pode ser o lastro mais significativo na credibilidade e difusão das publicações eletrônicas.

Da mesma forma, as normas e legislação existentes não se adequam ao novos suportes por basearem-se na materialidade do papel. É preciso urgência na reorganização desse referencial. Até os processos de aquisição de material bibliográfico estão sendo afetados. Nas instituições públicas, por exemplo, à cada compra ou empenho aprovado é atribuído um lote de patrimônio, um objeto físico que deverá ser cadastrado à sua entrega. Como se cadastra e se patrimonia uma transmissão online? Como guardá-la? Como registrá-la?

Atividades de editoração atingem, preferencialmente os editores. Porém, é importante que estes falem do seu trabalho, facilidades, crenças e verdades aos outros "elos" da cadeia. O problema é que fazem parte da mesma cadeia mas não são, necessariamente, parceiros. Portanto, o contato fica comprometido.

Comportamento de produção e disseminação de publicações eletrônicas

A adoção, pelos pesquisados, dos processos de comunicação eletrônica e das facilidades Web, podem ser aproveitados para capacitação paralela – para a geração de publicações eletrônicas - à medida em que se consolidam os hábitos e a confiança pelo uso da inovação. No caso, associando-lhes funções importantes e corriqueiras através da rede: busca e recuperação de dados e informações; envio de documentos únicos ou em lotes e produção de textos coletivos digitais. A criação de setores virtuais de inteligência e armazenamento coletivo de informações nos IPPs podem ajudar na "vascularização" dos fluxos internos e externos de informação.

Todavia, é preciso conhecer os perfis dos grupos envolvidos, sintonizando demanda, necessidade e oferta de soluções. A adesão e o reforço aos canais de comunicação eletrônicos faz transformar outros aspectos da vida dos cidadãos. Estar ligado 24 horas na Web e no e-mail é condição importante para uns. Outros, no entanto, se sentem invadidos pelo trabalho, pelo tempo e pela tecnologia.

Os periódicos científicos arbitrados continuam sendo os preferidos da maioria, principalmente agora que estão mais acessíveis (textos integrais). O trabalho de desmistificação - se for o caso - das publicações eletrônicas pode começar por eles!

A comunidade parece aberta à inovações desde que seja (ou esteja) convencida, segura ou se sentido livre, autônoma. A questão da autonomia na Web é ambígua, como a própria instabilidade digital. Qualquer modificação ou falha no sistema ou na rede física (externos, estruturais e poderosos) deixa a todos reféns da situação!

Capacitação para produção para publicação científica eletrônica

A habilidade de criar, armazenar e acessar informações e documentos digitais é fundamental à permanência e soberania das empresas e das pessoas. Nesse caso, a gestão do conhecimento enquanto um processo de monitoração ampliado, pode diferenciar as organizações

Ao organizar o fluxo contínuo (e eletrônico) da informação preserva a memória, a história e o futuro da organização. É propício à implementação de Programas Institucionais de Comunicação e de Publicação e de Sistemas de Gestão do Conhecimento. Velocidade de processamento, capacidade de reunir maior número de dados é o que têm feito diferença. No entanto, em respostas às pressões da TI, a comunidade estudada tem assumido apenas o que lhe parece seguro e adequado.

Estratégias políticas e mercadológicas poderiam ser introduzidas ao seu ambiente principal: Programas de Incentivo à Publicação Eletrônica, Clube de Autores Virtuais, Programas de Formação de Editores Científicos Web, e treinamentos que otimizem os recursos Web. E ainda, palestras de esclarecimento sobre as publicações científicas eletrônicas em que os autores, as instituições de pesquisa, as agências de fomento, as editoras e os prestadores de serviços pudessem ser envolvidos e associados.

Modelo de relações estruturais para a produção de publicações científicas eletrônicas

Na Figura 4 está proposto um modelo de relações e organização dos aspectos estruturais que integram o processo de produção e disseminação de registros eletrônicos do conhecimento. Basicamente, as relações devem ser ampliadas e espelhadas ao longo da cadeia produtiva, aproveitando-se as posssibilidades de comunicação dirigida e múltipla. Facilitam o entendimento, a cooperação e as transações dentro da mesma cadeia.

PRODUCING DISTANCE COURSES WITH XML

Amine Benkiran Rachida Ajhoun Borlli Michel Jonas SOME

Abstract

To take advantage of the asynchronous telelearning, documents representing courses must fit appropriate characteristics. The most important of these characteristics is the ability of the courses to adapt itself to the learner profile. The courses must also be interactive, structured, multimedia, web compatible, etc.
The purpose of this paper is to show how using XML and its associated tools is the way to fit all of these characteristics. It also describes the manner these characteristics are integrated.

Keywords

Tele-learning, distance courses, XML, adaptativity

1 Introduction

This study is a part of the SMART-Learning (System for Multimedia Adaptative and coopeRative TeleLearning) project at the RIM research unit (Réseaux Informatiques et Multimédia) at EMI. The goal of this project is to provide courses to distant learners without any space or time constraint, including the possibility of having synchronous sessions (real time) for the conversation between the various actors intervening in the process of learning (learners, trainers...). In addition, the fundamental goal is the adaptability of the courses to the learner according to pedagogical requirements and learner capabilities [1].

Generally, courses that are available on the Internet are hypertext documents. The structure of the hypertext and the reading modes it leads to are opposed to some educational principles. A learner can access any pedagogical sequence of a course without order constraints of these sequences and without having the preliminary knowledge. Consequently, the teaching objectives (specialty, type of training...) aimed by the access to the course will not be reached. In our view and to ensure a pedagogical learning, the course must take account of the learner profile (capacities of training, previous knowledge, language,...) and the learner evolution (prerequisite, speed of knowledge acquisition...)[2].
Another limitation of the hypertext is that the course has no structure and its content is mixed with presentation markers, which makes it impossible to automatically process the course.

In order to meet the courses needs in telelearning, it is necessary that the course document fits the following characteristics:

(i) The course must be a hypermedia or at least a hypertext document, in order to guarantee the interactive aspect of the course,
(ii) It must moreover be written in a syntax allowing it to be put on the Web,
(iii) The course document must be able to reproduce the course structure and contents,
(iv) It must also be modular. A course part can be added or updated without changing the whole structure,
(v) The document must be structured so that its manual or automatic processing is easy,
(vi) The course document must respect a course model previously defined on pedagogical bases,
(vii) The structure as well as the content must be independent of the presentation aspect of the course in order to allow the modification of the document style in a global and content independent manner,
(viii) The course is a hypermedia document that must be able to guarantee the synchronization (or scenarization) of the media it contains,
(ix) Finally and overall, to guarantee the adaptability of the courses which is a very important feature allowed by the telelearning.

We will show, in the continuation of this paper, how XML and its associated tools make it possible to guarantee, to the documents which represent our courses, the characteristics that we have just listed. We applied and tested these methods in our SMART-Learning system.

2 Course characteristics in SMART-Learning

SMART-Learning is mainly asynchronous. It provides courses to distant learners without any space or time constraint. The objectives of the SMART-Learning course structure is to fit the characteristics defined above and take advantage of the asynchronous telelearning.

The power of SMART-Learning appears in the ability of the courses to be adapted according to the learner profiles, as well as the ability of cooperating through the document.

We are mainly interested in presenting the model for structured and adaptative courses in the Internet (characteristic (ix)). The course structure is essential to satisfy the objectives listed above including the adaptability objective in SMART-Learning. It must allow the production of a generic course which will be used to generate a specific course at the moment of the training

‡ Borlli Michel Jonas SOME, UFR Réseaux Informatique et Multimédia, Ecole Mohammadia d'Ingénieurs, BP 765, Rabat Agdal, borlli@emi.ac.ma

(figure 1). This model provides the general structure of a course in such way that the sequences presented to the learner are adapted to his profile and to the training level he wishes to reach.

Figure 1 shows how adaptability is processed in SMART-Learning. This schema will afterwards be realized using XML technology which is the only one that allows, in the same time, the adaptability and the other characteristics.

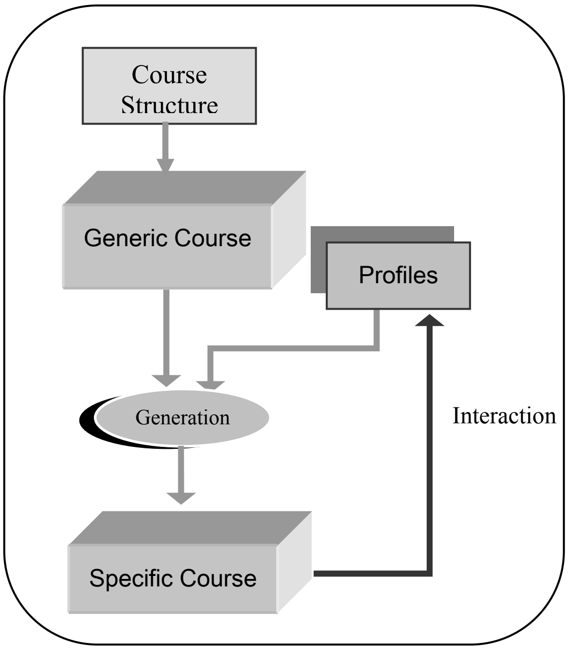

Fig. 1: Learning Process in SMART-Learning

The generic course is intended for all profiles. It is a document which contains, in addition to the learning material, the pedagogical expertise of the trainer. A generic course must take into account the various objectives pursued by the course and the various profile types of the learners who will have access to the course.
This approach makes it possible to generate for each learner, based on his profile, a specific course by using a generation system (figure 1) during the training while the learner is accessing the course. If, for example, the learner profile is modified following the result of an evaluation, the course will be automatically regenerated so as to consider the new knowledge obtained by the learner.

3 Course structure in SMART-Learning

In order to fit the above listed characteristics as well as the pedagogical process, we defined a structure for the course document of SMART-Learning which will be then represented in XML

The production of a course is based on an educational design, which is used to structure the contents in order to facilitate the learning. The course structure must take into account the following criteria [3]:

- To stratify information in order to take account of the complexity levels and to adjust it with the preliminary knowledge of the learner (characteristic (ix));
- To structure the presentation in media elements in order to facilitate the selection, the organization and the integration of information to be presented to the learner (iii, vii, ix);
- To produce the course in several languages in order to improve its deployment for a larger number of possible learners (ix);
- To consider the use of various media (text, audio, video...) which encourages the learner to take a telelearning course (i, ii, viii),
- To take in consideration all the details, even the optional sequences of the course (illustrations, reminders...). In a traditional teaching, the trainer is present at the time of the training and can add missing information or make a not initially considered reminder, whereas in a telelearning application, if the contents of the reminder are not initially considered, teaching will be then defective (i, iii),
- To have a hierarchical structure to represent the course document (iii, iv, v).

The generic course is then seen like a set of pedagogical sequences (PS) structured as a tree with a single root (figure 2). Each sequence constitutes a distinct whole. It can be a course, a chapter, an evaluation or other. A pedagogical sequence (PS) is then broken up into other pedagogical sequences or elementary pedagogical sequences of the lowest granularity. The leaves of the tree constitute the contents to be presented to the learner, they are the media elements (ME).

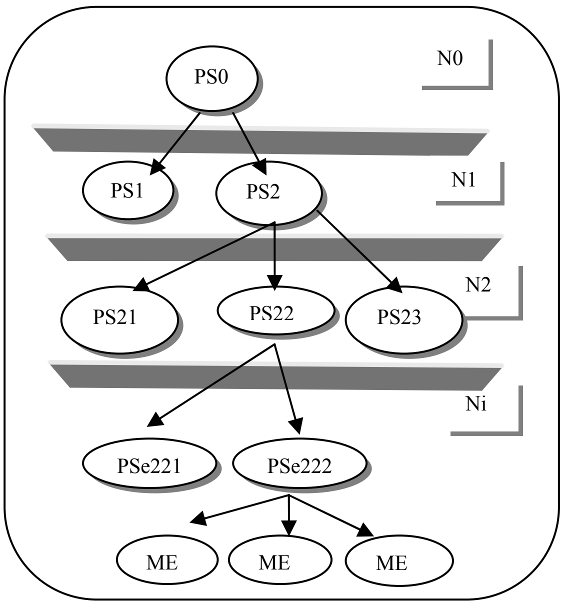

Fig. 2 : Course structure example

Moreover, this structure is valid for any courses whatever the teaching modes to which the designer is used (module, course, unit, etc) to conceive his course. All he has to do is to use the equivalence interface of SMART-Learning. This interface guarantees the equivalence between the terminology of our structure and that used by the course designer [4].

For adaptability reasons, each component (PS, PSe and ME) is annotated by a set of selection criteria which will be used by the learning process in order to generate or not the component according to the learner profile at a given moment. Thus, we defined four categories of selection criteria :

- Educational : this category describes the educational criteria that the course designer must define before the production for training needs. The most significant is "the pedagogical objective". For example, "engineer training" or "technician training";
- Psychological : this category describes all the psychological factors which determine the way of learning. For example, the understanding level;
- Localization: this category describes all the criteria which facilitate and improve the communication between the course author and the learners. For example, the course contents language and other regional characteristics;
- Technical : this category describes the technical needs (flow, hardware characteristics,…) to generate the components which will be presented to the learner according to his environment.

This structuring approach makes it possible to keep the same course structure and to change, for each profile, only the part of the contents which relates to it. It also makes it possible to avoid the errors which result of updating different course versions intended for different profiles. For example, the update of the contents of the PS1 (figure 3) is done only once for the two types of training (engineer and technician) instead of updating two different versions, one for the engineers and the other for the technicians, which could easily involve errors or omissions [2].

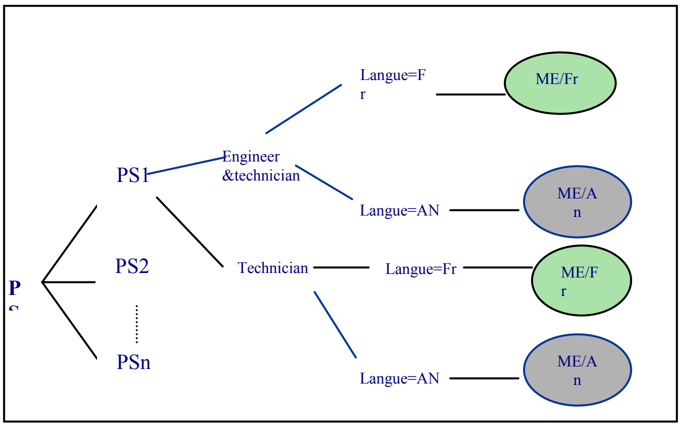

Fig. 3 : Example of relations between the criteria

4 XML AS A SOLUTION

HTML is, of course, the first solution which comes to mind for representing a course on the Internet. However, it fits only three of the characteristics we defined (i, ii and viii).

The XML language, reputed by its facility to exchange complex document on the Internet, is in fact the ideal solution to fit all SMART-Learning and telelearning courses characteristics we defined earlier. XML comes with a set of tools based on XSL, DTD-Schemas, CSS and parsers.

4.1 Hypermedia structured documents on the Web

The eXtensible Markup Language (XML) allows to write hypermedia course documents (i, ii) just like the HTML, but gives in addition the possibility of defining new personal tags contrary to the HTML which presents an extremely rigid and present tagging set.

The possibility of creating his own tags makes it possible to represent any type of document and thus the courses which we defined with adapted tags. The hierarchical structure of XML corresponds to the course structure of SMART-Learning (fig. 2) and thus fits the characteristics (iii and iv).

The automatic processing of course documents (v) is made possible by the XML associated parsers like XT of James Clarck [6], Xalan from Apache [7] or others. The tagging language also allows, by the means of name spaces, the use of several vocabularies in the same document. We can, in particular, represent the tags corresponding to the course structure and the tags corresponding to rules of time precedence between the elements. The synchronization language SMIL (Synchronized Multimedia Integration Language) integrates in this manner into any XML document and thus a course. It conforms, itself, to the XML syntax. In SMART-Learning, the media elements could thus be sequenced and scenarized (viii).

4.2 Definition of course types

It is important, in any telelearning system, to be able to define a course model which corresponds to a pedagogical or presentation method that all the courses must respect (vi).

XML allows it using the DTD (Document Type Definition) concept which is a model which makes it possible to define a document class for SMART-Learning courses. Each document corresponds then to an instanciation of the DTD. Schemas are even more flexible than DTDs to define more rigorous documents types.

3.3 Separation between content and presentation

The great drawback of HTML is the mixing of the content and the presentation instructions (format, style) in the same document. This makes the contents very difficult to locate and thus to update. It is also very delicate to apply the same presentation style on the same level of text, the section titles or the listings, for example.

These difficulties are overcome (vii) with XML and the associated tools. The structure and the contents of the document are described in an XML document whereas the presentation is defined in an associated document which can be described with several style definition languages depending on the desired presentation. We currently use the first version of CSS. CSS2 will allow much more possibilities when it is recognized by the various browsers. These possibilities will be more increased with the even more complete language XSL:fo.

Current browsers visualize XML documents. However, not all of them recognize the whole set of the XML associated tools functions. It is however always possible to transform an XML file into HTML using XSLT by associating formats described in XML to it. The transformation into HTML allows the document to be then visualized on any browser. This phase will be definitively abandoned when all the browsers are able to recognize XML and its tools.

4.4 Course adaptability

The adaptation of the course according to the user profile is made possible using XSLT. It will first of all be necessary to adopt a structure defining the relation between the course and the profile as in the case of SMART-Learning.

XSLT can transform an XML document into another XML document according to present selection criteria. In SMART-Learning, these criteria (educational, of localization) can be associated to any element of the course (PS, PSe, media). Thus, a generic course, containing all the possibilities, will be transformed into a specific course thanks to an XSLT document which includes specificities of the learner profile (figure 4). In fact, the general transformation parameters contained in the generic XSLT document are transformed using the profile values.

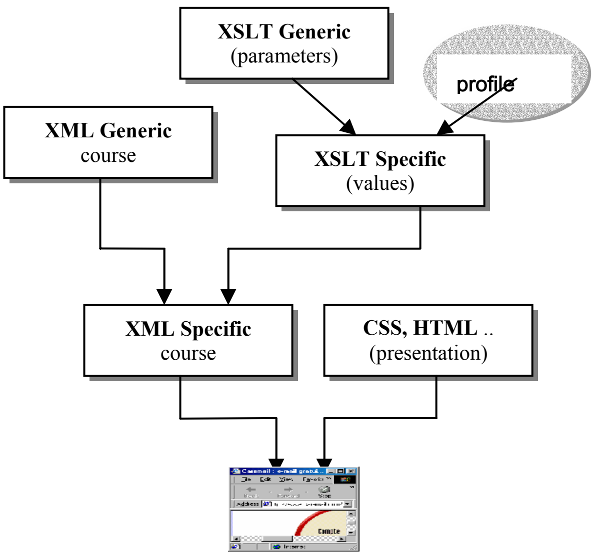

Figure 4: Successive transformations of a SMART-Learning course

Figure 4 also shows how is made the final transformation, using CSS and even XSLT to transform into HTML so that the course can be visualized on a Web browser.

4.5 The XML course transformation processes

This section details how the XML tools allow selecting a learner profile in order to prepare step by step the content that corresponds to a learner according to his profile.

A course or a part of it is represented by a pedagogical sequence. There will be only one generic XML document (see listing 1) to represent a PS, valid for all learner profiles(Engineer, technician, french, english ...). Thus, for each learner profile, it will be enough to apply the adequate XSLT transformation on this generic course.

Let's take the example of a simple course part:

P. XML generic course

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE EPS SYSTEM "course.dtd"
[
<-- media element reference -->
   <!ENTITY titrefr SYSTEM "titrefr.txt">
   <!ENTITY planfr1 SYSTEM "planfr1.txt">
            ---------------------------------------------
]>
<PSE id_PSE="ch1med2">
   <PSE_Obj_Pedag Val=" engineer+technician">
            <PSE_Language Val="french">
                        <Media type="text" url="" id_Style=""
                        niveau_Media="1">&titlefr;</Media>
                        --------------------------------------------
                        <Media type="text" url="" id_Style=""
                        niveau_Media="2">&planfr1;</Media
                        >
            </PSE_Language>
            <PSE_Language Val="english">
                        <Media type="text" url="" id_Style=""
                        niveau_Media="1">&titreen;</Media>
                        <Media type="text" url="" id_Style=""
                        niveau_Media="2">&planen1;</Media
                        >
                        ------------------------------------
            </PSE_Langue>
            </PSE_Obj_Pedag>
   <PSE_Obj_Pedag Val="technician">
            <PSE_Language Val="french">
            ---------------------------------------------
            </PSE_Language>
            <PSE_Language Val="english">
            ---------------------------------------------
            </PSE_Language>
   </PSE_Obj_Pedag>
</PSE>
```

Listing 1 : Generic XML course

Knowing that each learner has a given profile which is supposed to change constantly during all the learning process, it is impossible to predict all possible XSLT transformations that could be applied to the XML generic course. This led us to choose a solution with a generic

XSLT file (see listing 2) containing the parameters representing the profile.

Generic XSLT transformation

```
<xsl:transform
xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
version="1.0">

<xsl:variable name="PSE_Language" select="''"/>

<xsl:variable name="PSE_Obj_Pedag" select="''"/>

        <xsl:template match="/">
                <xsl:for-each select="PSE">
                <xsl:choose>
<-- instructions de transformation --------->
                        ---------------------------------
<xsl:when test="contains(@Val,$PSE_Obj_Pedag)">
                        ---------------------------------
                        </xsl:choose>
                </xsl:for-each>

        </xsl:template>
</xsl:transform>
```

Listing 2 : Generic XSLT transformation

Let's give the following values for a simplified profile:

Profile	
Pedagogical objective	Engineer
Language	French

Table 1 : Profile

Thus, the parameter setting of this generic XSLT by the profile elements will dynamically give an XSLT specific to this profile (see listing 3) containing the values corresponding to the profile(table 1):

Specific XSLT Transformation

```
<xsl:transform
xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
version="1.0">

<xsl:variable name="PSE_Language"
select="'french'"></xsl:variable>
<xsl:variable name="PSE_Obj_Pedag"
select="'engineer'"></xsl:variable>

        <xsl:template match="/">
                <xsl:for-each select="PSE">
                <xsl:choose>
<-- instructions de transformation --------->
                        ---------------------------------
<xsl:when test="contains(@Val,$PSE_Obj_Pedag)">
                        ---------------------------------
                        </xsl:choose>
                </xsl:for-each>
        </xsl:template>
</xsl:transform>
```

Listing 3 : Specific XSLT transformation

Thus, to generate the XML course specific to a profile, it is enough to apply to the XML generic course the XSLT transformation specific to this profile (see listing 4).

Specific XML course

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE PSE SYSTEM "course.dtd" [
        <!ENTITY titrefr SYSTEM "titrefr.txt">
        <!ENTITY planfr1 SYSTEM "planfr1.txt">
        ------------------------------------------------
]>
<PSE id_PSE="ch1med2">
  <PSE_Obj_Pedag Val=" engineer ">
        <PSE_Language Val="french">
        <Media type="text" url="" id_Style=""
niveau_Media="1">&titrefr;</Media>
        ----------------------------------------------
        <Media type="text" url="" id_Style=""
niveau_Media="2">&planfr1;</Media>
        ----------------------------------------------
        </PSE_Language>
        </PSE_Obj_Pedag>
  </PSE>
```

Listing 4 : Specific XML course

As the specific XML course is obtained, it is enough to apply on him an XSL or CSS stylesheet according to the wished visualization. Listings 5 and 6 show the use of an XSLT stylesheet that transforms the course into HTML incorporating a CSS stylesheet to be presented to the learner.

XSL transformation for the presentation

```
<xsl:transform
xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
version="1.0">
    <xsl:template match="/">
        <HTML>
            <head>
                <LINK REL="STYLESHEET"
TYPE="text/css" HREF="./course.css" TITLE=" smart
style "/>
            </head>
            <BODY>
                <xsl:for-each select="PSE">
            ---------------------------------------
                <xsl:if test="@type = 'text' and
@niveau_Media='0'">
            ----------------------------------------
                </xsl:for-each>
            </BODY>
        </HTML>
    </xsl:template>
</xsl:transform>
```

Listing 5 : XSL transformation for the presentation

```
External CSS for the presentation

*{background-image:url(..\Media\bg20.gif)},
.texte_niveau1{     font-size:20pt; color:blue;
                    border-style:double;
                    text-align:center
                    }
.texte_niveau2{     font-size:15pt;
                    color:black
                    }
.img_niveau3{       margin-left: 20
                    }
.img_niveau4{       margin-left: 45
                    }
```

Listing 6 : CSS for course presentation

XML and its tools allow thus, using a relatively simple representation, fitting the characteristics of a telelearning course and in particular the adaptative and structured courses of SMART-Learning

Set-in an interactive multimedia database of the French EEA association

Olivier BONNAUD[1], Yves DANTO[2],Christian GLAIZE[3], Jean-Paul LOUIS[4]

Abstract

In addition of the several virtual campus that are created in the world, the French EEA association composed of about one thousand members started the creation of a on-line data-base in the field of electrical and information engineering with the both goal to give an additional support for the students and to impulse the creation of new innovative pedagogical tools.

1. Introduction

In 2001, the French association of teachers and researchers in the field of electrical and information engineering, called "Club EEA" [1] gathered more than 1000 members and was structured as shown Figure 1. In addition of the executive board that includes the President, the General Secretary and the Treasurer, two main levels in the operational organization can be found. Thematic level that is constituted of four chapters gathering main domains (electronics / microelectronics / optoelectronics, signal processing, power electronics / power electrical engines, control automation.

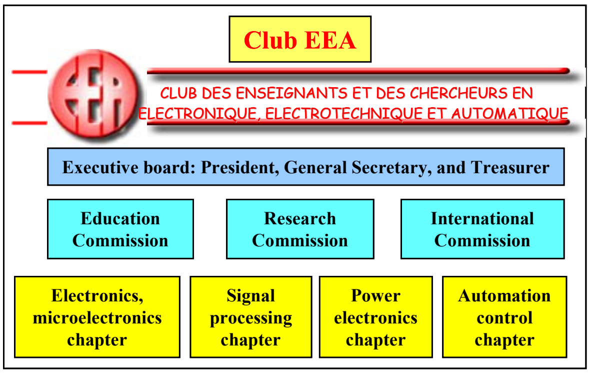

Figure 1: "Club EEA" Association structure. Two main levels in the operational organization: the scientific field chapters and the transversal commissions. The full board is constituted of the resident and secretary of chapters, presidents of commissions, and of the executive board.

1President of "Club EEA" Association, University of Rennes 1, Pôle CNFM de Rennes, CCMO, Campus de Beaulieu, 35042 Rennes Cedex, France University
2President of the Education Commission of "Club EEA" Association, University Bordeaux 1, Electrical Engineering Department, 351, cours de la Libération, 33405 Talence Cedex, France,
3 Responsible of Pilot Group of e-EEA Médiathèque, Laboratoire d'Électrotechnique de Montpellier - Université Montpellier II, CC079, Place Eugène Bataillon, 34095 Montpellier Cedex, France
7

The transversal level is composed of three commissions: academic's or education's, research's, and international's ones. From Education Commission, a specific group, called "Pilot Group" (PG) was created in order to set-in a database and new tools with the final goal to create a virtual campus. This was the result of an analysis of the evolution as well of the French Institutions in which some members are positioned, as International well-known institutions such as MIT, Stanford, etc. [2]. To improve the traditional presentations already available via Internet, we have decided at the level of the Education Commission to create a tool making easier the creation of new courses. This is the specificity of what we have called: "Médiathèque e-EEA™ " [3].

2. Reasons of such an approach

The fast increase of the new knowledge flow, the wide spectrum of knowledge, the evolution of the culture and the behavior of students lead to a permanent adaptation of our teaching approach.

It is clear that the video-image, Internet, and zapping, are new parameters to take into account to be attractive to students that are less and less excited by scientific studies.

In addition, more and more potential students can be interested to improve their knowledge without any live-lesson, but with some tools that give more than a book or a monograph, especially in the technology fields as in electronics, control automation, signal processing, electrical engineering, microelectronics, optoelectronics that constitute the main domains for which we are concerned. These domains are particularly adapted to dynamic presentations, schematic, and simulation approach [4]. Moreover, the pedagogical approach can be really different allowing as well classical French bottom-up approach as top-down one, as shown in Figure 2.

Indeed, the development of computer assisted education tools offers the possibilities to modify the classical teaching approach and maybe to make easier the harmonization in Europe of education in electrical and information engineering [5-6]. It is possible to begin the course on a system or application, and thanks to the permanent access to the links, to go back to basic and fundamental knowledge. In this situation the student understands or discovers the necessity to improve his fundamental knowledge and the course can be much more attractive; in fact it is generally appreciated by students. Figure 2 shows a sketch of the both approaches: bottom-up that corresponds to the usual education and top-down that is available in the new multimedia tools.

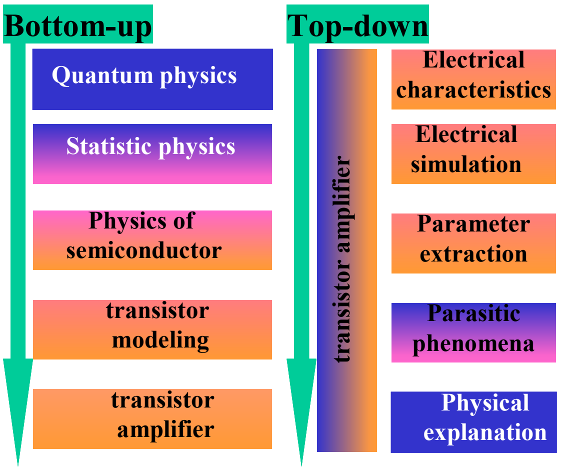

Fig. 2: Bottom-up and top-down approaches that are easier to set on with interactive tools (*After Bonnaud et al* [2]).

In such a context, we can admit that, alone, a teacher cannot easily modify and permanently improve his lessons, creates new interactive tools, new dynamic training, etc. The Club EEA is an organization establishing permanent links between its members and allows a common gathering of skills and resources that is today the need to highlight and valorize the individual approach. These documents are compiled in the Médiathèque e-EEA™" on-line available and reachable by everybody. To access to the associated site, the present address is: http://www.e-eea.org.

This behavior is a goal for our community, who considers that its contribution to the information world from its own skill and know-how in the knowledge world constitutes a main part of its mission. The diffusion of a part of its knowledge is the basement of university behavior in order to encourage contacts between people; this leads to an enhancement of the general knowledge and an increase of the knowledge need. At international level, an on-line Mediatheque e-EEA™ should encourage the cooperation between countries and should give access to new knowledge to undeveloped countries.

3. Principle

The Médiathèque e-EEA™ is an open on-line site giving access to teachers and students a set of scientific documents that gathers the pedagogical production of involved teachers. It is an exchange and diffusion tool with free access.

Copyright: The intellectual properties are the properties of the authors that keep the full rights. The Club EEA association diffuses the documents, and by this way, brings its notoriety.

The users are first the teachers that can judiciously use the on-line documents to built their own lessons but after signing a Charter". The students are the second type of users and can use this tool for learning and training as well in basic education as in life-long learning.

The documents are not, for a majority of them, in a first time, a self-consistent interactive course independently useable that needs a huge work (authors, software's, designers, etc..) that only one institution cannot produce easily. However, the Club EEA members constitute a huge potential of technical knowledge. Thus, the initial goal consists to produce scientific documents often resulting from traditional edited documents but with a few part, at least, of new information technologies in order to improve the information quality by the way of photographical illustrations, animations, interactive documents, integrated simulations, hypertext links, etc. Note that, some colleagues have already produced some interactive courses that can be immediately included in the Médiathèque e-EEA™, via links. That is the case of an interactive course on integrated microelectronic technology [4,7-8].

Following the advice of the PG, the scientific documents are generated and signed by their authors. After reviewing by the PG and selected colleagues who are member of adapted specialty chapter, an abstract is written in order to build a compact database easily consulted. Even if some books already exist in such or such field, this database can enlarge the spectrum.

This implies several effects:

- The various approaches in one specific field thanks to the contribution of several authors for which the sensitivity can be quite different,
- Heterogeneity of presentations, the authors using either some different animations or links. To minimize this heterogeneity, a coordinator chosen among the related authors has in charge a unified presentation in term of notations, symbols, et..,
- The concision of chapters that allows an involvement of numerous authors due to the minimization of their respective tasks,
- Only some compact modules can be selected in the whole document (or website) produced by colleagues, to be in agreement with copyrights or exclusivity.

4 Example of on-line tools

To give an idea of the beginning of this database, an example on the integrated microelectronic technology course, available on its own website [8] or from a link of the Médiathèque e-EEA™ site is presented in this part. Figure 3 shows an html page available on the web-site and in the English version that is in construction, the French one being achieved. Other foreign language versions are almost achieved, especially in Finish [9] and in Romanian [10].

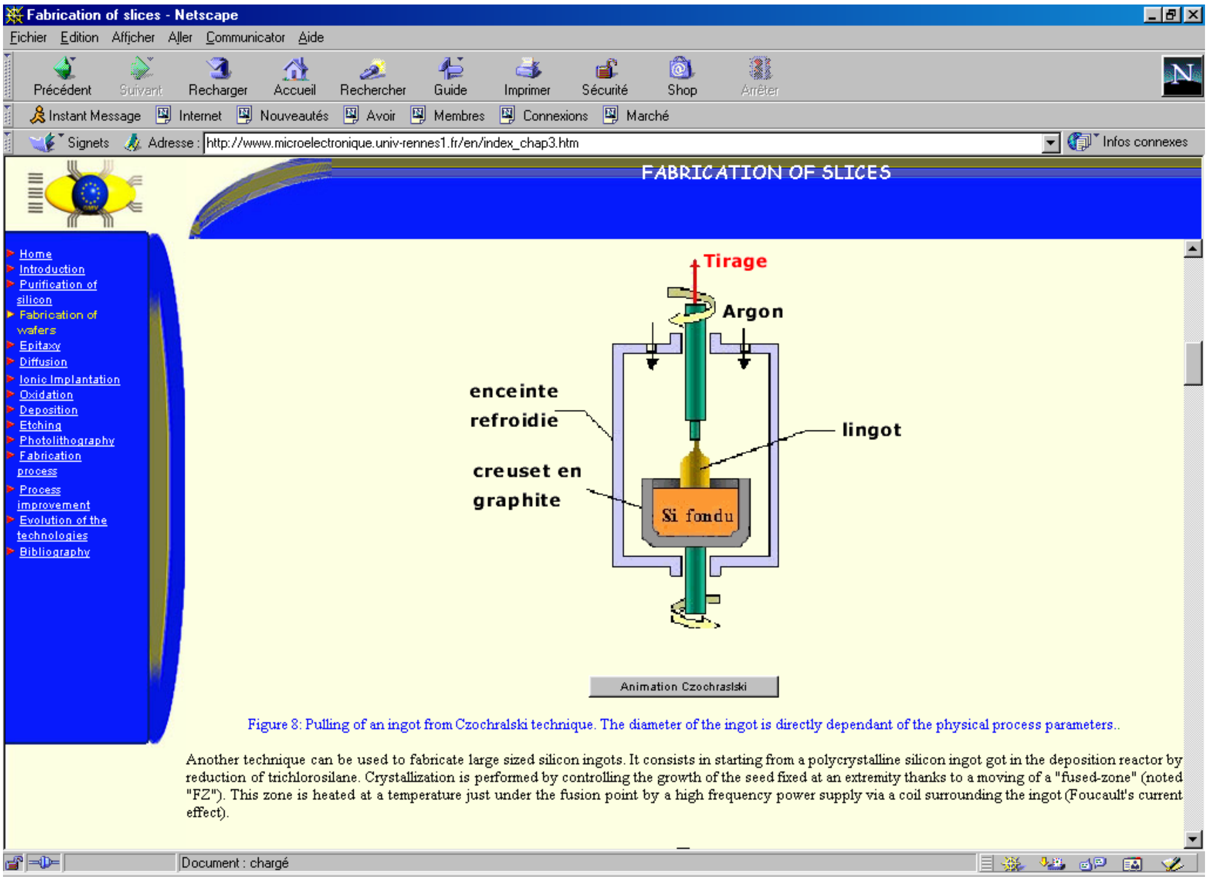

Fig. 3: Example of an html page of the integrated microelectronic technology course. This page corresponds to the English version of the document, which is in construction. The French, Finish and Romanian ones are almost achieved. Only, comments on figures are not yet translated in these last cases.

As shown on the figure 4, animations are included in the document that gives much more indications, especially in the field of technology for which a short animation describes much better an experimental technological step than a long text.

In this document, also simple simulations are available. Figure 4 gives an example of simulation that can be achieved to evaluate the growth rate of a thermal oxide. The user can change the data, and the simulation is performed through a Java applet, loaded in the personal computer or workstation of the user. In this case, the user saves some precious time of loading. Of course, the modeling is basic in this case to avoid too much long loading and calculation durations. The results are approximate but give a good idea of the basic phenomenon. As an example, the Grove’s model is used to simulate thermal oxidation in Figure 4.

Note that a lot of other examples can be given. Several colleagues have already set on the website of the Médiathèque e-EEA™ links to tools such as VHDL training, basic logic course, digital electronics, introduction to power electronics, electrical engine modeling, digital signal treatment, etc…[11]. In addition, the database can link to distance training developed by some colleagues. A good example is the Redwin long distance training developed in the frame of European collaboration [12] or a distance learning experience for IC test [13] set-up thanks to the French national committee for education in microelectronics (CNFM) [14].

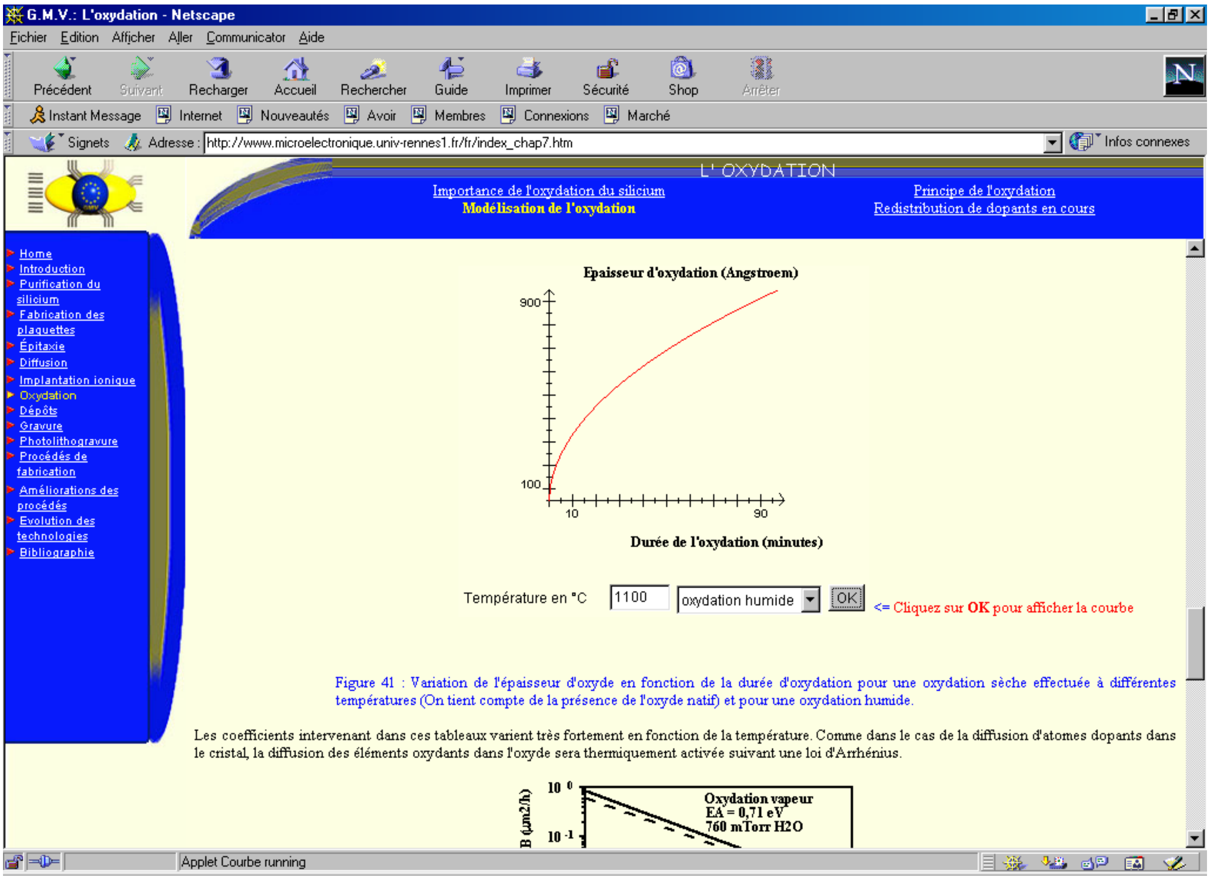

Fig. 4: Example of technological simulation included in the microelectronics module. The oxidation modeling is performed thanks to a Java applet loaded in the personal computer of the user. This procedure saves a lot of transfer time. The user has just to enter the data and activate the simulation. In this case, the modeling is simple to minimize the loading and transfer duration on the computer.

6 Conclusion

The Médiathèque e-EEA™ is potentially a huge tool able to spend knowledge as well to teachers as to students in the field of electrical and information engineering. It involves new educative technologies that allow making more attractive our fields to students and making much easier the learning of technological courses. The modern approach is in addition much more accepted by the students but also by teaching colleagues who can save a lot of time to prepare new courses in their own institutions.

This main objective is possible thanks to an active and well-organized structure built in the frame of teacher and researcher organization, the Club EEA. Diversity of approaches depending of different feelings of the scientific disciplines can enlarge the spectrum and enrich the global database. In its final form, this Médiathèque e-EEA™ should constitute a solid basement for a virtual campus.

Acknowledgments

The authors thanks all the members of the Pilot Group and all the colleagues who have contributed to set-in the database by loading their pedagogical products or establishing links to the website of Médiathèque e-EEA™.

K12 INITIATIVES: A PATH TO THE FUTURE OF CITZENSHIP

Janete Molnar [1], Edvaldo Valle [2], Melany M. Ciampi[3] and Claudio da Rocha Brito[4]

Abstract —*This work shows the political and educational efforts of a project for K-12 that one of the main goals consists in the enhancement of young people to choose carriers like engineering. The social dimensions of it are clearly leading to a deep change in that particular society showed by the very positive feedback. Everything has been conceived to make it particularly attractive to young students of K-12 mainly the name "Let's go folks!" The project has been developed and applied by the City Hall education coordination in a joint venture with Supportnet, a private enterprise with the support of COPEC – Council of Researches in Education and Sciences. The overall results of "Let's go folks!" are highly encouraging and it could be seen as a paradigm for the other Brazilian education public institutions.*

Index Terms — *paradigm, pedagogy, policy, qualification, teamwork, technological illiterate.*

INTRODUCTION

Lately less and less young people are choosing engineering as a career. There are some reasons for this, among which two of them appear as of high relevance as the fall of social status and the low level basic sciences teaching in high school.

Certainly this issue has generated many discussions in academic and scientific communities in Brazil and some practical actions at governmental level have took place. And among them there is one that is the object of this work. It is the initiative of São Vicente City Hall that has decided to implement special programs for K12 in public schools in the city.

In order to attract more students into engineering, which is so necessary for the development of a country, an innovative approach was taken at the K-12 public schools in São Vicente city. The project has been developed and applied by the City Hall education coordination in a joint venture with Supportnet, a private institution with the support of COPEC – Council of Researches in Education and Sciences.

The chosen name Let's go folks! Is a slogan that speaks the language of young people and the Fortress of knowledge is the special space created in the schools where the students can spend some hours of the week enjoying the good time of learning in a complete new way. It has been dimensioned to make the students to feel special, a space to hold their interest and to get them excited about new technologies, informatics and so on.

It started in February of 2002; it has been planned to serve 10 thousand students per year, including the qualification of teachers and technical staff.

The creation of a public University in the town is the next step that will be accomplished in a medium to long period of time, which is the city demand due to the enlargement of population and the new mentality of the new politicians presently in charge. A new policy era has started in the country inspired in the new Presidency that express the Brazilian population hue and cry for the betterment of its society. It is time for changes and deep changes in education in order to combat the technological illiteracy.

BRAZIL'S ENGINEERING HISTORY

Colonization of Brazil plus the insurance aspect of Portugal made the royal government to recognize the necessity of forming the national engineer and so becoming it of crucial importance. It was made always attending the evolution of French Schools of Engineering also in 1641 in Lisbon born the Artillery and Square Classes becoming in 1647 the Special Class of Fortification and Architecture. The Portuguese engineer Luiz Serrão Pimentel (1579-1613) managed the school and it is considered the starting point of Lusitanian-Brazilian engineering [02].

Engineering schools still keeps the European schools style obviously because of the great influence of its countries along the colonization process. The evolution of engineering in Brazil follows very close the world trends. From the construction of Fortifications through electrical engineer to what is called today Mechatronic engineering in the country has developed in according to the necessities of promoting its development always seeking for the best applications of sciences achievement to the local resources.

Through the time many huge proportions accomplishments can be seen, not only public buildings and houses but also practical applications of electricity like telegraphy, telephony and lighting. Electrical energy conquests that were applied in Europe and USA shows that similarly the insertion of electrical energy in Brazil happened in the same historical moment of industrial expansion and development of developed countries.

Since the Fortification Classes and Military Architecture founded in Bahia, in 1699 until more than 200 engineering schools of present time, engineering education has had a

history of success full of many conquests and accomplishments [03].

EDUCATION CONQUESTS THROUGH TIME

The Public Universities that raised in the many states of the country and that have worked very well for many years, made the country to achieve and built a solid reputation even abroad also creating generations of Brazilian scientists and educators [04]. These people fortunately have refused to accept the ominous and narrow-minded neo-liberal policies for education having started a fighting to keep up the achievements already gotten and actions that help to maintain and to enhance the researches in every field of science and technology [05].

For many years large discussions about national scientific and technological directions at national level took place and still take place in conferences, all communication medias like radio, TV and etc, despite it may seem to be a lonely fight once economical speculations seems to be more powerful with more sharp actions world wide.

Professionals and educators of every field of science and technology have been discussing the destiny of education in the country taking into account the historical moment of the world. Certainly some of these discussions have generated some practical actions at governmental level as a response to the society that see itself as the most interested part in the issue. In Brazil in engineering and technological fields the situation is very delicate. Although the proliferation of private universities all over the country expanding the number of 3rd grade students it does not assure the increase of students in engineering and technology areas. Looking through this perspective the K12 appears as one way to help students to develop skills to follow careers in these fields.

São Vicente City Hall management is one example of the new political mentality and so after some social conquests has decided to implement a special program for K12 in its public schools. Conscious of the importance of eradication of the so-called "technological illiterate" (that is now as important as the eradication of the "illiterate"), has been working hard to get the goal to enhance the number of students to choose the engineering and technology fields.

TECHNOLOGICAL EDUCATION: VALUABLE ASPECTS OF ITS INSERTION IN EDUCATION

Valuable workforce in a technology-based society of XXI century depends on an educational system that prepares students in mathematics, engineering and sciences. To accomplishment such task São Vicente City Hall is counting with the excellence of a national private enterprise located in the city, which is Supportnet that has been acting in the market for many years and that has a reputation of quality services and credibility. It is essentially the appliance of solutions for technological problems oriented to the clients/students necessities, in the several areas of knowledge.

Educational informatics in the development of students' cognitive potential is of great importance. The informatics knowledge is a powerful educational instrument to turn young people their own agents of learning process and in the building and acquisition of their knowledge; at last students more autonomous in the solving of problems using their logical - deductive reasoning in an effective way becoming them more capable to interact with people and the reality that surrounds them. Let's say that this is the technological literate citizen [06].

Technology high-speed advancement and globalization made essential the use of informatics in all human environments. The intelligent use of computers becomes effective when it is used in a way to make the student to explore her/his capabilities and to develop skills. It contributes to their further development and the seek for sustaining values, including a commitment with her/his own learning [07].

LET'S GO FOLKS! – A DESIGN STRATEGY FOR YOUTH

This special program is based in an integrated educational method using computers as the tools to increment the learning process aiming the betterment of fundamental education system, the K12.

Engineers, Pedagogues, Social Agents and others scientists and technicians involved with education have been working in the implementation and development of this project.

It encompasses top technologies with access to Internet and complete didactic material designed for this kind of proposal.

The project has been named "Let's go folks!" as a strategy to reach the young students. Another strategy of marketing to get the attention of them is the name of the labs, so called "Fortress of knowledge".

FORTRESS OF KNOWLEDGE – THE HISTORICAL ASPECT CONTRIBUTING TO THE STUDYING EFFECTIVENESS

Unfortunately, many K-12 students loose interest in subjects that are considered very difficult like mathematics, physics and others. The implementation of this new K-12 program aims essentially to generate the intellectual excitement among the students toward the acquisition of knowledge. The new approach with the computer as a powerful tool has showed to be effective to enhance the learning process.

It is a student-centered paradigm of education and with pedagogic proposal the Fortress of Knowledge is the special space created in the schools where the students can spend some hours of the week enjoying the good time of learning in a complete new way. It looks like the ancient fortresses that were built in the city in the XVI Century to protect it from the pirates and invaders. Nothing more charming! It contains in its space the computers around 20 (in each space) connected in a network, with Internet access.

The implementation of the program started in February of 2002; it has been dimensioned to serve 10 thousand students per year, including the qualification of teachers and technical staff for the next four years.

PROJECT BODY

Its physical infra structure contains 16 laboratories with 20 points of network each, in according to the international pattern EIA/TIA 568-A, where each lab contains one Rack with key and the local network active element (Switch 24 doors 10/100 MBITS).

The whole project is compounded by:

- 320 Celeron computers 800 MHZ/ Disk of 20GB and 128 MB RAM/ Colored monitor with 15"/ CD-Rom/ Stabilizer.
- Supply of 32 printers, 2 for each lab.
- Large band internet access

The laboratories dimensions are large enough to attend the necessities of the schools for present and they can be enlarged with the time and the new demands.

Internet access infra structure:

- The chosen technology for Internet access is the frame-Relay and 512Kbps speed.
- All labs have local and remote connection equipment (Switch, rotator and modem).

Supportnet offers a didactic material that has received special attention that provides the students all the necessary information for the correct use of computers.

PEDAGOGIC METHODS

Teaching Methodology:

- The proposal of teaching methodology in this program is based mostly in the interaction and real experience.
- The qualification is gotten by means of 25% of theory and 75% of practice [08].

The use of computer in education has been showing as an important agent in the promotion of closer and so important between adviser/instructor and pupil.

Evaluation Methodology is based on some methods, some orthodox and some non-orthodox. It depends on the teacher and they can be [09]:

- Presentation of works developed with the use of the computer developed during the course.
- Frequency of classes' presence, at least 75%.
- Lectures and practical exercises.
- At the end of the course the students have a test to evaluate the knowledge acquisition based in a minimum quantity required to be approved and get the certificate [10].

TIME STRATEGY

In order to accomplish the task the students have a schedule that has:

- 60 hours of Office package (Windows, Word, Excel and Internet);
- Professional certificate for 8^{th} year of Fundamental School;
- 45 hours of basic Windows, Word, Excel and Internet form the 5^{th} to the 7^{th} years of Fundamental School.

TEACHERS QUALIFICATION

Qualified teachers with knowledge in informatics are so important as good technical staff [11].

Teachers and students have a schedule to attend the necessary courses to improve their knowledge and also to help the students that will be as well transformed by the use of this new technology.

To get this goal the teachers have:

- 08 hours of typing;
- 80 hours of Office (Windows, Word, Excel, Power Point and Internet);
- 40 hours of informatics in Education.

Teachers and students have full time technical and pedagogical assistance and support of the staff for anything at all.

INNOVATIVE APPROACH

Presently one of the most important aspects to be taken into account is the challenge to make the program more attractive for the students so it should have a kind of content that is equally cultural and appealing. Bellow there are some examples of extra available topics plus the program content:

- Availability of Internet access;
- Virtual Bulletin;
- Web mail;
- *Let's go folks!* Journal;
- Best students of the month;
- Download areas (tutorials)
- Educational games;
- Chat;
- Know your City!
- Test your knowledge;
- Virtual Library;
- Internet Challenges;
- News;

These are some material available that are constantly updated to help students to develop a framework for understanding effective knowledge and cultural achievements [12].

ACCOMPLISHMENTS

The most important objective is to provide the public school students the possibility to develop the skills to choose careers in engineering and technology fields. It is done by:

- Training and qualification of public schools teachers in technology education and pedagogic design;
- To promote the betterment of its citizens qualifying them through the informatics specialization.

Social dimensions of this program for sure exceed the school borders and its first goal.

CONCLUSIONS

The history shows visibly that engineering in Brazil has started with the military engineering, which military actions at that time, in the country were basically the construction of fortifications and the seek for solutions of defense and attack evolving to what is today the civil engineer. Since its origin in Brazil, engineering has evolved altogether world's trends.

Presently Brazil has been facing the challenge of managing the effects of such rapid science and technology development achievements combating the technological illiteracy in order to provide its people a better quality of life. It is a fight for surviving the environmental problems, the wild economic war between the big enterprises among others. Problems that will become worse for developing countries in a near future if they do not find a way to over come the inner problems and start to build a true nation for its citizens.

The overall results of "Let's go folks!" project conceived and implemented in São Vicente public schools have got very good results so far and the students are very pleased with their performance and the feed back has been very positive.

The implementation of the project has been so good that it is going to be amplified to the qualification of poor communities citizens of the city.

SIMPLE MATHEMATICAL MODELS WITH EXCEL

Traugott H. Schelker

Abstract — Maybe twenty or thirty years ago only physicists and engineers had any use for mathematical models. Today the situation has totally changed. Mathematical models have important applications in biology, medicine, economics, geography, psychology and many other disciplines. So a basi c understanding of mathematical modeling will be of benefit for everybody. In this workshop I will present some simple mathematical models using the program Excel. The aim is to show and develop simple, but typical and important examples of mathematical models. The participants will learn properties, possibilities and also limits of mathematical models. We will prepare and demonstrate a series of famous classical models and develop a model on our own. We will use only simple numerical methods with the Excel program. For this reason no further knowledge of mathematics, differential- or difference equations is required!

1. INTRODUCTION

"Mathematical models are almost as beautiful as models on the catwalk of a fashion house...!"

The most spectacular successes of mathematics in the last century have been in physical sciences. But over the last decades, mathematics have broken out into a whole new domain of applications in many different fields, social sciences, biology, medicine, agriculture, economy and others. In almost all fields of human endeavor mathematical tools became important. Today mathematical techniques and models play an important role in planning, decision making and also for prognosis. Without mathematical models we were left to manipulate real systems in order to understand the relationship of cause and effect. Manipulate real systems is often difficult, maybe impossible or too expensive. It may be possible for cars, but social and ecological systems are much more complicated! For these reasons mathematical models are now widely accepted as an appropriate tool for describing processes and matching them to our ideas and theories.

Furthermore modeling processes of dynamical systems, today have become a real possibility for each college student. Even without a long and significant preparation in mathematics, differential equations or computer programming, it is possible to prepare and study at least the main effects of simple models. Many programs exist, like Stella, Modus, Simulink or Mathematica etc., which allow to build such models. An easy and well known tool for studying simple mathematical models is the use of the Excel program.

The aim of this workshop is to give the participants an idea and appreciation of how simple mathematical models can be formulated, solved and applied. The main aspect is to show that simple ways of demonstrating and illustrating such models exist, without deeper knowledge of the theory of differential- and difference equations. I'm convinced it is more important to provide our students with an appreciation of mathematics and show them the important role of the discipline instead of frustrating students with an over emphasis of mathematical rigor!

In this workshop, we will use the Excel program to demonstrate a series of simple mathematical models. Excel is well known and most students have access to this program. And: our specific aim is to show that simple models can be prepared, studied and numerically solved without complicated special programs.

2. MATHEMATICAL MODELS: ITS ROLE AND LIMITATIONS

Mathematical modeling means the process of translating a real situation or problem from its original context into a mathematical description, called a model.

After that the mathematical model has to be solved and the results must be translated back into the original context.
We must emphasis the keyword "translation". The mathematical model is not the real situation, it's only a description in mathematical terms of the real situation.
Based on the results of the model we draw conclusions and maybe provide predictions about the events in the real situation. But then these predictions and conclusions have to be tested and compared to real events and then may lead to acceptance or falsification of the model or normally to its revision. So modeling in reality is a never ending process. We prepare, build, revise, build a new model, compare, revise and change it again. In any case, the model remains a partial view or description of the real situation. The model is not the real object, it's only an simplified image of the real thing! [4]

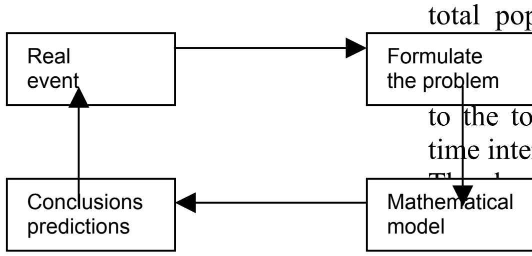

FIGURE 1
THE PROCESS OF MODELING

Some important components of the modeling process:

- Formulate the mathematical problem
- Solve the problem
- Interpret the solution
- Validate the model
- Explain, predict consequences
- Revise the model

3. HISTORICAL MATHEMATICAL MODELS

We start with some famous historical mathematical models, which played an important role in the history of sciences.

3.1 Malthusian population model

In 1798 Thomas Malthus, the famous American economist wrote the "Essay on the Principle of Population". At that time the industrial revolution and the related scientific discoveries caused a boom in the European population. So Malthus wrote like a prophet of doom. His essay with the phrase "Struggle for existence" probably influenced Darwin's theory about "natural selection for evolution". In fact Malthus formulated the first population model in history [1].
Definitions:

N = N(t) denotes the country's total population at time t
t = time in years
Δt = a small time interval
dN/dt = growth rate
a,b,c = parameters of proportionality

His assumptions:
For a short interval of time, say dt, Malthus assumed that both, birth- and death rate are proportional to the total population size and to the time interval. Or ... he considered the rate of growth of the ...n for a short time interval as proportional to the total population size and proportional to the time interval.
... formulated the differential equations:

birth rate = $a \cdot N \cdot \Delta t$
death rate = $b \cdot N \cdot \Delta t$
growth rate = $a \cdot N \cdot \Delta t - b \cdot N \cdot \Delta t = (a \cdot N - b \cdot N)\, \Delta t = c \cdot N \cdot \Delta t$

Taking the limit $\Delta t \rightarrow 0$ this equation leads to the differential equation:

$dN/dt = c \cdot N$
or $dN = c \cdot N \cdot dt$

This simple separable differential equation has the well known solution $N = N_0 \cdot e^{c \cdot t}$, where N_0 represents the population size at the beginning t = 0. As we will see, the behavior of the population depends very much on the constant c. We get exponential growth for c > 0, exponential decay for c < 0 and a constant population for c = 0.

Instead of solving this differential equation, we consider it as a difference equation and solve it numerically with an Excel sheet
Remark: In our equations we use the symbol dt although our calculations are based on a small discrete interval Δt

See model1

Malthus also considered food and land resources. He believed these resources would grow only linearly and so feared a human catastrophe in the future!
For the time period between 1500 and 1850 the real population growth in the USA reflects more or less the Malthusian model. Later on the errors of the model increase up to more than 30% and so the model is of little use! Malthus's model stands for unlimited growth ($c>0$) for all future time. And of course, this is very unlikely to occur, since there are many different limitations of growth. For these reasons, his model is not realistic for most situations.

3.2 Verhulst's population model

In 1845 Verhulst proposed a modification of the population model. He introduced a "crowding effect" for increasing populations. The assumption is, that the growth rate decreases when the total population size becomes too large for a given territory. This consideration reflects a certain "crowding effect". For the Verhulst's model there was a remarkable correlation between predicted population in the USA before 1900 and observed data.
Definitions:

N = the total population size
dt = a short time interval
a, b = two parameters of proportionality

Assumptions:
(1) The growth rate of the population for a short interval of time is again considered as proportional to the total population size, like in Malthus's model.
.
(2) But then the growth rate decreases when the population size becomes increasingly large. As a measure for large populations he used the product N^2
Thus he formulated the differential equations:

$dN = a \cdot N \cdot dt$
$dN = - b \cdot N^2 \cdot dt$ or finally
$dN = (a \cdot N – b \cdot N^2)\ dt$

This first order differential equation is not linear, because of the term N^2 , but it can be solved by a simple transformation. It results the famous formula of "sigmoid growth" or the so called "logistic growth". Again, instead of solving this differential equation analytically, we consider a numerical solution of the difference equation by Excel.

See model2

3.3 Mitcherlich's model

In the year 1909 Mitscherlich found out by experimenting with invitro cultures that production as a function of fertilizer does not increase unrestricted.
Assumptions: This fact urged him to consider the growth rate of production as proportional to the difference of production and a maximum possible production level. Mitscherlich also assumed, that there is an upper limit, say M to the production which can be sustained [2].
Definitions:

P = the actual production level of a plant for a certain area
M = maximum possible production level for this plant
a = factor of proportionality

His assumptions lead to the following differential equation:

$dP/dt = a \cdot (M – P)$
or $dP = a \cdot (M – P)\ dt$

For a numerical solution of the difference equation:
See model3

3.4 The Gompertz growth

This famous model has been introduced by Gompertz in 1825 for calculations of life assurances. After 1940 the model has been applied also as a basis for the extinction of animal populations in ecology and for the growth of tumors in medicine. The Gompertz growth is similar to the logistic growth and is encountered also in the study of growth of revenue in the sale of a commercial product.
We consider a closed two compartment model of plant growth [5].

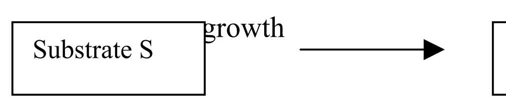

FIGURE 2
A two compartment model for growth

Definitions:

W = total dry weight of a plant or a substance in a growth process
S = substrate
dt = short time interval

a = parameter of proportionality of growth

c = a parameter describing the decay in the specific growth rate

Assumptions:

(1) The Gompertz growth can be derived by assuming that the substrate of the plant is not limiting the plant growth. So the growth machinery is always saturated with substrate. The growth rate is then again proportional to the dry weight

$dW/dt = a \cdot W$

(2) But we assume that the effectiveness of growth decays with time. This decay may be considered as due to degradation of enzymes. So the specific growth rate parameter a is no longer constant, but is itself governed by

$da/dt = - c \cdot a$ where c is a parameter, describing the decay in the specific growth rate.

We finally get:

$dW = a \cdot W \cdot dt$

$da = - c \cdot a \cdot dt$

These equations could easily be integrated, but we solve them again numerically by Excel.

See model4

3.5 Systems of linear differential equations

In biological systems as well as in whole populations there are usually two or more functions of time (variables) which interact with each other. So we get systems of differential equations. Let's consider the disintegration of an organic substance in two steps.

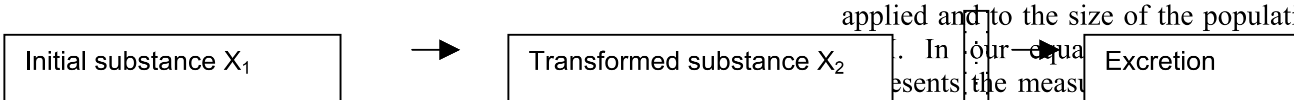

FIGURE 3
DISINTEGRATION OF AN ORGANIC SUBSTANCE

The original substance x_1 is first changed by enzymes in a transport form, called x_2. This second form of the substance finally is excreted through the cell membrane. The enzymatic reactions and elimination are considered as first order chemical reactions and so we assume that the rates of transformation are proportional to the quantities.

Definitions:

x_1 = original substance

x_2 = the substance transformed by enzymes, finally excreted

Assumptions:

(1) The rate of change is considered as proportional to the quantity x_1. The first equation expresses the disintegration of the original substance, which is transformed with the rate $k_1 \cdot x_1$ in the transport form x_2

$dx_1 = - k_1 \cdot x_1 \cdot dt$

(2) The transport form x_2 is created with the rate $k_1 x_1$ and excreted with the rate $k_2 x_2$

$dx_2 = (k_1 \cdot x_1 \cdot - k_2 \cdot x_2)\ dt$

The two linked equations describe the disintegration of an organic substance in two steps.

Example "Insecticide"

An other example of these kind of equations is found in the effectiveness of an insecticide. Here for instance we get a system of two non-linear linked equations.

Definitions:

I = quantity of insecticide used

P = population size of insects

dt = small interval of time

a, b, c = parameters of proportionality

Assumptions:

(1) The decrease of insecticide (disintegration) is proportional to the applied quantity of insecticide.
(2) The insecticide causes an increase of the death rate of an exponentially growing population of insects a·P, which is proportional to the amount of insecticide applied and to the size of the population ·- . In our equa t P·I esents the measu ce of insecticide..

$dI = - c \cdot I \cdot dt$

$dP = (a \cdot P \cdot - b \cdot P \cdot I)dt$

For a numerical solution of the example:

See model5

3.6 Population dynamics of salmons

Here we consider a simple model of Richter from 1974 [2]. This model has been applied on populations of salmons in the Pacific Ocean. We consider the cycle:

E----L----Y----A

Definitions:

E = eggs, L = larva, Y = young fish, A = adult fish

a, b = parameters of proportionality

p_1, p_2, p_3 = probabilities of survive

e = mean of the number of eggs per fish

Assumptions:
For many species of fish and for salmon as well, the larva will be eaten not only by predatory fish, but also by the adult fish of the same species. Therefore it is obvious to formulate the equation:

$$dL = (-a \cdot L - b \cdot L \cdot) \cdot dt$$

In this equation the first term is the death rate of larva because of other predatory fish. The second term is the prey rate of adult fish, which is indicated as a product of larva and adult fish (cannibalism!). Furthermore the number of larva L_0 at the beginning is equal to

Larva: $L_0 = e \cdot p_1 \cdot A$ where $\cdot p_1$= probability that larva hatch out,

A = number of adult fish

Young fish at time t: $Y_t = p_2\ L_t$ where p_2 = probability of survive of the larva

Adult fish at time t+1: $A_{t+1} = p_3\ Y_{t+1}$

We get a complicated dynamical behavior. Depending on the values of the variables, we even get a dynamical chaos!

For an illustration of the numerical solution :

See model6

3.7 Interacting species: Cassical Lotka and Volterra systems

The Italian biologist d'Ancona discovered in 1925 a drastic increase of predatory fish in the Adriatic Sea, as a consequence of limitations for fishing through World War I. His publication animated Volterra and at the same time Lotka in the USA to study ecological models. In 1925 Lotka published a famous book "Elements of physical Biology" with studies of different models. All these models are relatively simple and for this reason describe ecological systems insufficiently. Nevertheless they are still useful as a base in the understanding of the complex dynamics of biological systems.

As an illustration of an idealized case of such a model of interacting species, we consider foxes and rabbits living in a certain area, which has an abundance of food for the rabbits. On the other hand the foxes depend on eating the rabbits for their food. Let us define the prey and the predator populations in mathematical terms as X and Y. The two populations interact with each other.

Definitions:

x = predator population

y = prey population

a, b, c, d = parameters of proportionality

We can formulate the following assumptions:

(1) In the absence of predators, prey would grow unlimited, according to $dx/dt = a\ x$
(2) In the absence of prey, predators would decrease and finally die out, according to $dy/dt = -b\ y$
(3) The interaction of the two species we express by the product term $x \cdot y$, which is a measure for the interaction of the species. $x \cdot y$ is positive for predators and negative for prey.

So we get the model:

$$dx = (a \cdot x - b \cdot x \cdot y \cdot) \cdot dt \qquad x = \text{prey}$$

$$dy = (-c \cdot y + d \cdot x \cdot y \cdot) \cdot dt \qquad y = \text{predators}$$

For an illustration of the interacting of the two populations: See model7

3.8 Tourism and environment

Let's assume that a certain region is very famous for its beautiful natural environment. For this reason, the region attracts a lot of tourists. But the tourists on the other hand stress and pollute the environment. These effects reduce the attractiveness of the area and cause a reduction of tourism as a consequence and feed back effect.

But, of course a natural environment has the ability of self renewing its resources up to its maximum capacity.

Furthermore advertising influences and probably increases the number of tourists under the condition, that the environment is still attractive.

We could formulate the following system [3]:

Definitions:

T = number of tourists

E = conditions of the environment

a, b, c, d = parameters of proportionality

Assumptions:

(1) The attractiveness of the region depends on the conditions of the environment and can be enforced by advertising b·E
(2) The tourist stream is proportional to this attractiveness and this increases the tourist population
(3) The number of tourists is reduced by leaving tourists
(4) The strength of the environment by tourists depend on the number of tourists and also on the conditions of the environment and is for this reason proportional to the product T·E with a specific parameter d.
(5) Without future tourism a stressed environment would renew itself after a certain time up to its maximum capacity with a specific parameter c of regeneration

We could formulate the following equations:

dT = (-a·T + b·E·)·dt T = tourists

dE = (c·E·(M-E) - d·T·E·)·dt E = environment

For the numerical solution :

See model8

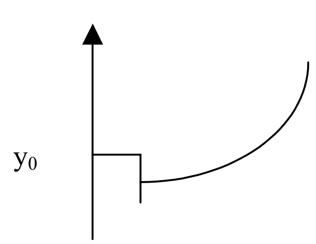
Appendix

"The method of Euler"

We can solve many differential equations created by such kind of models on the computer, using approximation techniques. The most simple of these techniques is the so called Euler's method. This method is based on a linear approximation using tangent lines.

To explain, let y' = f(t,y) a differential equation with initial condition $y = y_0$ when t = 0, that is at the beginning.

This means of course, that the solution of this equation is known only at the initial point (t_0,y_0) but that the derivative is known for all points (t,y) as shown in the figure.



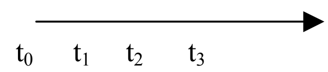


FIGURE 4
Euler's method

We consider now a time sequence t_0, t_1, t_2, t_3. Then the successive unknown values y_1,y_2,y_3 can be approximated by Euler's method, using tangent segments

$$\frac{y_1 - y_0}{t_1 - t_0} = f(t_0, y_0)$$

where $t_1 - t_0 = \Delta t$

$$y_1 - y_0 = f(t_0, y_0) \cdot \Delta t$$

$$y_1 = y_0 + y'(t_0) \cdot \Delta t$$

$$y_2 = y_1 + y'(t_1) \cdot \Delta t$$

and so on

$$y_{n+1} = y_n + y'(t_n) \cdot \Delta t$$

In this formulas, f(t,y) always represents the differential equation.

By using such numerical methods, we don't get exact values of the solution, because of all the small errors in the discrete time interval. But for the modeling of dynamical processes the exact values normally are not of high interest, but the typical course and development of the curves and their conditions.

The approximated values could be improved by using other approximation techniques in stead of the simple Euler method. For instance we could use the improved Euler-Cauchy method, the method of Heun or method of Runge-Kutta.

DISTANCE LEARNING CHALLENGING PRESENT COMPUTER ENGINEERING PROGRAM

Alexandre Botari [1], Melany M. Ciampi[2] and Claudio da Rocha Brito[3]

Abstract — *This work shows one proposal that is basically the adoption of an online course in the curriculum of one of a traditional Computer Engineering Course of under graduation level. The course is Digital Systems and with its success another course may be introduced, the Communication Systems. It is a very simple process where the students have available the course with all the synchronous and asynchronous tools existent in the Institution. Through Internet it is possible to access the whole content of the course in individual modules and in sequence. The modules count with introductory elements, theory, and development through examples, interactive simulations and exercises. In a large country like Brazil, Distance Learning, is not only leaning as an alternative for the traditional teaching, but principally, as a need to provide quality education for a growing demand in a land geographically disperse.*

Index Terms — *Asynchronous, modules, synchronous, team work, tutorial, web-based education.*

INTRODUCTION

At under graduation level, distance learning faces some problems of partner-cultural character that represent obstacles more difficulties to be overcome. Educational and pedagogic models consecrated in Brazilian universities, above all in the private institutions of superior education, suffer a strong influence of the secondary school teaching way that education is centered in teacher's illustration and the pedagogic model is based on the European model of the century XIX, which is basically established on present and expositive classes. This reality is constantly fed by the academic-administrative structure that approaches of the secondary reality with graduation courses offered all together in blocks, or packages, with little or any academic mobility, that should be the gist of the university academy.

However, such reality has been modified and the Distance Education cannot and it should have preponderant role in the transformation for a modern educational paradigm.

This work consists in the description of an innovative engineering education approach, which is basically the introduction in a traditional engineering program of one course a hundred percent taught remotely.

OTHER ALTERNATIVE TO INCREMENT ENGINEERING EDUCATION

The proposal consists in the insertion, in a first moment, of Digital Systems course taught remotely and later with the introduction of Communication Systems course [1-3] in a Computer Engineering Program totally ministered in a traditional way They are both a hundred percent at distance, with practically a hundred percent of their content ministered remotely too [4].

For such, the content of the course has been adapted to be showed in individual modules, settling down among them a logical-progressive sequence or based on punctual subjects (topics).

The content of the existent Engineering Programs count with the following content, (basically) [5]:

- Important Preliminary Concepts: general aspects of the chronology of communication systems;
- Theory notions of the information: definition of Information, Message, and Sign;
- Communication Channels: phone channel, optic fiber, satellite, channel capacity, general vision of the systems of analogical communications and type;
- Usual Definitions of band width; concept of Basic Band; types of Communications Channels;
- Technical of Transmission of Analogical Signs for Analogical Carriers: General vision of the Modulation Systems in Width, Angle and Phase, Modulation AM;
- Ghastly Effects of Modulation AM; Temporary effects of the Modulation AM; Percentage of Modulation: Positive, Negative and Total; Efficiency of Modulation;
- The Problem of Over modulation; Modulation SSB and VSB; Modulation in Angle: in phase and in frequency;
- Concept of Lineal Modulation;
- Considerations about Distribution of Potency in the Spectrum of a Signal FM: Functions of Bessel; The rule of Carson; Graphic form of visualization of the difference between AM and FM; Comparison between AM and FM; More important methods of Generation and Detection FM: PLL, FM Stereo;
- Basic Beginnings of Antennas: Polarization, Diagrams of Radiation; Gain; Resistance of Radiation; Width of Bunch;

[3] Claudio da Rocha Brito, Supportnet School of Technology, Av. Dr. Epitácio Pessoa, 248 - 33, 11.045-300, Santos, SP, Brazil, cdrbrito@supnet.com.br

- Introduction to the Usual Systems Communications: the. Phone Systems: The Evolution of the Telephone; Beginning of Operation;
- Telephones Cellular: main concepts; PX, PAX, PBX, PABX; Phone calls Local/Trunk; notions of cellular telephony b;
- Systems of Television: Initial concepts: square, Field, Persistence and Gleam, Resolution; The sign of Composed Video: synchronism H and V; equalization; Correction Gamma; Diagram in blocks of a TVC. General vision of NTSC, PAL Systems and EVAPORATE;
- Important initial concepts in digital transmission: synchronism types; acting calculation; systems CDMA4 - Communication for optic fibers;
- Types of fibers; propagation manners; characteristics of Transmission; examples of systems;
- Systems of Communication through Satellite Systems geostationary and of lower orbit;
- Transponder; Receiving stations; examples of connections;
- Basic Beginnings of Television Digital Differences of the analogical system; the digital code of the sign of Composed video. Diagram of the receiver; examples of systems;
- Codes brokers block Codes, recurrent and convolutions; interlacing; comparison of acting of coded systems and not coded;
- Notions of Digital Processing of Signs digital Sequences; transformed Z, decimation and interpolation; digital filters;
- Study of the Transformed of Fourier and its properties: linearity, areas in the domains t and f, duality, scale changes in t and f, translations in t and f, differentiation and integration, convolutions, correlation in the time and energy, ghastly density of energy. Functions of crossed correlation and of self-correlation for potency signs, ghastly density of potency, calculation examples;
- Behavior asymptotic of pulses. Pass-low filters without distortion. Representations of signs pass-strip, for components in squaring and for width-and-phase, wrapper; filters pass-strip without distortion. Relationship among them transformed of Laplace and of Fourier;
- Modulation: need to modulate and modulation types. Lineal or amplitude modulation. AM detection for wrapper. Modulators and detecting;
- Effects of synchronism lack. VSB, filters vestiges. Descriptions of TV system white-and-black and color. Examples of use of DSB and SSB;
- Exponential Modulation: FM and PM. Busy bands; tonal modulation, with one and two tones, spectra, phasor diagrams;
- Effects of no-linearity; generation methods and detection of FM. Analysis of PLL. Interference effects in the modulations AM, FM and PM; comparisons;
- Effect of the message spectrum;
- Representations of strip noise narrows: for components in squaring and wrapper-and-phase;
- Noise Effects in the lineal modulation; effect threshold;
- Noise in the exponential modulation. Effect threshold in FM; extension of the threshold.

PROGRAM PECULIARITIES

In order to accomplish the effective implementation of this distance-learning course the students have all the existent computational tool of the Institution (Teleconference, Chat, e-mail, etc.) available, besides a tutorial through the page of the course in the link of the course in the portal of the Institution.

Through Internet, interactive examples and simulations have been showing as powerful tools for the teaching of the Communication Systems course. The sequence of the course is showed through modules that count with introductory elements, theory, development through examples, interactive simulations and exercises for delivery (everything available on-line and off-line through "downloads" and e-mail).

The software has been conceived in Java language. The students of the Communication Systems should create their own links associated to the main Link of the Computer Engineering Department.

To concept its sites studies begins in-group with the aid of monitors of Computer course of Computer Sciences Program using basic tools as Microsoft Front Page Express that is an editor in HTML language. The easiness of the use of its resources and the tutorial of the package allows a fast development of the students to the step that they get familiarized with the tools of Distance Learning.

Starting from certain point, after an evaluation it is very possible, to abolish the presence in class room, just limiting to monthly encounters with the monitors and teachers of the course for the evaluation and a correct feedback of the program [6].

Tutorial counts with synchronous and asynchronous resources offers the opportunity, so much for the monitors' students (of advanced years of the course) as for the students of the course. The subjects guided by the students of the course are under responsibility of the monitors, so that when they have to face subjects that are besides their knowledge, they go to the responsible teacher of the course that monitors and supervises the whole change of information [7-9].

Meetings that can be scheduled and/or sporadic are then combined among monitors, students and the teacher of the discipline, in order to accompany the pedagogic progress of the experience, once it not only a change of the communication means, but it is about a whole paradigm change, accompanied, evidently for the respective psycho-pedagogic impacts [10].

Table 1: Examples of the modules of teaching at Distance of the Communication Systems course, time of duration and used Electronic Means.

Subject of the module	Time foreseen	Exercises	Computer Tools.
Notions of theory of the information	2h30min	5 for delivery	Internet Explorer, Acrobat Reader, Outlook Express
Convolutions	2h30min	10 on line	Internet Explorer, Acrobat Reader, Outlook Express e Chat
Discussion	50 min	-	Chat
Need to modulate and types of modulation	2h30min	5 for delivery	Internet Explorer, Acrobat Reader, Outlook Express
Noise in the exponential modulation	2h30min	-	Teleconference
Discussion	50min	-	Chat

Communication Systems modules of the course (table 1, shows some examples of modules), have been divided so that it is possible the necessary time for the approach of the subject, completely, and it can't exceed week time determined for the hourly load of the course.

Inside of the program of availability of the modules of the course have made use of Hypermedia, with the support of videos, tables, photos and some simulations as support to the theory.

Tutorial indicates it is a powerful tool in the elimination of doubts, not only in the use of the software, as well as for the resolution of the own suggested problems, through links of help.

Electronic mail shows to be the most used electronic way to remove doubts as well as for the shipping of answers of the proposed problems.

Monitors team interfaces the communication between the educational of the course and the students, in the resolution of proposed problems and also in the elimination of doubts, having, however, the educational supervision in all the correspondents communications and received through the protocols generated at once of the shipping and of the greeting of the correspondences [11].

Evaluation of academic use can be made in presence classes with the application of individual tests and in-group tends. The score can be pondered by the remote participation of the students in case of a smooth implementation to avoid radical prejudice.

FUTURE ACHIEVEMENTS

The proposal intends to increment with an evaluation totally remote instead of a written questionnaire filled in class. The goal is to make it more interesting for the students. [12-14].

Students should answer to questionnaire about Communication Systems course, in which they could express their opinions about the methodology and pedagogic aspects, as well as regarding the computational tools available in the Institution for this unusual experience of Distance Education in a personal program. Programmed meetings with the students and monitors are part of the implementation of this system they should happen once a month, with the objective of evaluating the progress and to motivate the academics to the self-discipline in the study remotely ministered. These scheduled assisted meetings should happen also with the purpose of illuminating persistent doubts and/or for the resolution of proposed problems of larger level of difficulty.

CONCLUSION

This Innovative proposal is an opportunity to cultivate and grow the quality of engineer of this century.

The presented proposal is especially based in the modern paradigm that presupposes the need of a growing and incessant autonomy leading the student self-determination and responsibility in the construction of their knowledge. Some premises of the program are student commitment in dedicating certain number of week hours to study through diversified available computational tools.

The main preponderant factor that can be mentioned is that the psychological factor of "inhibition" doesn't exist with any physical presence, what propitiates a larger frankness in answering the questions and the possibility of more interactivity.

This proposal suggests a new " format " to the orthodox educational methods, since it presupposes the use of methodologies consecrated secularly, such as called them seminars, for example, with derivations and innovative aspects when inserting in this the whole available technological tools in the institution, as well as the insert of more flexible and modernized concepts to the usual proposals. Collaboration between monitors and students shows to be a powerful way of helping students to be more effective learners and help staff to be more effective teachers.

The accomplishment of the project for now presented demands a great commitment of the faculty, once this, in educator's exercise, will provide a fomentation atmosphere to the research, motivating the necessary deep studies, as well as potentializing the kinetic aspect usually existent in academic groups.

Metodologia de Avaliação Usando Questionários com Escalas Não-numéricas: A Visão do Aluno e a Visão do Professor

Ronei Marcos de Moraes[1]

Resumo — *Este trabalho propõe uma nova metodologia de avaliação da qualidade do ensino ministrado em disciplinas de graduação. Nesta metodologia, alunos e também professores opinam através de questionários com escalas não-numéricas sobre a qualidade do ensino. Uma breve história da evolução desta metodologia é apresentada, bem como as dificuldades encontradas na sua aplicação. Um estudo de caso também é apresentado mostrando algumas das interessantes características deste tipo de questionário, como um alto índice de respostas válidas e o reduzido tempo de coleta dos dados. Neste estudo ficou constatado que alunos e professores tem visões similares das questões que envolvem uma disciplina, mesmo quando a variabilidade das opiniões individuais pareça indicar o contrário. A metodologia apresentada é genérica o bastante para poder ser aplicada também em outras situações de ensino que não o terceiro grau ou mesmo em avaliação da qualidade de um treinamento ministrado.*

Palavras-chave — Avaliação Docente e Discente, Questionários com Escalas Não-numéricas, Qualidade do Ensino, Ensino Superior.

INTRODUÇÃO

Há tempos a questão da avaliação da qualidade do ensino ministrado em sala de aula e a sua melhoria vem sendo analisada e questionada. Vários aspectos desse problema tem sido estudados, desde a proposta de novas formas de ensino de tópicos ou assuntos isolados [8, 10, 30], ou propostas de ementa [26], passando pela reforma de currículos inteiros [32].

Vários tipos de metodologias foram propostas para a modernização e melhoria da qualidade de ensino. Algumas delas são baseadas em participação ativa do aluno no processo ensino-aprendizado [33], ensino por projetos [36], ensino cooperativo [3], ensino assistido por computador [5], disponibilidade de material didático multimídia [17], video-conferência ou TV [34], ensino e avaliação via Web [9, 16], aprendizado com o auxílio de realidade virtual [35, 25], inteligência artificial [23] e até mesmo o uso de redes de computadores [24].

Apesar da sofisticação e da modernização digital do ensino provocar discussões [4], a avaliação de qualidade é o que realmente demonstra se houve melhorias de fato no ensino [28]. Várias formas de avaliação tem sido propostas, desde a avaliação pelos estudantes de uma disciplina [19], a avaliação em vários estágios na instituição [1, 32] até a avaliações em larga escala [6, 14]. Em vários estados no Brasil e outros países, diferentes tipos de avaliação da qualidade de ensino orientam reformas e ditam políticas educacionais [13] e até mesmo o intercâmbio educacional entre países [2].

Seguindo a mesma filosofia, a avaliação da qualidade do ensino pelos estudantes de um curso tem sido a base para muitas reformas curriculares, tanto de tópicos ou disciplinas isoladas como de cursos inteiros, visto que a melhoria do ensino, necessariamente passa pelo elemento fim deste elo: o aluno que recebe o ensinamento. No Brasil, essas reformas iniciaram-se a partir da nova Lei de Diretrizes e Bases da Educação Nacional (LDB) de 1996 (Lei número 9394/96).

Em particular, várias formas de avaliação através de questionários vem sendo tentadas e cada uma delas, em sua particularidade, vem contribuir em algum aspecto. Do ponto de vista estatístico, os questionários de avaliação tem como preocupação a objetividade e a qualidade dos dados a serem fornecidos [12] pelos alunos e devem cumprir pelo menos duas funções: descrever as características individuais e medir determinadas variáveis de um grupo em estudo [31]. Para atingir esses pontos é essencial a utilização de questões simples, preferencialmente fechadas, de múltipla resposta e em número reduzido [27]. O aspecto da confiabilidade dos dados pode ser "checados" com perguntas de teste, visando entender à realidade do "prestador da informação": o aluno e a qualidade da sua resposta [19, 20]. Com isso, busca-se vencer barreiras comuns nas atividades docentes como o receio por parte do professor da avaliação feita por parte dos alunos (quase sempre taxada como imatura) e obter respostas mais próximas à realidade, evitando alguns tipos de distorções. No entanto, entre o professor e o aluno, existem outros meios que podem atrapalhar o andamento do curso, como por exemplo, as condições do local de aula, greves, motivação, entre outras. Em Moraes e Melo, [20], além das formas habituais de cruzamento de informações, através de tabelas e gráficos, propõe-se quatro índices para avaliar a qualidade média do professor, qualidade média do aluno e motivação dos alunos. Cada índice procura mostrar a visão dos alunos a respeito do professor e de si mesmo, além de proporcionar um quinto índice sobre a colaboração média dos alunos naquela pesquisa, baseado na coerência das respostas obtidas.

Neste trabalho, procuramos aperfeiçoar a forma de avaliação que utiliza um tipo de questionário proposta por

[1] Ronei Marcos de Moraes, Departmento de Estatística, Universidade Federal da Paraíba, Cidade Universitária s/n CEP 58.051-900 João Pessoa – PB - Brasil, tel.: +55 83 216-7075, ronei@de.ufpb.br

Moraes [19, 20], no qual uma mistura de ingredientes visa deixar o aluno mais à vontade para responder e ao mesmo tempo não deixar muitas questões discursivas para o aluno responder. Notadamente, esse último tipo de questão acarreta em um grande número de não-respostas. Assim, em substituição a questões com respostas de múltipla escolha, que nem sempre contempla todas as opções razoáveis para cada aluno em particular, utilizou-se uma escala. Essa escala não é uma escala numérica, como aquelas comumente utilizadas em pesquisas com perguntas subjetivas, mas sim uma escala contínua na forma de uma reta, com comprimento fixo para todas as questões e com indicações sobre o significado das extremidades direita e esquerda.

Pelo fato de nem todas as questões poderem ser colocadas desta forma, esse modelo é um híbrido com questões com respostas em escalas, múltiplas escolhas e também discursivas para sugestões ou respostas não contempladas entre as escolhas disponíveis.

Porém, mesmo com as vantagens oferecidas por esse método [19, 20] e dos bons resultados de sua aplicação [15], infelizmente a resistência por parte de alguns professores manteve-se. Para tentar vencê-la e ao mesmo tempo obter novas informações sobre a sala de aula, propomos uma metodologia de avaliação que dê vez também a expressão do professor. Este questionário foi empregado pela primeira vez com sucesso no primeiro semestre de 2000 em uma avaliação docente efetuada na UFPB. Neste trabalho, apresentamos a metodologia utilizada na confecção de ambos os questionários, bem como alguns resultados dessa primeira experiência.

HISTÓRICO METODOLÓGICO

O primeiro questionário para a avaliação da qualidade de ensino no Departamento de Estatística da UFPB foi proposto em 1992. Esse questionário sofreu modificações e aperfeiçoamentos [19, 20] e permaneceu em uso até 1998. Esse questionário era composto por questões que abrangiam a relação professor-aluno dentro e fora da sala de aula, bem como as condições das instalações, a forma de estudo, motivação, relação com os colegas de sala, etc.

Como a proposta de avaliação e o próprio questionário sempre estiveram abertos a críticas e sugestões dos alunos e professores, sentiu-se a necessidade de buscar uma alternativa para algumas questões de múltipla escolha que não contemplavam precisamente o desejo de expressão do aluno. A solução encontrada foi a adoção inicial de uma escala numérica do tipo *likert* (Pasquali, 1998). No entanto, essa escala sofreu críticas variadas por parte dos alunos, tanto por ser considerada insuficiente para alguns, como ser muito além do necessário para outros.

A solução final foi a adoção de uma escala desprovida de números: uma linha reta, com comprimento fixo para todas as questões e com indicações sobre o significado das extremidades direita e esquerda, sobre a qual o aluno pode colocar um ponto ou um círculo, conforme mostra a Figura 1 [22]. Este tipo de escala não-numérica elimina também a dúvida sobre a quantificação dos níveis entre um intervalo e outro observado, por exemplo, nas escalas do tipo *likert*.

|---|

Atitude Fortemente Positiva	Atitude Fortemente Negativa

FIGURA. 1
O TIPO DE ESCALA UTILIZADO, COM AS EXTREMIDADES DO SEGMENTO DE RETA IDENTIFICADOS RESPECTIVAMENTE, COMO UMA ATITUDE POSITIVA E ATITUDE NEGATIVA POR PARTE DO PROFESSOR.

Para medir a resposta do aluno atribui-se como o "zero" da escala a Atitude Fortemente Positiva e como a pontuação máxima a Atitude Fortemente Negativa (por exemplo, cinco, sete ou dez centímetros, dependendo do comprimento do segmento de reta). A partir dessa escala é possível quantificar a pontuação que o aluno está atribuindo ao professor, medindo-se o comprimento da reta até o ponto médio do círculo ou do ponto desenhado na reta. Essa solução teve uma aceitação bastante expressiva em sucessivas aplicações [15, 19]. A metodologia propôs o uso do questionário por duas vezes - na metade do período letivo e ao seu final - ou até mesmo três vezes aos alunos, quando sabido haver algum tipo de problema na disciplina.

Uma informação bastante interessante que pode ser obtida pela utilização deste tipo de questionário é a adequação do professor à disciplina, se comparado o seu desempenho entre as várias disciplinas que ministra naquele período. Essa informação pode levar a um aperfeiçoamento da distribuição de certas disciplinas a professores que realmente se dão bem em ministrá-las, levando os professores que não obtém bons resultados a ministrar outras disciplinas (nas quais obteve bons resultados), ou mesmo a uma reciclagem.

Porém, vários comentários maldosos por parte dos alunos para com alguns professores mais exigentes e comentários extremamente favoráveis a professores menos exigentes levantaram novamente a questão da maturidade do aluno que responde a esse tipo de questionário e se essa técnica de avaliação é realmente eficaz. Então, para buscar mais informações a respeito do que de fato acontece em um curso, seja na sala de aula ou fora dela, criamos um questionário similar ao primeiro direcionado ao professor. Esse novo questionário procura verificar a visão do professor sobre temas similares aos perguntados aos alunos. Em algumas questões, o professor é convidado a refletir sobre os seus próprios parâmetros de ensino; em outras, ele pode opinar sobre melhorias a serem realizadas no sentido de melhorar o desempenho da sala e o seu próprio.

OS QUESTIONÁRIOS

O questionário direcionado aos alunos levanta fatores importantes como, por exemplo, a qualidade do aluno que recebe o ensinamento, a sua metodologia de estudo, a sua preocupação com a ementa e com o seu futuro pós-escola. Enfim, o aluno avalia o desempenho do seu professor, o seu próprio, a ementa e os seus colegas. Pelo caráter dinâmico deste tipo de questionário, a partir de novas sugestões e críticas de alunos e professores, novas alterações poderão ser efetuadas. A composição básica desse questionário segue três linhas-mestras: a primeira visa conhecer as relações aluno-professor, vista por parte do aluno; a segunda visa estabelecer as relações entre o aluno e a disciplina que está sendo cursada; e a terceira visa conhecer o universo no qual o aluno está inserido e as suas relações com ele. Cada tópico está intimamente relacionado com o seguinte na tentativa de conhecer o ambiente da sala de aula sob a ótica do aluno e de certa forma tentando captar as contradições inerentes a este ambiente. Esse questionário possui ao todo 22 questões, sendo uma para sugestões e outras três para identificação do curso, período e se já cursou ou não a disciplina anteriormente. O aluno não é identificado, a menos que o faça por sua própria vontade.

O questionário direcionado ao professor levanta questões quanto à metodologia didática utilizada, qual o percentual da ementa foi cumprida (muito importante para disciplinas que são pré-requisitos de outras), horários de atendimento aos alunos, acesso à bibliografia, condições de sala de aula, assiduidade dos alunos e do próprio professor, dificuldades dos alunos que chegaram ao seu conhecimento, procura por monitores e pelo próprio professor fora da sala, etc. A estrutura deste questionário segue a mesma estrutura do questionário formulado para os alunos. Esse questionário possui ao todo 18 questões, sendo uma para sugestões e outras seis para identificação do curso, período, turma, número de vezes que já ministrou a disciplina, percentual da ementa cumprida e número de horas de atendimento extra-classe. Ao contrário do aluno, o professor é identificado.

ESTUDOS DE CASO

Usando os dados reais da experiência realizada em 2000, a seguir é dado um exemplo da análise dos dados provenientes deste tipo de questionário. Foram aplicados questionários em uma turma de Estatística IV (formada essencialmente por alunos da Psicologia), período diurno, no primeiro semestre de 2000, na Universidade Federal da Paraíba. A aplicação do questionário deu-se em uma data sorteada aleatoriamente entre a segunda e a terceira avaliação. Estavam presentes nesta data na sala de aula 25 alunos. O índice de respostas válidas nas questões (treze questões) com respostas nas escalas não numéricas foi de 100%. Nas questões de múltipla escolha (cinco questões), o índice também foi de também 100%. Das quatro perguntas abertas, apenas em uma (sugestões para melhoria do curso), o índice caiu para 68%. O tempo total utilizado pelos alunos para responder o questionário foi próximo dos dez minutos.

O professor, sem o conhecimento prévio das respostas dos alunos, respondeu ao questionário apenas ao final do semestre - essa defasagem no tempo é necessária, pois algumas perguntas referem-se ao rendimento final dos alunos da disciplina (no caso dos alunos, a pergunta equivalente refere-se a esperança de ser aprovado na mesma disciplina). Na aplicação do questionário do professor o índice de respostas válidas foi de 100% em todos os três tipos de pergunta. Esse questionário era composto por oito questões em escalas não-numéricas, quatro de múltipla escolha e seis abertas. O tempo utilizado pelo professor para responder o questionário foi cerca de sete minutos.

Como uma primeira ilustração, pode ser utilizada uma questão polêmica: "O nível das aulas é condizente com o de exercícios de avaliação", avaliada pelos alunos e "Avalie o nível dos exercícios (das listas e de sala de aula) com as provas e trabalhos", avaliada pelo professor. A escala para ambos foi apresentada com um comprimento total de 8 cm e o padrão de medida utilizado foi da esquerda para a direita. Portanto, valores muito próximos de zero (lado esquerdo do segmento de reta) significam a total coerência entre o nível dos exercícios apresentados em sala de aula e as provas e trabalhos. Valores próximos ao centro (quatro centímetros) indicam uma dúvida ou neutralidade do aluno ou do professor a respeito da sua avaliação. No sentido oposto (lado direito do segmento de reta), valores muito próximos de oito significam a total incoerência entre os exercícios.

Para essa questão, a resposta média dos alunos foi 1,249 com desvio-padrão de 1,003. O professor respondeu no ponto médio 0,6 com variação entre zero e 1,2. Podemos considerar próximas as visões dos alunos e a do professor no quesito compatibilidade entre as aulas e a avaliação, mesmo com a diferença dos pontos médios, visto que 76% dos alunos colocaram um ponto médio abaixo do comprimento de 2,0 cm e apenas dois alunos colocaram um ponto médio acima dos 3,0 cm. Essa questão ilustra a necessidade de se observar não apenas os pontos médios, mas também o percentual de alunos que concordam ou discordam com a visão do professor, dada pela amplitude de resposta do professor.

Como uma segunda ilustração, pode ser utilizada a questão: "Você acha que a ementa dessa disciplina vem de encontro ao seu curso?", avaliada pelos alunos e "A ementa dessa disciplina é razoável para a formação dos futuros profissionais nessa área?", avaliada pelo professor. A escala para ambos foi novamente a de 8 cm, com padrão de medida da esquerda para a direita. Valores muito próximos de zero (lado esquerdo do segmento de reta) significam a total concordância com a adequação da ementa ao curso. Valores próximos ao centro (quatro centímetros) indicam uma dúvida ou neutralidade e valores assinalados no lado direito do segmento de reta, (próximos de oito) significam a total discordância com a adequação da ementa ao curso.

Nesse caso, a resposta média dos alunos foi 2,667 com desvio de 2,065. O professor respondeu no ponto médio 1,95 com variação entre 1,4 e 2,5. Novamente, podemos observar a grande intersecção entre as respostas dos alunos e a do professor. Nesse caso, 60% dos alunos responderam com valores semelhantes ao do professor no segmento de reta, demonstrando a intersecção nas respostas. Apenas três alunos assinalaram um ponto médio acima dos 4,0 cm. É interessante notar que apesar das diferenças aparentes entre as opiniões, o professor assinalou um comentário interessante a respeito da sua resposta: "Os alunos utilizarão métodos estatísticos até mais sofisticados do que estes, porém, a base matemática deficiente complica o ensino dos tópicos".

É também digno de nota que 40% dos alunos declararam que a sua principal dificuldade no estudo da disciplina é a base matemática deficiente. No questionário do professor uma questão similar é colocada e as respostas são: base matemática deficiente e os atrasos freqüentes dos alunos.

CONCLUSÕES FINAIS

Este artigo apresenta uma metodologia para avaliação docente e discente, na qual alunos e professores opinam sobre várias questões envolvendo uma disciplina. Estas questões abrangem a metodologia de ensino, estrutura escolar, forma de estudo, atendimentos extra-classe, etc. Também é apresentado um estudo de caso envolvendo uma disciplina ministrada na Universidade Federal da Paraíba.

Pelos dados, pode-se notar que a utilização das escalas não-numéricas simplificou a coleta de dados com um índice de respostas válidas próximo a 100%, também nas questões de múltipla escolha e abertas. O número reduzido de questões também contribuiu para a obtenção desse índice. Percentuais similares de respostas válidas já tinham sido obtidos por essa metodologia em sucessivas aplicações anteriores [15, 20], ratificando a eficiência do método quando aplicado aos alunos.

No caso particular das respostas do professor, os índices de respostas também foram altos. É digno de nota que em boa parte das respostas, as visões de alunos e professores sobre o ensino coincidem. Naturalmente, houve algumas poucas divergências e uma maior dispersão de opiniões no alunado. Para verificar essas divergências, pode-se utilizar os índices propostos por Moraes e Melo [20].

Uma interessante característica dessa metodologia é ser suficientemente genérica para poder ser aplicada em outras situações de ensino ou treinamento. O método de análise apresentado, baseado nos percentuais das intersecções de respostas, apesar de simples é funcional, pois revela o grau de similaridade de pensamentos entre os alunos e professor. Nos casos analisados nesse trabalho, essa similaridade de pensamentos foi detectada e mostra a existência de uma sintonia entre a percepção dos alunos e do professor sobre o que ocorre na sala de aula.

É óbvio que se deve levar em consideração que existe uma diferença de óticas na resposta dos questionários dos alunos e professores, da a natureza dos papéis dentro da sala-de-aula. No entanto, a existência dessa similaridade de pensamentos se revela devido ao cuidado demonstrado na confecção dos questionários, buscando a avaliação dos pontos importantes da didática, do comportamento, dos pré-requisitos, da maturidade e da seriedade de professores e alunos na busca da melhoria da qualidade do ensino. Observando essas premissas, podemos minimizar as críticas dos docentes a respeito da tão propagada imaturidade dos alunos em seus julgamentos do que de fato ocorre na sala-de-aula, diminuindo alguns tipos de distorções e obtendo respostas mais próximas à realidade de ambos os lados.

Futuramente, com um modelo de questionário aperfeiçoado para o professor, esperamos reduzir ainda mais o número de questões abertas, transformando-as em escalas não-numéricas, facilitando ainda mais a coleta dos dados.

AGRADECIMENTOS

O autor agradece aos alunos e professores que desde 1992 participam voluntariamente desse projeto para a melhoria da qualidade de ensino.

IMPLEMENTAÇÃO EM TEMPO REAL DE UM SISTEMA DE RECONHECIMENTO DE FALA CONTÍNUA

Carlos A. Ynoguti[1] & J. Domingos Adriano[2]

Resumo *— A popularização dos computadores pessoais e a generalização de aplicações computacionais na vida das pessoas exigem o desenvolvimento de interfaces homem-máquina mais amigáveis. Das formas de comunicação do ser humano, a mais natural é a fala. Assim, interfaces baseadas na fala que permitam a comunicação em tempo real com uma máquina apresentam várias possibilidades de aplicação. Entretanto, a construção de sistemas que operam em tempo real é uma tarefa bastante complexa, pois envolve análises de problemas que não são encontrados em protótipos que não operam deste modo. Neste trabalho é apresentado um software para reconhecimento de fala contínua, independente do locutor, e que opera em tempo real, usando a técnica de Modelos Ocultos de Markov.*

Palavras Chave — reconhecimento de fala, processamento de voz, sistemas em tempo real.

INTRODUÇÃO

Poder comunicar-se com computadores e outras máquinas através da fala é um sonho antigo, que motivou vários pesquisadores ao longo de várias décadas. Graças a esse esforço de pesquisa, iniciado na década de 50, atualmente já podem ser encontrados os primeiros sistemas de reconhecimento de fala de aplicação comercial. Contudo ainda existe muito a ser aperfeiçoado até que seja criado um sistema que permita a comunicação entre máquinas e pessoas através da fala de uma forma natural.

Uma interface baseada na fala é mais amigável e, dependendo de como é implementada, faz com que não sejam necessários conhecimentos específicos, facilitando a comunicação dos sistemas informatizados com as pessoas, reduzindo assim a exclusão social causada pela falta de domínio das novas tecnologias.

Outras possíveis aplicações para sistemas de reconhecimento de fala são:

- controle de máquinas via voz, deixando as mãos do operador livres para executarem outras tarefas;
- controle de funções de um automóvel (por exemplo, faróis, vidros, limpadores de pára-brisas e rádio), o que ajudaria a evitar acidentes;
- telefone para surdos: uma pessoa que deseja telefonar para uma pessoa com deficiência auditiva poderia falar normalmente. Na casa do deficiente, um sistema de reconhecimento poderia, por exemplo, escrever em uma tela o que a outra pessoa falasse, ou controlar uma cabeça artificial, que mexeria a boca conforme o que estivesse sendo falado para que o deficiente fizesse uma leitura labial;
- auxílio a pessoas deficientes: pessoas paraplégicas ou tetraplégicas poderiam controlar cadeiras de rodas e computadores através de comandos de voz;

Este artigo descreve um sistema de reconhecimento de fala contínua baseado em Modelos Ocultos de Markov contínuos, independente de locutor, para vocabulários pequenos, e que opera em tempo real.

RECONHECIMENTO DE FALA

O processo de reconhecimento de fala consiste em mapear um sinal acústico, capturado por um transdutor (usualmente um microfone ou um telefone) em um conjunto de palavras.

Os sistemas de reconhecimento de fala podem ser caracterizados por vários parâmetros sendo que alguns dos mais importantes se encontram resumidos na Tabela 1 [3].

Tabela 1: Parâmetros típicos usados para caracterizar a capacidade de sistemas de reconhecimento de fala.

Parâmetros	Faixa
Modo de Pronúncia	palavras isoladas a fala contínua
Estilo de pronúncia	leitura a fala espontânea
Treinamento	dependente de locutor a independente de locutor
Vocabulário	pequeno (< 20 palavras) a grande (> 20000 palavras)
Modelo de linguagem	estados finitos a sensível a contexto
Perplexidade	pequena (< 10) a grande (> 100)
SNR	alta (> 30 dB) a baixa (< 10 dB)
Transdutor	microfone com cancelamento de ruído a telefone

Um sistema de reconhecimento de palavras isoladas requer que o locutor efetue uma pequena pausa entre as palavras, enquanto que um sistema de reconhecimento de fala contínua não apresenta este inconveniente.

A fala quando gerada de modo espontâneo é mais relaxada, contém mais coarticulações, e portanto é muito mais difícil de reconhecer do que quando gerada através de leitura.

[1] Carlos Alberto Ynoguti, INATEL – Instituto Nacional de Telecomunicações, Av. João de Camargo, 510, 37.540-000 Santa Rita do Sapucaí, MG, Brasil, yoguti@inatel.br
[2] José Domingos Adriano, INATEL – Instituto Nacional de Telecomunicações, Av. João de Camargo, 510, 37.540-000 Santa Rita do Sapucaí, MG, Brasil, jose-adriano@inatel.br

Os sistemas dependentes de locutor necessitam de uma fase de treinamento para cada usuário antes de serem utilizados, o que não acontece com sistemas independentes do locutor, desde que estes já foram previamente treinados com vários locutores.

O reconhecimento torna-se mais difícil à medida em que o vocabulário cresce, ou apresenta palavras parecidas.

Quando a fala é produzida em seqüências de palavras, são usados modelos de linguagem para restringir as possibilidades de seqüências de palavras. O modelo mais simples pode ser definido como uma máquina de estados finita, onde são explicitadas as palavras que podem seguir uma dada palavra. Os modelos de linguagem mais gerais, que aproximam-se da linguagem natural, são definidos em termos de gramáticas sensíveis a contexto.

Uma medida popular da dificuldade da tarefa, que combina o tamanho do vocabulário e o modelo de linguagem, é a *perplexidade*, grosseiramente definida como a média do número de palavras que pode seguir uma palavra depois que o modelo de linguagem foi aplicado.

Existem também parâmetros externos que podem afetar o desempenho de um sistema de reconhecimento de fala, incluindo as características do ruído ambiente e o tipo e posição do microfone.

O reconhecimento de fala é um problema difícil devido às várias fontes de variabilidade associadas ao sinal de voz [3]:

- *variabilidades fonéticas* : as realizações acústicas dos fonemas, a menor unidade sonora das quais as palavras são compostas, são altamente dependentes do contexto em que aparecem [1]. Por exemplo o fonema /*t*/ em *tatu* tem uma articulação puramente oclusiva, e em *tia*, dependendo do locutor, pode ter uma articulação africada, onde à oclusão se segue um ruído fricativo semelhante ao do início da palavra "chuva". Além disso, nas fronteiras entre palavras, as variações contextuais podem tornar-se bem mais acentuadas fazendo, por exemplo, com que a frase '*a justiça é ...*' seja pronunciada como '*ajusticé...*'
- *variabilidades acústicas*: podem resultar de mudanças no ambiente assim como da posição e características do transdutor.
- *variabilidades intra-locutor*: podem resultar de mudanças do estado físico/emocional dos locutores, velocidade de pronúncia ou qualidade de voz.
- *variabilidades entre-locutores*: originam-se das diferenças na condição sócio - cultural, dialeto, tamanho e forma do trato vocal para cada uma das pessoas.

Os sistemas de reconhecimento tentam modelar as fontes de variabilidade descritas acima de várias maneiras:

- Em termos fonético acústicos, a variabilidade dos locutores é tipicamente modelada usando técnicas estatísticas aplicadas a grandes quantidades de dados de treinamento. Também têm sido desenvolvidos algoritmos de adaptação ao locutor que adaptam modelos acústicos independentes do locutor para os do locutor corrente durante o uso [14][17].
- As variações acústicas são tratadas com o uso de adaptação dinâmica de parâmetros [14], uso de múltiplos microfones [15] e processamento de sinal [3].
- Na parametrização dos sinais, os pesquisadores desenvolveram representações que enfatizam características independentes do locutor, e desprezam características dependentes do locutor [4][5].
- Os efeitos do contexto lingüistico em termos fonético-acústicos são tipicamente resolvidos treinando modelos fonéticos separados para fonemas em diferentes contextos; isto é chamado de modelamento acústico dependente de contexto [8].
- O problema da diferença de pronúncias das palavras pode ser tratado permitindo pronúncias alternativas de palavras em representações conhecidas como redes de pronúncia. As pronúncias alternativas mais comuns de cada palavra, assim como os efeitos de dialeto e sotaque são tratados ao se permitir aos algoritmos de busca encontrarem caminhos alternativos de fonemas através destas redes. Modelos estatísticos de linguagem, baseados na estimativa de ocorrência de seqüências de palavras, são geralmente utilizados para guiar a busca através da seqüência de palavras mais provável [6].

Atualmente, os algoritmos mais populares na área de reconhecimento de fala baseiam-se em métodos estatísticos. Dentre estes, dois métodos têm se destacado: as redes neurais artificiais (*Artificial Neural Networks*, ANN) [16] e os modelos ocultos de Markov (*Hidden Markov Models*, HMM) [7]. Mais recentemente, implementações híbridas que tentam utilizar as características mais favoráveis de cada um destes métodos também têm obtido bons resultados [13].

SISTEMA IMPLEMENTADO

A rigor, um sistema que opera em tempo real deve ser capaz de efetuar todas as operações a uma taxa maior ou igual à taxa com que o sinal de entrada chega. Devido às verificações efetuadas pelo modelo de linguagem, não é possível atender a este critério. Entretanto, do ponto de vista do usuário, para que se tenha a impressão de operação em tempo real, basta que o tempo de resposta seja tal que o atraso devido ao processamento não seja perceptível (ou demasiadamente longo), e foi baseado nesta premissa que este sistema foi implementado.

Como tecnologia básica, foi escolhido o método baseado em modelos ocultos de Markov contínuos com modelamento por subunidades fonéticas. Para estas foram escolhidos os fones independentes de contexto[6]. Na Figura 1 tem-se um diagrama em blocos do sistema implementado.

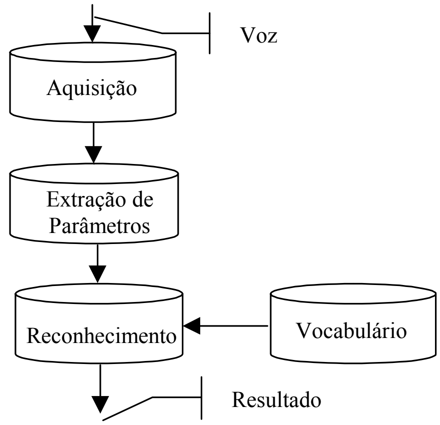

FIGURA 1
DIAGRAMA EM BLOCOS DE UM SISTEMA DE RECONHECIMENTO DE FALA.

Neste diagrama, podemos identificar os seguintes módulos:

1. **Módulo de aquisição de dados**: responsável por converter um sinal analógico, proveniente de um microfone, para um sinal digital em formato PCM.
2. **Módulo de extração de parâmetros**: tem por função converter o sinal de voz em uma seqüência de vetores de parâmetros. Isto é feito com o objetivo de representar os eventos acústicos relevantes do sinal de fala em termos de um conjunto compacto e eficiente de parâmetros.
3. **Módulo de reconhecimento**: por fim, a locução parametrizada é inserida no módulo de reconhecimento, que tem por função comparar a seqüência de parâmetros da locução a ser reconhecida com os modelos nele armazenados. A palavra cujo modelo que apresentar a maior similaridade com a locução de entrada vai ser a palavra reconhecida.

A seguir, cada um destes itens será mostrado em maiores detalhes:

Módulo de aquisição

Como dito anteriormente, este módulo é a interface do sistema com o usuário: coleta os sinais acústicos provenientes de um microfone e os apresenta para serem processados. Entretanto, como os algoritmos de reconhecimento apresentam um alto custo computacional, seria interessante que este só entrasse em ação quando houvesse um sinal de voz presente, deixando os recursos do sistema livres para outros aplicativos enquanto o locutor não estiver falando.

Analisando um sinal típico de a fala, nota-se que grande parte do tempo de uma conversação é ocupado por silêncio, como pode ser observado na Figura 2. Desta forma, para otimizar a utilização do sistema de reconhecimento, os intervalos de silêncio devem ser descartados, sendo processada somente a fala válida. Neste trabalho foi desenvolvido um algoritmo baseado em níveis de energia, uma adaptação do método proposto no artigo clássico de Rabiner & Sambur [11].

A identificação da presença de fala válida no sinal adquirido pode ser feita de várias formas, e a dificuldade em fazê-la depende do ambiente onde se encontra o locutor, pois a ausência de fala não significa silêncio absoluto. De fato, na maioria das aplicações práticas sempre haverá um ruído de fundo. Em ambientes demasiadamente ruidosos serão encontradas dificuldades para distinguir a fala do ruído não só na aquisição como também na etapa de reconhecimento.

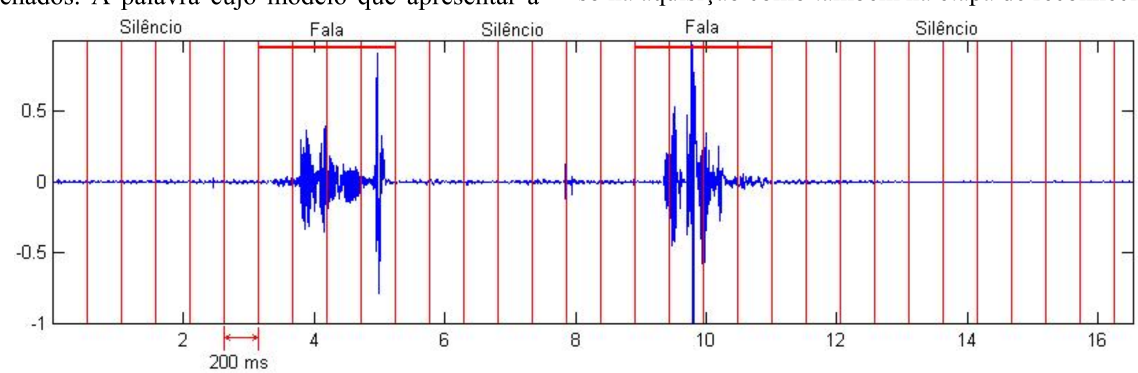

FIGURA 2
DIAGRAMA DO SISTEMA DE RECONHECIMENRO DE FALA

Para ambientes com uma relação sinal-ruído razoável uma técnica que apresenta bons resultados é a análise do nível de energia do sinal. Considerando que o sinal de voz do locutor possui um nível de energia notavelmente superior ao nível do sinal de energia do ruído, é possível identificar os intervalos que possuem fala.

Para isto, inicialmente é necessário medir o nível de sinal quando não se tem sinal de voz presente, isto é, o nível de energia do ruído ambiente. Depois, quando em operação, o sistema verifica se a entrada ultrapassa um determinado limiar acima do nível do ruído, e quando isto acontece, o sinal é enviado ao sistema de reconhecimento.

A aplicação do algoritmo de detecção de início e fim pode ser exemplificado pela

Figura 3, que apresenta a forma de onda de uma palavra, seus níveis de energia e as marcações de inicio e fim.

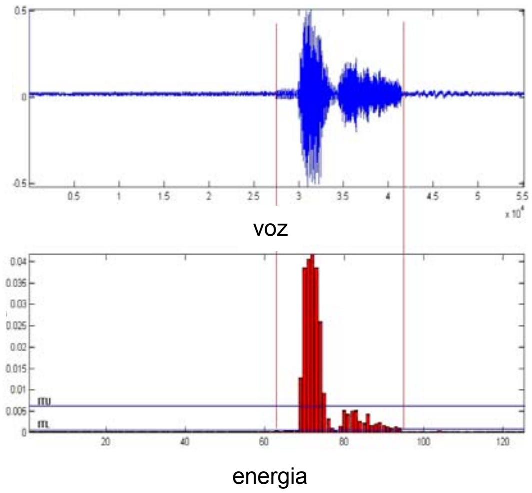

FIGURA 3
APLICAÇÃO DO ALGORITMO DE DETECÇÃO DE INICIO E FIM NA PALAVRA 'DOIS'.

Módulo de extração de parâmetros

A próxima etapa consiste na extração de parâmetros do sinal de voz. Para este trabalho foram escolhidos os parâmetros mel-cepstrais [4], amplamente utilizados na maioria dos sistemas de reconhecimento de fala atuais.

O processo de obtenção dos parâmetros acústicos da fala envolve 3 etapas: a pré-ênfase, o janelamento e a análise espectral, representadas conforme a Figura 4.

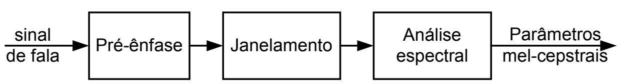

FIGURA 4
DIAGRAMA DE BLOCOS DO PROCESSO DE EXTRAÇÃO DOS PARÂMETROS MEL-CEPSTRAIS

A pré-ênfase, realizada por um filtro passa altas ($1 - 0,95z^{-1}$), tem como função compensar a atenuação de 6dB/oitava nas altas freqüências. Esta atenuação é ocasionada pelo efeito combinado do espectro decrescente dos pulsos glotais (-12dB/oitava) e pelo efeito de radiação dos lábios (+6dB/oitava) [10].

Os parâmetros do sinal de fala são atualizados a cada 10 ms, sendo o janelamento do sinal calculado através da janela de Hamming de 20 ms. Este janelamento tem como função produzir suavização da amplitude do sinal amostrado, nos extremos do segmento de análise, dando maior ênfase às amostras localizadas no centro da janela. Desta forma, tem-se uma superposição entre os dados de análise de 2 janelas adjacentes. Este processo pode ser observado na Figura 5.

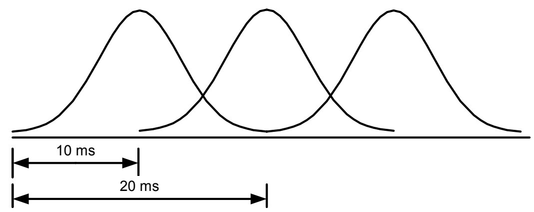

FIGURA 5
PROCESSO DE SUPERPOSIÇÃO DE JANELAS PARA O CÁLCULO DOS PARÂMETROS MEL-CEPSTRAIS

Como finalização do processo, têm-se a análise espectral, onde é realizada a conversão da representação temporal do sinal analisado, para alguma forma de representação espectral. Basicamente dois métodos de análise espectral predominam nos sistemas de reconhecimento de fala: o método de análise espectral LPC (Linear Predictive Coding) e o método de análise espectral por banco de filtros, obtido a partir da Transformada Rápida de Fourier (FFT). Para este trabalho, optou-se pelo segundo método, por ser mais eficiente na obtenção dos parâmetros mel-cepstrais.

Tanto o espectro resultante da FFT quanto o espectro resultante da predição linear são representações bem mais relacionadas ao processo de audição e percepção humana do que os métodos de representação temporal (taxa de cruzamentos por zero, perfil de energia, log-energia, entre outros), utilizados na caracterização da fala. Isto justifica a ampla utilização de parâmetros extraídos a partir da representação espectral do sinal acústico, em relação aos parâmetros de representação temporal.

Além dos parâmetros cepstrais (mel-cepstrais), foram utilizados também os parâmetros diferenciais (delta-mel-cepstrais, delta-delta-mel-cepstrais), com o intuito de uma melhor caracterização das variações temporais do sinal de fala.

Módulo de reconhecimento

O módulo de reconhecimento é o responsável pelo mapeamento dos parâmetros acústicos correspondentes à locução de entrada em sua transcrição ortográfica. Foram implementados três algoritmos de busca para o reconhecimento de fala contínua: o *Level Building* [11], o *One Step* [9] e o Herrman-Ney [2]. Para melhorar o desempenho do sistema em termos de taxa de acertos foram incluídos o modelo de duração de palavras [12] e o modelo de linguagem bigrama [6]. Também foi implementada a estratégia Viterbi *Beam Search* [12] de poda de caminhos. para diminuição do custo computacional e consequentemente do tempo de processamento. Um diagrama de blocos para este sistema é mostrado na Figura 6.

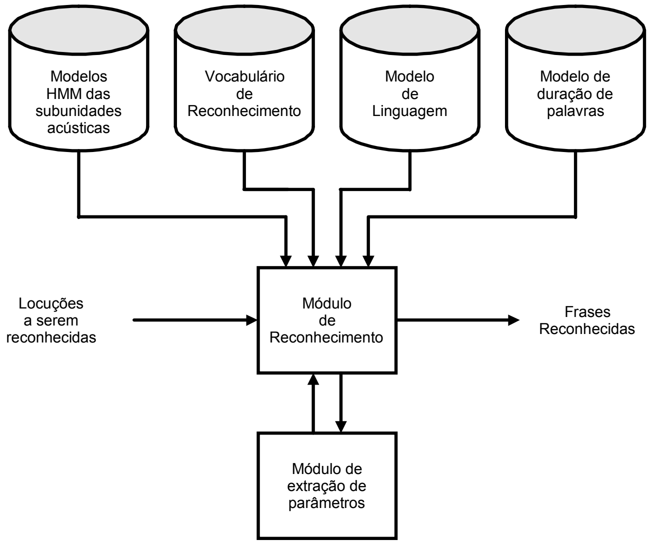

FIGURA 6
DIAGRAMA DE BLOCOS DO MÓDULO DE RECONHECIMENTO.

Estes algoritmos são extremamente complexos, e a descrição detalhada dos mesmos foge do escopo deste trabalho. Em [12] tem-se uma boa referência para o estudo dos mesmos.

Uma consideração importante a ser feita é sobre o tamanho do vocabulário, ou seja, o número de palavras que o sistema pode reconhecer. Quanto maior o vocabulário, maior será o tempo necessário para que uma palavra seja reconhecida. Com estes algoritmos, temos conseguido, para este sistema, operação em tempo real para vocabulários de algumas dezenas de palavras. Outros algoritmos de reconhecimento, mais eficientes estão sendo estudados para permitir operação em tempo real para vocabulários maiores.

CONCLUSÃO

Neste artigo foi apresentado um breve resumo da tecnologia de reconhecimento de fala e suas aplicações, bem como a descrição da implementação em tempo real de um sistema de reconhecimento de fala contínua independente de locutor baseado em modelos ocultos de Markov, para um vocabulário pequeno.

A implementação de um sistema para operação em tempo real apresenta dificuldades que não são encontradas em protótipos de laboratório que não operam em tempo real, levando a considerações e a soluções próprias deste tipo de sistema. Ainda, do ponto de vista da pesquisa, é possível testar novas idéias e soluções em um sistema real, verificando o ganho obtido e mesmo a viabilidade das idéias concebidas.

AGRADECIMENTOS

À FAPEMIG pelo financiamento parcial desta pesquisa. Processo TEC 85015/01.

A Evolução da Alfabetização Brasileira na Última Década: Uma Análise Espacial e Temporal

Izabel Cristina Alcantara de Souza [1] *e Ronei Marcos de Moraes* [2]

Resumo *— O Brasil divulgou recentemente parte dos resultados do Censo Brasileiro de 2000. Entre os dados divulgados estão os índices de alfabetização por estado brasileiro. As primeiras informações davam conta que o índice de analfabetismo brasileiro caiu significativamente. Porém, ficou sem resposta a questão da verdadeira mudança estrutural do analfabetismo brasileiro. As políticas implementadas e experimentadas ao longo da última década foram suficientes para alterar o grave quadro do analfabetismo brasileiro do Censo de 1991? Para responder a essa questão, utilizamos técnicas estatísticas de Análise Espacial para detectar a presença de padrões espaciais existentes no Censo de 1991 e no Censo de 2000, verificar as suas possíveis variações e confrontá-las com os gastos governamentais em ensino fundamental nos últimos anos.*

Palavras-chave — Avaliação do Analfabetismo Brasileiro, Análise Espacial, Índices de Autocorrelação, Geoestatística.

INTRODUÇÃO

A revolução cultural iniciada no final do século XX com o avanço de novas tecnologias, como as telecomunicações e a informática, tem sérias limitações no chamado grupo de países "em desenvolvimento", incluindo o Brasil. A maior parte da população da maioria desses países sofre a exclusão da sociedade informatizada, pelo fato desses países não terem se dedicado a educação básica dos seus povos, ou seja, a alfabetização. As estatísticas oficiais brasileiras demonstram que o Brasil também não fez bem a sua lição de casa até o final da década de 80. Após o Censo Brasileiro de 1991 [6] sabia-se que apenas 66,43% da população brasileira era alfabetizada. Por conseqüência, 33,57% dos brasileiros não eram. Deve-se levar em consideração que em um Censo, a forma de se declarar uma pessoa analfabeta é quando a própria pessoa se declara sem condições de ler e escrever o seu próprio nome. Relembrando a realidade brasileira do final da década de 80, após choques econômicos e a hiper-inflação, o país não possuía elementos favoráveis para um grande salto na educação, ainda que necessitasse deste salto para o seu desenvolvimento. Segundo [8], a heterogeneidade predomina no mapa do Analfabetismo brasileiro em 1991.

A década de 90 foi benéfica no sentido educacional ao Brasil, com vários governantes investindo sistematicamente em grandes programas educacionais e o resultado começou a aparecer no recentemente divulgado Censo Brasileiro de 2000. Após quase uma década, apesar dos percalços econômicos, o Brasil recuou o seu índice de analfabetismo para 24,76% da população no Censo Brasileiro de 2000 [5]. Apesar das melhorias, significativas evidenciadas pelos índices, fica a questão: houve de fato grandes alterações nos quadros estaduais de analfabetismo da nação?

Esse trabalho procura acrescentar novos elementos a essa discussão, a partir de uma análise estatística dos dados governamentais fornecidos. Para realizar essa análise, lançamos mão de técnicas de Análise Espacial [3] para a verificação das reais diferenças ocorridas no Brasil, em termos espaciais, entre os anos de 1991 e 2000.

METODOLOGIA

A avaliação das alterações espaciais entre os Censos de 1991 e 2000 será efetuada através de uma análise espacial utilizando mapas coropléticos (nome dado pela Geografia aos mapas coloridos) [2] e a Associação Espacial de Moran [3]. Essa ferramenta estatística de análise é composta pelos Índices de Moran (Global e Local) e pelos diagramas e mapas de espalhamento. A seguir, os conceitos necessários estão formalizados.

Matriz de Proximidade Espacial

A matriz de proximidade espacial é uma matriz que relaciona n áreas $\{A_1,A_2,...,A_n\}$ de uma região. Essa matriz W é tal que cada um dos seus elementos w_{ij} representa uma medida de proximidade entre as áreas A_i e A_j, segundo um critério de proximidade [3]. Um critério possível é: w_{ij}=1 se A_i compartilha um lado comum com A_j; caso contrário w_{ij}=0.

Média Móvel Espacial

A média móvel espacial $\bar{y}_i$ explora a variabilidade espacial dos dados, procurando determinar variação das tendências. É dada por:

$$\bar{y}_i = (\Sigma^n_{j=1}\ w_{ij}\, y_j\,)\ /\ \Sigma^n_{i=1}\ w_{ij} \qquad (1)$$

onde y_j é o valor do atributo estudado em cada área A_j.

A análise pela média móvel tem a vantagem de produzir uma superfície menos descontínua nos dados originais e isso pode ser visto no mapa coroplético.

[2] Ronei Marcos de Moraes, Departamento de Estatística, Universidade Federal da Paraíba, Cidade Universitária s/n CEP 58.051-900 João Pessoa – PB - Brasil, tel.: +55 83 216-7075, ronei@de.ufpb.br

Índice Autocorrelação Espacial

A média móvel é vista como uma primeira aproximação da variabilidade espacial, mostrando alguns padrões e tendências. Porém, também é importante verificar a dependência espacial dos dados, a fim de verificar a maneira pela qual os dados estão correlacionados no espaço. A autocorrelação espacial procura medir essa dependência espacial de uma área A_i e suas áreas vizinhas, segundo um atributo estudado. Então, Índice Global de Autocorrelação de Moran (I) mede a interdependência geográfica em uma região segundo um atributo e é dado por:

$$I = \left(\sum_{i=1}^{n} \sum_{j=1}^{n} w_{ij} z_i z_j\right) / \left(\sum_{i=1}^{n} z_i^2\right) \quad (2)$$

onde z_i é a diferença entre o valor do atributo na região de estudo e a sua média.

O índice I verifica se as áreas conectadas apresentam algum afastamento de um esperado padrão aleatório. Em geral, seu valor fica limitado ao intervalo [-1, 1], embora em alguns casos possa assumir valores diferenciados. Assim, valores positivos do índice I quantificam correlação direta entre a área em questão e os seus vizinhos, segundo o atributo estudado e os valores negativos quantificam correlação inversa [4].

Segundo Anselin [1], os indicadores locais de autocorrelação devem atender a dois objetivos:

- permitir a identificação de padrões de associação espacial e,
- ser uma decomposição do índice global.

O Índice Local de Moran (I_i) é uma simplificação do índice global, computando a variação do atributo na área A_i pela variação do mesmo atributo em seus vizinhos.

$$I_i = \left(z_i \sum_{j=1}^{n} w_{ij} z_j\right) / \left(\sum_{i=1}^{n} z_i^2\right) \quad (3)$$

Diagrama de Espalhamento de Moran

Descrevendo a equação (2) em forma matricial, temos:

$$I = (Z^t W Z)/(Z^t Z), \quad (4)$$

o Diagrama de Espalhamento de Moran é uma forma gráfica adicional para visualizar o Índice de Moran. Procura-se visualizar espacialmente o relacionamento entre os valores observados Z e os valores das médias locais WZ. O diagrama é mostrado na Figura 1. O gráfico é dividido em quatro quadrantes: Q1, Q2, Q3 e Q4. Os pontos colocados nos quadrantes Q1 e Q2 indicam regiões que seguem o mesmo processo de dependência espacial das demais observações. Já os pontos colocados nos quadrantes Q3 e Q4 indicam diferentes processos de dependência espacial, ou seja, podem indicar regiões de transição entre regimes espaciais. Esse gráfico pode ser apresentado na forma de um mapa coroplético, indicando-se os quatro quadrantes com cores diferenciadas para facilitar a interpretação.

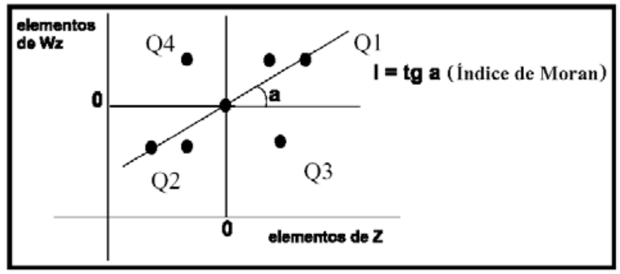

FIGURA. 1
DIAGRAMA DE ESPALHAMENTO DE MORAN.

Indicadores Locais de Associação Espacial (LISA)

Uma vez admitida a significância estatística do índice local de Moran, permite-se identificar agrupamentos de regiões com atributos semelhantes e áreas anômalas, contendo mais de um regime espacial, com significância estatística.

Para a visualização destes índices, pode ser gerado um mapa coroplético apresentando as regiões com correlação local significativamente diferente do resto das outras regiões. Normalmente, este mapa contém apenas quatro categorias, apresentando a não significância, significância em 5%, significância em 1% e significância em 0,5%.

RESULTADOS

No Censo Brasileiro de 1991 [6], o estado com o menor índice de analfabetismo era o Rio de Janeiro, com apenas 20,88%, seguido pelo Rio Grande do Sul com 21,88%. Do lado oposto, com o maior índice estava o estado de Alagoas com 57,95%, seguido pelo estado do Maranhão com 56,36%. Pode-se notar ainda que os estados das regiões norte e nordeste, com exceção de Roraima e Rondônia, estavam com percentuais de analfabetos maiores que o percentual do Brasil que era de 33,57% da população. Por outro lado, os estados das regiões Sul, Sudeste e Centro Oeste tiveram os menores percentuais de analfabetismo do país. O mapa apresentado na Figura 1 evidencia a heterogeneidade da população analfabeta como já constatado antes por Teles e Moraes [8].

No Censo Brasileiro de 2000 [5], os estados que tinham graus melhores de alfabetização continuam a possuir os melhores graus e os que possuíam os maiores graus, também continuam a tê-lo. Novamente, o Rio de Janeiro possui o mais baixo índice de analfabetismo do país com 16,97%, seguido pelo Rio Grande do Sul com 16,99%. Novamente, do lado oposto, com o maior índice continua com o estado de Alagoas com 44,08%, seguido pelo estado do Maranhão com 40,33% e as regiões Norte e Nordeste continuam com os maiores índices de analfabetismo do país, inclusive Roraima e Rondônia que apesar de terem diminuído o percentual de analfabetismo em, respectivamente, 8,20% e 10,12% ficaram com índices maiores que o do Brasil neste último Censo, que foi de 24,76%. No entanto as outras regiões permaneceram nas suas respectivas posições.

FIGURA. 2
MAPA DA POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 1991.

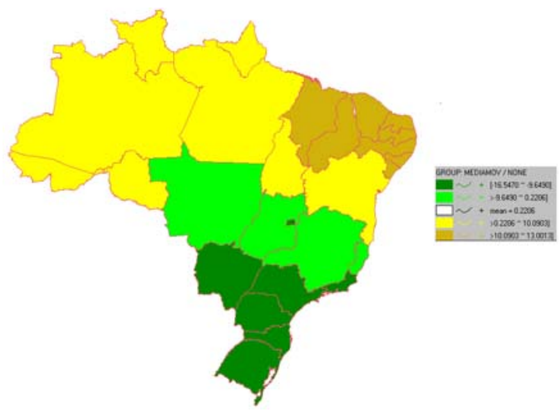

FIGURA. 3
MAPA DAS MÉDIAS MÓVEIS DA POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 1991.

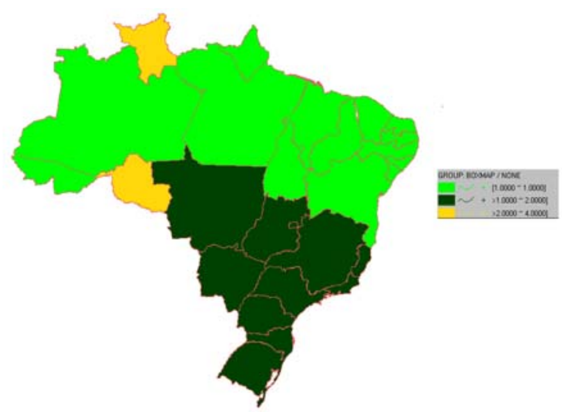

FIGURA. 4
MAPA DE ESPALHAMENTO DE MORAN PARA A POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 1991.

Analisando a variação percentual absoluta entre os Censos, constata-se que os estados que obtiveram os maiores percentuais de melhora foram os estados do Maranhão, Piauí, Paraíba e Bahia, respectivamente, com índices superiores a 15%. Por serem estados considerados em situação financeira difícil, provavelmente obtiveram apoio federal para esse salto qualitativo. Do lado oposto, os estados que obtiveram os menores percentuais de melhora foram os estados do Rio de Janeiro, São Paulo, Rio Grande do Sul, o Distrito Federal, respectivamente, com índices inferiores a 6%. Nota-se então, que os estados que estavam em melhor situação em 1991, não se empenharam tanto na solução do problema do analfabetismo na última década. Isso causa espanto, principalmente por serem os estados em melhor situação financeira no país.

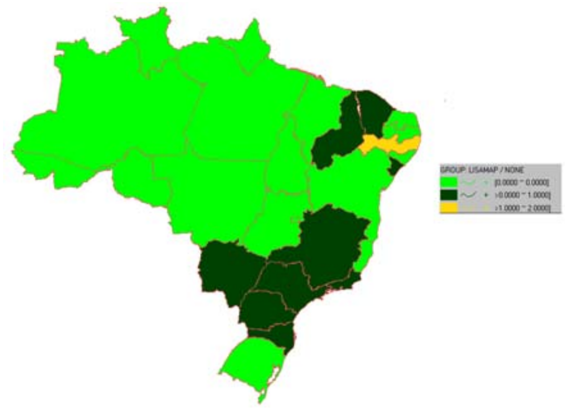

FIGURA. 5
MAPA DE INDICADORES LISA PARA A POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 1991.

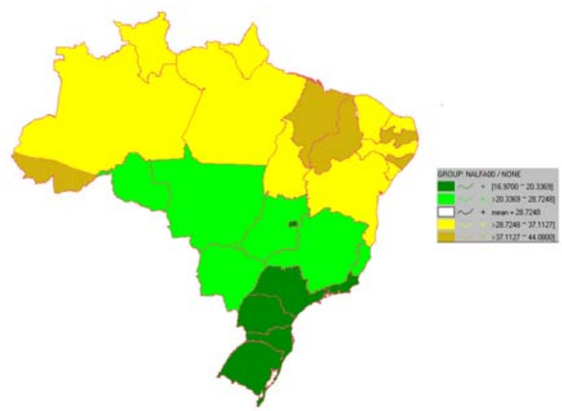

FIGURA. 6
MAPA DA POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 2000.

O Índice Global de Autocorrelação de Moran no ano de 1991 foi de 0,7282, indicando a existência de uma alta correlação espacial entre os estados do Brasil naquele ano. No ano 2000, o Índice de Moran passou a ser de 0,7151, mostrando uma pequena alteração da correlação existente.

O Mapa da Figura 2 mostra a distribuição do percentual de analfabetos do Brasil em relação ao percentual médio, no ano de 1991. Pode-se verificar que mais de 50% da população era composta por pessoas sem alfabetização, nos estados que estão em cor amarela escura. Esta área é composta pelos estados do Maranhão, Piauí, Paraíba e Alagoas. Na área em amarelo, composta pela quase totalidade da região Norte e boa parte do Nordeste, os índices de analfabetismo estão entre 39,12% e 50,90%. Observa-se também que os estados de Roraima e Rondônia possuem índices diferenciados de analfabetismo em relação à região Norte. Por outro lado os estados Rio de Janeiro, São Paulo e Distrito Federal juntamente com os estados da região Sul tiveram os menores porcentuais de analfabetos, entre 20,88% e 27,33%.

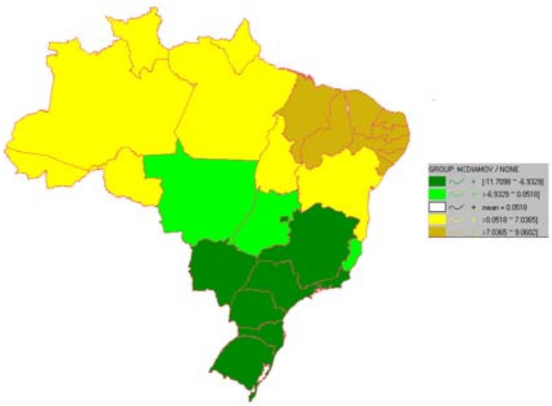

FIGURA. 7
MAPA DAS MÉDIAS MÓVEIS DA POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 2000.

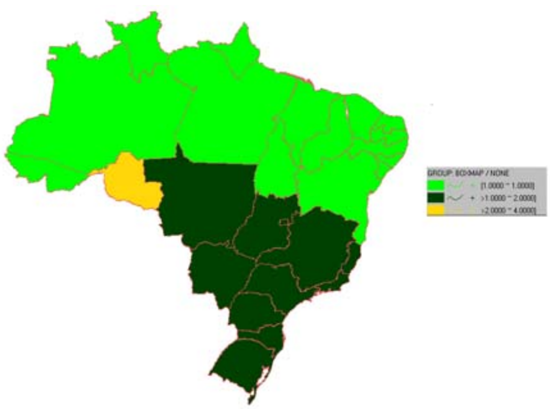

FIGURA. 8
MAPA DE ESPALHAMENTO DE MORAN PARA A POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 2000.

Utilizando-se da Média Espacial Móvel para analisar o percentual de analfabetos do Brasil, nota-se no Mapa da Figura 3, que a variação do percentual de analfabetos pode estar sendo influenciada pelas regiões políticas do Brasil. Vê-se claramente quatro regiões bem definidas. Conforme mencionado, a Média Móvel tem a vantagem de produzir uma superfície menos descontínua nos dados originais. Isso pode ser observado na Figura 3, onde os estados de Rondônia e Roraima não mais estão diferenciados em relação à região Norte. O mesmo acontece em parte da região Nordeste, com os estados do Ceará, Rio Grande do Norte, Pernambuco e Sergipe. Na região Centro-Oeste, o Mato Grosso do Sul agora se uniu ao grupo de estados do Sul e Sudeste com baixos índices de analfabetismo e o Distrito Federal encontra-se isolado em relação a essa região.

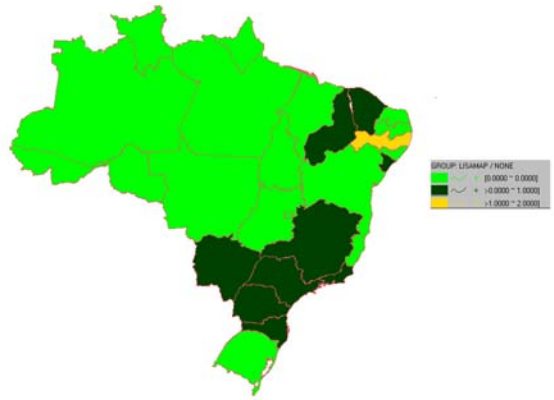

FIGURA. 9
MAPA DE INDICADORES LISA PARA A POPULAÇÃO ANALFABETIZADA DO BRASIL, SEGUNDO DADOS DO CENSO BRASILEIRO DE 2000.

O Mapa da Figura 4, Mapa do Espalhamento de Moran, onde os estados com as cores em verde claro e verde escuro estavam respectivamente no primeiro e no segundo quadrante do Diagrama de Espalhamento de Moran. Desta forma estes estados apresentaram uma associação espacial positiva. Já os estados em cor amarela, Roraima e Rondônia apresentavam uma associação espacial negativa, ou seja, não seguiam os mesmos processos de dependência espacial que os outros estados.

No Mapa da Figura 5 pode-se observar a distribuição dos Indicadores Locais de Associação Espacial para o percentual de analfabetos dos estados brasileiros em 1991. Os estados da região Norte não apresentam diferenças significativas entre si. Entre os estados do Nordeste, áreas de transição são observadas entre o Ceará e Rio Grande, Paraíba e Pernambuco, este último como transição com Alagoas. Sergipe também aparece como uma área de transição entre Alagoas e Bahia. O mapa apresenta uma área de fronteira entre os entre duas regiões definidas pelos estados do Espírito Santo, Minas Gerais e Mato Grosso do Sul. Pode-se notar o isolamento do estado do Rio Grande do Sul em relação a sua região.

No Mapa da Figura 6, tem-se a distribuição do percentual de analfabetos do Brasil em relação ao percentual médio, no ano 2000. Observa-se que os estados do Maranhão, Piauí, Paraíba, Alagoas e Acre apresentaram os maiores percentuais de analfabetos do país, entre 37,11% e 40,08%. Do lado oposto, os estados do Rio de Janeiro, São Paulo e o Distrito Federal e os estados da região Sul apresentaram os menores percentuais de analfabetos, entre 16,97% e 20,34%. Além disso, quase a totalidade da região Centro Oeste e os estados de Mina Gerais, Espírito Santo e Rondônia estavam com o percentual de analfabetos um pouco menor que o percentual médio, que foi de 28,72%.

No Mapa da Figura 7 observa-se novamente que a Média Espacial Móvel produziu uma superfície menos descontínua nos dados originais. Nota-se que os estados do Rio Grande do Norte, Ceará, Pernambuco e Sergipe não mais apresentam diferença em relação a região Nordeste, apenas com a Bahia. O mesmo ocorreu com os estados de Rondônia e Acre na região Norte. Os estados de Minas Gerais e Mato Grosso do Sul passaram a fazer parte do grupo de estados compostos por São Paulo, Rio de Janeiro, os estados da região Sul e o Distrito Federal.

Ao observar o Mapa do Espalhamento de Moran (Figura 8) para o percentual de analfabetos do Brasil, no ano 2000 verificou-se que os estados da região Nordeste e Norte, com exceção de Roraima, estão no primeiro quadrante do Diagrama de Espalhamento de Moran e os estados das regiões Centro Oeste, Sul e Sudeste estão no segundo quadrante. Com isso esses estados possuem uma associação espacial positiva, o que indica que esses estados seguem um processo de dependência espacial. O estado de Rondônia pode ser considerado como um extremo, por não estar associado espacialmente a nenhum de seus vizinhos.

A distribuição dos LISAs para o percentual de analfabetos dos estados brasileiros em 2000 pode ser observada no Mapa da Figura 9. Nota-se no mapa as seguintes áreas de transição: Santa Catarina com relação ao Rio Grande do Sul; Mato Grosso do Sul com os estados da sua região; Piauí com o Maranhão e a Bahia; Ceará com a Paraíba, Rio Grande do Norte e Pernambuco; este último como transição com Alagoas e Sergipe como transição com Alagoas e Bahia. Os estados da região Norte não apresentam diferenças significativas entre si.

Em termos comparativos, observando a evolução dos índices de Autocorrelação de Moran e a evolução dos percentuais de analfabetismo evidenciadas pelos Mapas das Figuras 2 e 6, pode-se notar que não houve uma mudança conjuntural nos quadros estaduais de analfabetismo no Brasil. Ressalvas devem ser feitas aos estados do Acre e Roraima. Ambos não acompanharam a evolução percentual dos demais estados brasileiros e se encontram diferenciados com respeito aos respectivos estados vizinhos.

Apesar dessas conclusões serem aparentemente conflitantes com a melhoria dos índices percentuais divulgados, outras informações oficiais podem vir à tona para esclarecê-las. Ribeiro [7] analisa os gastos e fontes financiadoras do Ministério da Educação (MEC) e mostra certas distorções nos investimentos do ministério. Por exemplo, em termos gerais, a partir de 1994, o governo não aplicou mais que 1,44% do PIB em educação, o que se traduz em R$ 89,31 per capita por ano. O gasto médio anual do MEC com o Ensino Fundamental entre 1993 e 1999 ficou em R$ 2.100,13 milhões com um desvio-padrão de R$ 558,25 milhões. Ao longo deste período os valores estavam em queda desde 1994 até 1997. Em 1998 os recursos aumentaram para novamente serem reduzidos em 1999. Como os valores investidos pelo MEC podem ser considerados tímidos para a gravidade do problema do analfabetismo no Brasil, fica claro que a melhoria nos índices deveu-se a uma redistribuição de recursos e não a um aumento dos investimentos em educação.

Conclusões Finais

Neste trabalho foi apresentada uma análise estatística do analfabetismo brasileiro entre os Censos de 1991 e 2000. Observou-se a diminuição significativa dos índices percentuais nacionais do analfabetismo. Porém, com a utilização de técnicas de Análise Espacial ficou evidente a permanência da estrutura do analfabetismo por estados entre os Censos.

Portanto, apesar da melhoria evidenciada pelos índices globais, o Brasil apresenta a mesma distribuição espacial no analfabetismo, preservando as desigualdades regionais que deveriam ter sido amenizadas. De um modo geral, alguns estados não melhoraram seus índices na proporção de seus vizinhos, como o Rio de Janeiro, São Paulo, Rio Grande do Sul e o Distrito Federal. Isso provavelmente se deve a uma redistribuição dos recursos do MEC entre os estados, visto que o volume de recursos total sofreu bruscas reduções durante o período e fecharam em 1999 em patamar inferior ao de 1994. Essa redistribuição foi suficiente para diminuir os índices do analfabetismo brasileiro, ainda que não tenha sido suficiente para alterar a distribuição espacial do mesmo.

Segundo o Banco Interamericano de Desenvolvimento (BIRD), mantendo-se constante os fatores de capital, terra e trabalho, o aumento de um ano na média educacional da população economicamente ativa determina um incremento de 5,5% na taxa de crescimento do PIB [9]. Para melhorar a baixa média educacional brasileira, obviamente valores compatíveis devem ser investidos em educação.

SESHET-S: Um Sistema de Monitoria Virtual para o Ensino a Distância de Estatística

Hérico Gouveia de Souza[1], e Ronei Marcos de Moraes[2]

Resumo *— Este artigo descreve a plataforma de monitoria virtual denominada SESHET-S e a implementação de um módulo adicional para o ensino de Amostragem. Esse sistema modela o conhecimento em módulos independentes de conhecimento usando regras "fuzzy". A resposta a uma dada consulta ao sistema é fornecida levando-se em consideração todas as possíveis respostas e também apontando o valor percentual das suas possibilidades. O novo módulo de Amostragem contém o conhecimento dos diversos tipos clássicos de amostragem e inclui também o cálculo do tamanho da amostra para a amostragem aleatória simples usando uma média ou uma proporção*

Palavras-chave — Monitoria Virtual, Sistemas Especialistas, Ensino a Distância, Ensino de Estatística.

INTRODUÇÃO

A profusão de análises estatísticas inadequadas no meio científico mostra a falta de um cuidado maior na manipulação de dados de pesquisa. Vários trabalhos publicados em periódicos de renome ou não, trazem a falta patente de um pesquisador da área de estatística, com suas análises insuficientes e conclusões seriamente prejudicadas. No meio comercial e empresarial, tal fato também ocorre e pesquisas de opinião no Brasil e em outros países trazem vícios de concepção que levam a conclusões no mínimo não-convencionais. Estas deficiências originam-se no aprendizado deficiente da estatística ministrada no ensino médio e superior, tanto pelo fato das ementas destas disciplinas não atenderem a cada curso especificamente, quanto pela falta de uma estrutura de apoio ao ensino que leve o aluno a um aprendizado mais profundo das técnicas estatísticas. Desta forma, a maioria dos profissionais sabe da existência da ciência, porém não a conhecem na profundidade suficiente para que ela lhes seja útil realmente. [12].

Dada esta realidade e com o advento do Ensino à Distância, onde ensinamos nossos alunos por correio, televisão e recentemente através de redes de computadores (notadamente pela Internet), observamos um sério problema: se o aprendizado nas disciplinas de estatística já é insuficiente no ensino presencial, como resolver as dúvidas de um estudante à distância? Na maioria das vezes, não é possível colocar um professor em contato direto com o aluno.

No futuro, o ensino à distância reduzirá as limitações geográficas e os cursos atenderão a um grande número de estudantes. Esses estudantes necessitarão de orientadores e monitores para responder às suas questões e dúvidas [15]. Dentro desta ótica, um sistema especialista acoplado a um sistema de análise seria bem-vindo no sentido de orientar o correto uso das suas ferramentas, bem como no ensino delas, como Coob [3] sugere. Também seria interessante que esse sistema possa ensinar ao usuário os passos de uma análise e guiá-lo na sua execução, seguindo a tendência de Giraud [5].

Em várias áreas do conhecimento humano, os sistemas especialistas são utilizados para o auxílio em tomada de decisões: seja na medicina, economia, indústria, etc. As regras são usadas para expressar o conhecimento humano sobre um assunto e essas regras podem ser tratadas por vários tipos de lógica, como a lógica clássica, a lógica modal, a lógica *fuzzy*, etc de acordo com o tipo de aplicação [17].

Sob o ponto de vista didático e estatístico, não existe uma ferramenta de ensino que una um sistema especialista dedicado ao ensino a um "software" estatístico. Nem mesmo os "softwares" comerciais mais utilizados como SAS®, SPSS®, Statistica® ou SPlus®, têm um sistema especialista para auxiliar o usuário na decisão sobre qual método é adequado ao seu problema. Estes sistemas estatísticos são capazes de análises complexas, mas não limitam ou guiam os usuários nas suas ações. Assim, esses "softwares" não podem auxiliar o usuário no uso de uma técnica em detrimento de outra e nem mesmo podem guiá-lo a não utilizar uma técnica equivocada em sua análise.

Uma possível solução para este problema seria a construção de um sistema especialista com conhecimento específico sobre "como ensinar" um determinado assunto. Assim, o estudante poderia interagir com este sistema para aprender e solucionar suas dúvidas. No entanto, esse sistema não pode ser apenas um sistema especialista para tomada de decisões, como os mencionados anteriormente; ele deve possuir características especiais para simplificar o seu uso e ser amigável, já que a sua utilização será feita por pessoas inexperientes na área.

Moraes e Zuffo [12] propuseram uma arquitetura inteligente, usando lógica *fuzzy* para aplicações em Ensino à Distância com características específicas para atender a área

[1] Hérico Gouveia de Souza, Aluno Voluntário de Iniciação Científica. Departamento de Estatística, Universidade Federal da Paraíba, Cidade Universitária s/n CEP 58.051-900 João Pessoa – PB - Brasil, tel.: +55 83 216-7075, herico_gouveia@uol.com.br

[2] Ronei Marcos de Moraes, Departamento de Estatística, Universidade Federal da Paraíba, Cidade Universitária s/n CEP 58.051-900 João Pessoa – PB - Brasil, tel.: +55 83 216-7075, ronei@de.ufpb.br

de ensino, como: possibilidade para interpretar respostas vagas e imprecisas (como por exemplo: “Eu não sei”, ou “Deve ser...”); possibilidade para apresentar várias possíveis soluções para uma dúvida e apontar deficiências do conhecimento do estudante. Esta arquitetura foi denominada: *Monitor Virtual* dada a sua similaridade com a função exercida pelos monitores no ensino tradicional [12]. Foi proposta também uma aplicação desta arquitetura na construção de um sistema de apoio ao ensino à distância de Estatística, denominado SESHET-S [11].

A partir da implementação desta arquitetura o SESHET-S, em sua versão original, cobria os tópicos de Análise Exploratória de Dados [16], Noções de Probabilidade [8], Inferência Estatística Paramétrica [9], Inferência Estatística Não-paramétrica [7], Análise de Regressão e Análise de Variâncias [14].

Com este leque de assuntos o *software* se apresenta como uma ferramenta bastante útil para o esclarecimento de dúvidas pertinentes aos mesmos. Embora estes assuntos cubram uma quantidade significativa de análises, vários tópicos avançados ainda não foram implementados, como a Amostragem que é a base para os procedimentos de coleta de dados. Este trabalho propõe o aperfeiçoamento do SESHET-S e a implementação de um módulo que trate deste tema com o seguinte conteúdo: Amostragem Aleatória Simples, Amostragem Estratificada, Amostragem Sistemática, Amostragem por Conglomerados e Determinação do Tamanho de Amostra [2]. Com esse conteúdo, o sistema SESHET-S poderá se útil para um número maior de disciplinas e estudantes.

Este artigo está assim disposto: na próxima seção apresenta-se uma revisão da metodologia empregada na construção do SESHET-S, a qual está sendo utilizada novamente para a adição deste novo módulo. Na seção posterior, alguns resultados serão apresentados e por fim, a última seção apresenta as conclusões finais.

METODOLOGIA

Os sistemas especialistas tratam problemas que são usualmente resolvidos por especialistas humanos [13]. Estes sistemas trabalham sobre o conhecimento de um determinado domínio, de modo similar ao ser humano, conhecimento este que é codificado para ser tratado pelo computador. O conhecimento é geralmente caracterizado por um grupo de regras e fatos. As regras são a tradução do conhecimento de um especialista e os fatos podem ser adquiridos inicialmente ou posteriormente, durante o processo de dedução [1]. Usando regras e fatos, novos fatos são obtidos. Para obter novos fatos, uma ou mais formas de raciocínio podem ser usadas. Em geral, os sistemas especialistas podem mostrar ao usuário como deduzir algo no processo de decisão e como novos conhecimentos podem ser inseridos na base de conhecimento. Além disso, podem checar se um novo conhecimento pode gerar conflito com a base de conhecimento previamente armazenada.

Usualmente, os sistemas especialistas respondem a melhor solução lógica possível para a consulta do usuário e sistemas especialistas na área de estatística não são diferentes. Como a principal aplicação é o ensino, a base de conhecimento deste sistema deve ser capaz de tratar informação incompleta ou vaga. O usuário será um estudante e ele poderá não conhecer bem o assunto e por essa razão, utiliza-se a lógica *fuzzy* [6, 20]. Essa lógica combina regras e fatos usando um modo de raciocínio denominado raciocínio aproximado [4], podendo tratar respostas incompletas e apontar várias soluções lógicas para um problema e quantificá-las [10]. Para cada resposta, o sistema deverá mostrar as condições para sua aplicação e uma medida de possibilidade [19] para ela no contexto apresentado. Dependendo da qualidade da consulta processada pelo usuário, o sistema pode concluir que o mesmo deve estudar alguns fundamentos teóricos, apontando tópicos e sugerindo bibliografia correspondente, sem lhe dar uma resposta final a sua consulta, como faria um professor tradicional.

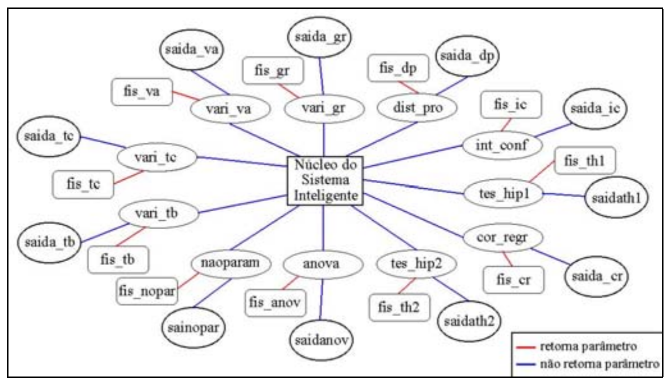

FIGURA. 1
ESTRUTURA MODULAR DO SISTEMA ESPECIALISTA SESHET-S.

Para combinar três propriedades importantes da Engenharia de Software que são: modularidade, facilidade de manutenção e facilidade de implementação de novas rotinas, o sistema foi implementado de acordo com a estrutura modular mostrada na Figura 1. O núcleo do sistema contém apenas as chamadas para sub-rotinas que implementam cada um dos tópicos abordados pelo sistema e uma parte da interface de comunicação com o usuário. Dentro das sub-rotinas (vari_va, vari_tc, dist_pro, etc), uma segunda parte da interface de comunicação com o usuário atua na coleta das informações relevantes e as transfere para uma rotina de manipulação do conhecimento. Essas rotinas de manipulação (fis_va, fis_tc, fis_dp, etc) apenas verificam a compatibilidade de cada possível resposta com os dados de entrada e retorna um vetor de possibilidades à rotina que a iniciou. Esta comunicação que retorna um parâmetro está denotada no diagrama pelas ligações em vermelho. Esta arquitetura possibilita um acesso rápido ao conjunto de regras envolvidas em cada módulo evitando assim, interações desnecessárias do sistema. Outra vantagem é a possibilidade de evitar que problemas de manutenção em um dado módulo venham a se propagar pelo sistema.

Para implementar essa arquitetura, foi utilizado o *software* Matlab que possui uma *toolbox* para o manuseio do conhecimento dado por regras *fuzzy*, as quais manipulam o conhecimento modelando conjuntos *fuzzy* [18]. Além disso, o Matlab também possui uma *toolbox* de estatística que embora não tenha sido utilizada na construção do sistema foi um dos atrativos para a sua utilização em futuras versões.

O conjunto de regras e funções de pertinência necessárias à implementação do conhecimento foi fornecido por um especialista humano. Esse conjunto de regras e seus respectivos assuntos estão descritos na Tabela 1, onde também podem ser visualizadas as disciplinas oferecidas pela UFPB que poderão utilizar o sistema.

TABELA 1
MÓDULOS DO SISTEMA SESHET-S COM SEUS RESPECTIVOS NÚMEROS DE REGRAS, ASSUNTO E A QUE DISCIPLINA SE DESTINA.

Disciplinas a que se destina	Assunto	Módulos implementados	Número de regras
Cálculo das Probabilidades e Estatística I	- Tabelas de Freqüência	vari_tb	22
	- Medidas de Tendência Central	vari_tc	46
	- Med. de Variabilidade	vari_va	45
Estatística Vital	- Gráficos	vari_gr	15
	- Distribuição de Probabilidade	dist_pro	23
Estatística III	- Intervalo de Confiança	int_conf	36
	- Testes de Hipóteses	tes_hip1	48
	- Correlação e Regressão	cor_regr	32
Estatística IV	- Testes de Hipóteses	tes_hip2	80
	- Análise de Variâncias	Anova	32
	- Métodos Não-paramétricos	Naoparam	35
		Total	414

FONTE: DADOS DO SISTEMA SESHET-S NA SUA VERSÃO ATUAL.

Atualmente, as disciplinas apresentadas na Tabela 1 e suas variações (disciplinas específicas com ementa ligeiramente menor) cobrem cerca de 40% das disciplinas oferecidas pelo Departamento de Estatística da UFPB, ou seja, cerca de 1000 alunos podem se beneficiar deste sistema a cada semestre letivo.

Com a implementação do novo módulo, duas novas disciplinas e cerca de 200 novos alunos irão se somar a esses potenciais usuários, elevando o percentual a valores próximos a 50% das disciplinas oferecidas pelo Departamento. O módulo sobre Amostragem segue essa arquitetura e traz um conteúdo sobre [2]:

- Amostragem Aleatória Simples - é o processo de amostragem em que as combinações de *n* diferentes elementos, dos *N* que compõem a população, possuem igual probabilidade de vir a ser a amostra efetivamente sorteada;
- Amostragem Estratificada - é o processo de amostragem no qual a população constituída por *N* elementos é previamente dividida em grupos distintos ou mutuamente exclusivos, que são denominados estratos, daí o seu nome. Dentro de cada extrato podemos extrair as amostras segundo os critérios da amostragem aleatória simples.
- Amostragem Sistemática - é o processo de amostragem no qual se considera os *N* elementos da população numerados de 1 até *N*, em alguma ordem. Para selecionar uma amostra de *n* unidades, tomamos uma unidade aleatoriamente das primeiras *k* unidades e a partir desta, a cada *k* unidades sucessivamente.
- Amostragem por Conglomerados - é o processo de amostragem em que, os elementos da população fazendo parte de grupos, são sorteados alguns desses grupos para comporem a amostra.
- Determinação do Tamanho de Amostra - Mostrar a metodologia de cálculo do tamanho da amostra para a amostragem aleatória simples nos casos de se estimar uma média ou uma proporção [2]. No caso da média, temos dois casos a se considerar: o primeiro, quando se conhece a variância populacional e o segundo, quando ela não é conhecida. No caso da proporção, o cálculo depende do próprio parâmetro a ser estimado [2] e por isso também temos dois casos a considerar: o primeiro quando temos alguma informação sobre a proporção a ser pesquisada e o segundo, quando nenhuma informação é disponível.

A limitação do novo módulo a esse escopo específico é devido às ementas das disciplinas a serem atendidas. É sabido que outros tópicos poderiam também ser abordados, como por exemplo, o sorteio das amostras, os estimadores e seus diferentes tipos, a determinação do tamanho da amostra para os outros tipos de amostragem, os diferentes tipos de conglomerados e a correção para populações finitas, entre outras, porém estes tópicos pertencem a disciplinas mais avançadas no estudo da Amostragem. Futuramente, pretendemos ampliar o módulo de amostragem para atender a essas disciplinas mais avançadas, tanto para atender melhor aos alunos de graduação, como aos de pós-graduação.

RESULTADOS

Da concepção original do sistema a versão atual, o mesmo passou por várias melhorias e acréscimos no conjunto de regras que foram dando origem a novas versões. Estas melhorias permitiram chegar aperfeiçoar o conjunto de regras para melhor tratar formas específicas de dúvidas e também a interface, onde são utilizadas janelas com perguntas de múltipla resposta, como pode ser visto na Figura 2. Atualmente o sistema está na versão pré-release SESHET-S versão 0.4 e está em fase de testes de utilização por algumas turmas. Estes testes visam a evolução do sistema, correções de problemas e imperfeições e ainda a adaptações gráficas para facilitar a sua utilização e torná-lo mais amigável ao usuário. Ao mesmo tempo, novos conhecimentos e módulos estão sendo inseridos, aprimorando o sistema e tornando-o mais útil para os alunos e professores das disciplinas mencionadas anteriormente.

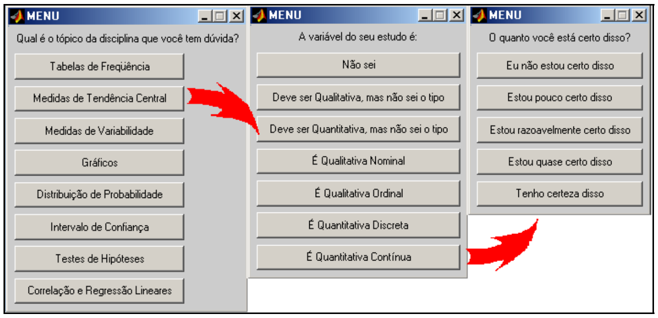

FIGURA. 2
MENU PARA ENTRADA DE INFORMAÇÕES NO SISTEMA SESHET-S.

O usuário passa as informações sobre a sua dúvida através de um sistema de menus. Esses menus direcionam o sistema para um dos módulos de conhecimento específico do SESHET-S. O sistema quantifica a certeza do aluno em cada uma das suas informações e ao final coloca todas as possíveis respostas em uma nova janela, bem como as possibilidades de ocorrência de cada uma delas, como pode ser observado na Figura 3. Devemos notar que a medida de possibilidade [19], diferentemente da medida de probabilidade [8], não precisa ter uma soma total fechada em 100%.

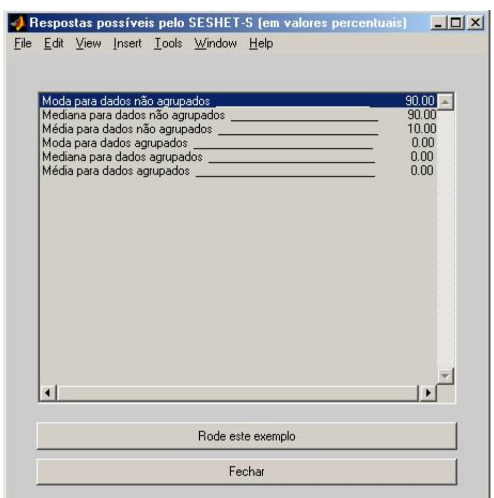

FIGURA. 3
RESPOSTAS POSSÍVEIS PARA UMA DADA CONSULTA NO SISTEMA SESHET-S.

Para ilustrar o processo de consulta, tomemos como exemplo seqüência dada pelas Figuras 2 e 3. Na Figura 2, no primeiro Menu, o aluno selecionou uma dúvida no tópico "Medidas de Tendência Central". No segundo Menu, a variável do estudo é declarada como "É Qualitativa Ordinal" e no terceiro Menu, ele responde que "Estou quase certo disso". O sistema continua a questionar o aluno através de Menus, análogos ao da Figura 2 para definir melhor o escopo da resposta e as possibilidades de cada uma delas. Ao final dessas interações com o aluno, o sistema exibe todas as respostas possíveis para o tipo de questão e as possibilidades de cada resposta, inclusive as respostas não possíveis. O objetivo na menção das respostas não possíveis é mostrar ao aluno também os caminhos que não devem ser seguidos. Na Figura 3, o aluno receberia como resposta a sua consulta que a possibilidade para a resposta "Moda para dados não agrupados" é de 90%, bem como a da "Mediana para dados não agrupados". A "Média para dados não agrupados" possui uma possibilidade de apenas 10%. As demais respostas para as mesmas medidas para dados agrupados possuem possibilidade zero. Então o aluno pode perceber que as Medidas de Tendência Central: Moda e Mediana podem se aplicar ao seu caso com alta possibilidade. Com uma baixa possibilidade, a Média também poderia se aplicar a esse caso. A imprecisão da resposta deve-se a imprecisão do questionamento do aluno, dado que ele não tem certeza sobre o tipo da variável, ainda que aponte que ela possa ser Qualitativa, em um primeiro momento. O sistema nesse caso aponta direções para o aluno, mas não esclarece definitivamente a dúvida do aluno, assim como um professor real também não poderia fazê-lo. Um professor real necessariamente diria: "Você precisa saber qual é o tipo de variável para que eu possa esclarecer quais tipos de Medidas de Tendência Central se aplicam ao seu caso".

CONCLUSÕES FINAIS E TRABALHOS FUTUROS

Este trabalho descreve a plataforma de monitoria virtual denominada SESHET-S e a implementação de um módulo adicional para o ensino de Amostragem. O conteúdo deste módulo inclui as técnicas clássicas de Amostragem, e a forma de se calcular o tamanho da amostra para a amostragem aleatória simples.

Esse sistema pode apoiar o ensino à distância e também pode ser aplicado como um reforço no ensino presencial. Auxiliado pelo sistema especialista *fuzzy*, o usuário pode ser treinado em várias situações a encontrar a melhor resposta para a sua consulta ou confrontar suas conclusões com as conclusões apresentadas pelo sistema especialista. Este sistema pode também verificar o conhecimento do estudante sobre algum assunto específico e assuntos correlatos.

Vale notar que em termos de arquitetura, esta é suficientemente genérica para ser aplicada ao ensino à distância de outros tópicos, relacionados ou não com a Estatística.

O sistema SESHET-S estará brevemente disponível para *download* via Internet a todos os alunos, em uma versão compilada independente do *software* Matlab. O próprio Matlab permite a compilação em separado de sistemas criados em sua plataforma. Assim, os alunos não necessitarão de ter uma licença desse *software* instalado para poder utilizar o SESHET-S. Além da facilidade de utilização para os alunos, essa solução também permite que o sistema continue sendo desenvolvido sob a plataforma Matlab. Estuda-se também uma possível versão em linguagem Java que poderia ser operada pela Web, diretamente do servidor do Departamento de Estatística da UFPB.

Futuramente, pretendemos analisar a contribuição desse sistema ao ensino de estatística, comparando-se turmas que utilizem o sistema e que não o façam. Várias outras particularidades no estudo da amostragem poderão também ser abordadas, para tornar esse módulo um subsistema maior, dedicado ao estudo de técnicas mais avançadas dos processos de Amostragem.

O SISTEMA DE COTAS NO INGRESSO DOS CURSOS DE ENGENHARIA DA UERJ

Evandro Mendes da Silva[1] ,Nival Nunes de Almeida[2], Maria Luiza Fernandes Velloso[3] e Maria Eugenia Gouvêa[4]

Resumo — A UERJ (Universidade do Estado do Rio de Janeiro) está reservando para o ingresso nos cursos de graduação 50% de suas vagas a estudantes de origem de escolas mantidas pelo poder público e até 40% para os negros e pardos. Neste sistema de cotas, que está sendo implantado no vestibular deste ano para todos os *campi*, envolve também os cursos das Engenharias da UERJ que estão distribuídos em três *campi*: na cidade do Rio de Janeiro-a Faculdade de Engenharia, no médio Paraíba-a Faculdade de Tecnologia e na região serrana de Nova Friburgo-o Instituto Politécnico. Como exemplo do volume de estudantes envolvidos, pode-se citar o número de inscritos no vestibular de 2001, quando ainda não existia o sistema de cotas, em que o campus da UERJ do Rio de Janeiro teve 5.316 candidatos para um total de 460 vagas nos cursos de engenharia Elétrica, Cartografia, Civil, Mecânica, Química e Produção. Sendo a UERJ uma instituição com um grande contigente de estudantes, este sistema de cotas se torna impactante para todo o sistema universitário. Assim, o objetivo deste trabalho é expor as leis que instituíram este sistema de cotas e suas repercussões no ensino de Engenharia na UERJ.

Termos Índice — Minorias em Engenharia, Ensino de Engenharia, Educação Superior.

I-INTRODUÇÃO

O presente trabalho apresenta alguns resultados parciais dos concursos de seleção para a graduação da UERJ. Estes resultados podem contribuir como subsídios no delineamento do perfil do estudante que ingressará na UERJ no primeiro e segundo semestres de 2003. Nesses concursos há uma cota de vagas específica para estudantes de escolas públicas e/ou autodeclarados negros ou pardos.

Os estudantes oriundos de escolas mantidas pelo poder público podem optar entre o vestibular SADE/2003 e o vestibular Estadual/2003 para ingressar nos cursos de graduação da UERJ. No Sistema de Acompanhamento do Desempenho dos Estudantes do Ensino Médio (SADE) somente estudantes que cursaram integralmente os ensinos fundamental e médio em instituições mantidas pelo poder público localizadas no Estado do Rio de Janeiro podem fazer este concurso, conforme disposto na Lei Estadual nº 3.524, de 28 de dezembro de 2000 . Já o vestibular Estadual/2003 é aberto para estudantes de escolas públicas e particulares.

Nesses concursos há uma parcela de 2.485 vagas para UERJ reservadas ao vestibular SADE e 2.485 vagas para o vestibular Estadual. Do total de vagas destes concursos há uma reserva de 40% de vagas destinadas ao candidatos que se declararem negros ou pardos no momento da inscrição [3].

A classificação será feita obedecendo a ordem descrente do total de pontos. Para o cálculo do percentual de 40% dos candidatos autodeclarados negros e pardos será considerado, inicialmente, os candidatos do vestibular SADE. Se este percentual não for alcançado sua complementação será feita com os candidatos do vestibular Estadual [1].

II - SADE – SISTEMA DE ACOMPANHAMENTO DO DESEMPENO DOS ESTUDANTES

O SADE é um concurso realizado em duas etapas. A primeira, denominada de Exame de Qualificação, é uma prova objetiva e de múltipla escolha em que se procura avaliar as competências e habilidades de avaliação, análise, interpretação e observação do candidato. Neste exame será considerado aprovado e poderá fazer o Exame Discursivo, quem se enquadrar entre os conceitos A, B, C e D. O conceito A representa um número de acertos maior do que 70% das questões. O conceito B significa um número de acertos maior do que 60% e igual ou menor do que 70% das questões. Para o conceito C, o número de acertos deve ser maior do que 50% e igual ou menor do que 60% das questões. No conceito D, o número de acertos deve ser maior do que 40% e igual ou menor do que 50% das questões. Serão considerados reprovados os candidatos que tiverem um número de acertos igual ou menor do que 40% das questões.

A segunda avaliação é o Exame Discursivo que é formado por uma prova de língua portuguesa com redação para todos e mais três provas de disciplinas específicas por grupo de carreiras afins. Esse exame procura avaliar as competências e habilidades já avaliadas no Exame de Qualificação acrescida da capacidade de criação. Este exame é igual tanto para os candidatos do vestibular SADE/2003 quanto para o vestibular Estadual/2003.

III – RELAÇÃO CANDIDATO/VAGA

No processo de seleção aos cursos de graduação da UERJ, houve um número maior de candidatos no vestibular Estadual/2003 para as engenharias do que no SADE/2003. Estes dados podem ser observados na TABELA I, que mostra o número de inscritos e a relação candidato vaga para o SADE e o vestibular Estadual dos cursos de Engenharia.

Um caso interessante extraído da tabela, é a relação candidato/vaga de 0,75 para engenharia cartográfica no SADE e de 5,9 no vestibular Estadual. No SADE, para esta habilitação, o candidato cumprindo os requisitos mínimos de aprovação ele terá, praticamente, uma vaga no curso de Engenharia .

TABELA I
RELAÇÃO CANDIDO/VAGA ESTADUAL E SADE 2003

	Estadual			SADE		
	Total Inscritos	Vagas	Rela. C/V	Total Inscritos	Vagas	Rela. C/V
Eng. Cartográfica	118	20	5,9	15	20	0,75
Eng. Civil	552	60	9,2	118	60	1,97
Eng. Produção	373	30	12,43	33	30	1,1
Eng. Elétrica	1.188	110	10,8	257	110	2,34
Eng. Mecânica	355	30	11,83	63	30	2,1
Eng. Química	614	40	15,35	94	40	2,35

Outra diferença acentuada na relação candidato/vaga é no curso de engenharia de produção que possui 373 candidatos concorrendo a 30 vagas no vestibular Estadual e no SADE são 33 candidatos para o mesmo número de vagas.

IV – NEGROS E PARDOS

A porcentagem de candidatos a engenharia da UERJ que se declararam negros ou pardos é maior no vestibular SADE 2003 que no Estadual 2003 como se pode ver na TABELA II.

TABELA II
PERCENTAGEM DE NEGROS/PARDOS AUTODECLARADOS

	Estadual			SADE		
	Tot. Insc.	Auto Declara-do	% Negros/ pardos	Tot. Insc.	Auto Declarado	% Negros/ pardos
Eng. Cartográfica	118	31	26,27%	15	6	40%
Eng. Civil	552	87	15,76%	118	47	39,83%
Eng. Produção	373	50	13,40%	33	12	36,36%
Eng. Elétrica	1.188	229	19,28%	257	137	53,31%
Eng. Mecânica	355	57	16,06%	63	29	46,03%
Eng. Química	614	116	18,86%	94	37	39,36%

V – RESULTADO DO EXAME DE QUALIFICAÇÃO

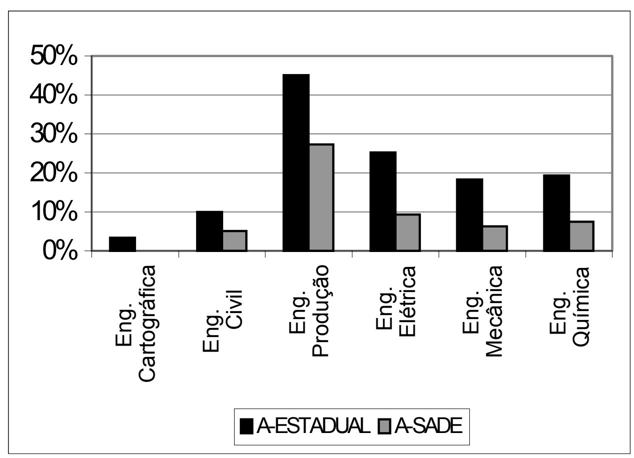
O resultado geral do Exame de Qualificação mostrou que os candidatos do vestibular Estadual apresentaram melhor desempenho quando comparados aos do SADE. Esta constatação pode ser observada na Tabela III, que mostra o resultado do Exame de Qualificação para o vestibular SADE/2003 e Estadual/2003.

TABELA III
RESULTADOS DO EXAME DE QUALIFICAÇÃO

	ESTATUAL 2003	SADE 2003
Conceito	%	%
A	6,39%	2,27%
B	13,68%	6,01%
C	22,31%	14,46%
D	30,90%	33,04%
E	26,72%	44,21%
TOTAL	100%	100%

No caso específico dos cursos de engenharia, os candidatos tiveram desempenho semelhante ao resultado geral. Esses resultados podem ser observados nos gráficos I, II, III e IV que apresentam a porcentagem de aprovados com conceitos A, B, C e D para os cursos de Engenharia Cartográfica, Civil, Produção, Elétrica, Mecânica e Química.

GRÁFICO I
PORCENTAGEM DE APROVADOS COM COMCEITO A



Analisando os gráficos se constata que é maior a porcentagem de candidatos do vestibular Estadual aprovados com A e B quando comparado ao vestibular SADE. O SADE tem um porcentagem maior de aprovados com conceito D. Com conceito C há algumas habilitações das engenharias em que existem uma porcentagem maior de aprovados do SADE.

GRÁFICO II

PORCENTAGEM DE APROVADOS COM COMCEITO B

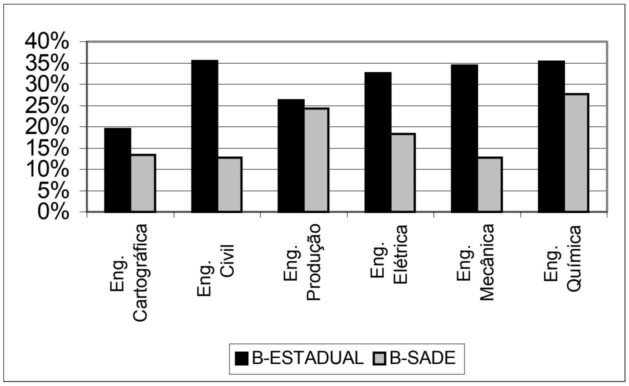


GRÁFICO III

PORCENTAGEM DE APROVADOS COM COMCEITO C

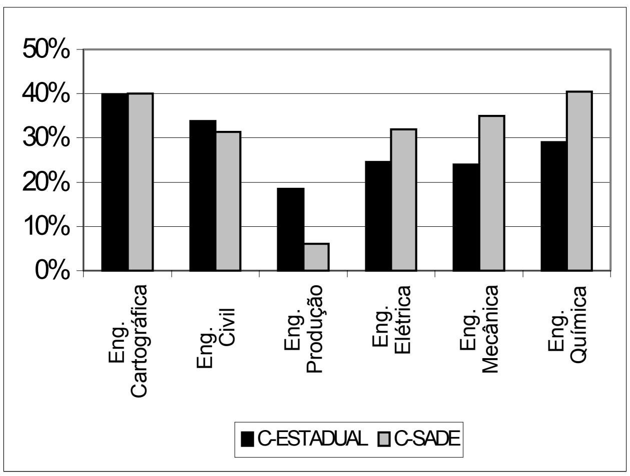

GRÁFICO IV

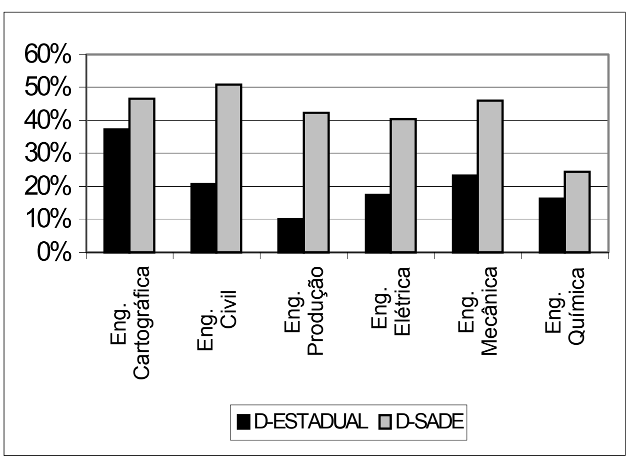
PORCENTAGEM DE APROVADOS COM COMCEITO D



VI – CONSIDERAÇÕES FINAIS

Comparando a relação candidato vaga dos concursos de acesso aos cursos de graduação da UERJ com os resultados do Exame de Qualificação, observa-se que os candidatos do concurso menos disputado, que é o SADE, apresentaram um desempenho menor que os candidatos do vestibular Estadual.

Até o presente momento, não temos os resultados do Exame de Discursivo. No entanto, considerando que esses resultados possam refletir nos resultados das provas discursivas, no ano de 2003, os cursos de engenharia poderão ter alunos com níveis diferentes de capacidades e habilidades. Umas das preocupações dos autores é que essa diferença possa implicar em desempenhos diferentes dos estudantes após a entrada na universidade. Por exemplo, se estes universitários forem tratados sem distinção é possível que aumente a evasão escolar.

Com relação a evasão, tradicionalmente na UERJ, os alunos ficam desmotivados com o considerável índice de reprovação nas disciplinas da parte comum do curso, como os cálculos e as físicas. Essas reprovações contribuem no índice de desistência dos estudantes.

Assim, para não aumentar a evasão, os autores concordam que é importante que a UERJ se prepare para receber os novos universitários, principalmente os oriundos do SADE, criando condições que melhorem a relação ensino-arprendizagem durando sua permanência na universidade.

Com esse objetivo de melhorar essa relação, há atualmente uma comissão da Sub-Reitoria de Graduação desenvolvendo um projeto que permitirá a aquisição de mais livros para as bibliotecas e apoio ao estudante. Isto se dará tanto do ponto de vista pedagógico quanto financeiro. Como exemplo, está sendo analisada a possibilidade de fornecer bolsas aos alunos carentes.

Sendo objetivo do legislador democratizar o acesso às instituições públicas estaduais de ensino superior, o SADE realmente aumenta as chances dos estudantes das escolas públicas. Porém, cabe a Universidade do Estado do Rio de Janeiro atualizar o projeto pedagógico para motivar todos os alunos que ingressarão em seus cursos. Assim, a UERJ estará contribuindo com a sua permanência na instituição.

Laboratório Virtual Colaborativo para Experiências em Eletrônica

Bianchi Serique Meiguins[1,2], *Breno Serique Meiguins*[1], Luiz Affonso Guedes[1], Marcos Paulo Alves de Souza[1], Marcelo de Brito Garcia[1], *Rosevaldo Dias de Souza Júnior*[2].

Abstract: *The aim of this article is to present the multi-user version of LVEE (Virtual Laboratory for Electronic Experiences), that it is a three-dimensional environment for simulation of electronic experience. The changes, not only make possible the users to share the same environment, but they also include innovations in the interface to increase the scene realism. The virtual world of LVEE was inspired in electric engineering laboratories of UFPA. The LVEE interface allows the construction of circuits using 3D components and permits local or remote circuit simulation. It makes use of the Virtual Reality Modeling Language (VRML), External Authoring Interface (EAI), JAVA language, SPICE (Simulation Program with Integrated Circuit Emphasis) and Microsoft Access 2000.*

Keyword: *Collaborative Virtual Environment of Teaching, Electrical Circuits, VRML, JAVA*

1. Introdução

A Realidade Virtual (RV), como tecnologia, tem fornecido novos meios para melhorar a interface e a interação com os sistemas computacionais, permitindo que os usuários se envolvam no ambiente através de seus sentidos, aumentando o realismo. Com isso, as experiências adquiridas na execução de alguma tarefa se tornam mais duradouras, como no mundo real [1] [2].

Contudo, a preocupação principal não é só melhorar a interação humano-computador, mas melhorar a interação humano-humano, usando o computador como meio de comunicação. A partir dessa premissa e utilizando o poder da RV, nasceram os Ambientes Virtuais Multiusuários (AVMU) [3], ambientes tridimensionais gerados por computador que permitem que os usuários possam se encontrar, compartilhar o ambiente e informações. A grande motivação para o desenvolvimento de AVMUs está no exponencial crescimento da área e no elevado potencial deste tipo de aplicação para qualquer área do conhecimento. Além disso, a grande maioria dos ambientes multiusuários se apresenta numa forma totalmente bidimensional, causando algumas restrições aos usuários, tais como: a falta da noção de presença de outros usuários, ou de um ambiente mais contextualizado para as tarefas, ou de um ambiente mais próximo do real para o desenvolvimento das tarefas, falta de novas formas de comunicação, entre outros.

Devido a essas características, os AVMUs são ferramentas excelentes para a realização de atividades colaborativas e cooperativas. As habilidades sociais dentro de um espaço tridimensional (mundo real) são inerentes ao ser humano quando inserido em uma comunidade, portanto, nada mais natural que cooperar ou colaborar em um ambiente com características semelhantes. Com isso, pode-se utilizar o conceito de Ambiente Virtual Colaborativo (AVC), que é um AVMU que permite que várias pessoas possam interagir através de ambiente virtual tridimensional para atingir um objetivo comum.

O projeto descrito por este artigo faz uso da tecnologia de RV não imersiva, para melhorar a interface e a interação computacional e atingir uma grande quantidade de usuários, uma vez que usa periféricos convencionais, e a própria Internet como meio de comunicação, em função dos avanços tecnológicos que vem sofrendo, permitindo assim maior qualidade e confiabilidade aos AVC.

Este projeto trata-se de uma adaptação feita no LVEE monousuário [4], contando com novas interfaces, tecnologias e funcionalidades.

A organização deste trabalho envolve considerações adicionais sobre AVC (seção 2), na seção 3 são apresentadas as características do projeto LVEE, finalmente, na seção 4 são discutidas algumas considerações sobre o desenvolvimento do projeto até o presente momento.

2. Ambientes Virtuais Colaborativos

O uso de ambientes virtuais multiusuário vem crescendo rapidamente, uma vez que permitem que diversos usuários possam interagir num ambiente virtual compartilhado, através de redes de computadores, solucionando o problema de usuários geograficamente dispersos e melhorando o desempenho coletivo através da troca de informações. O uso de ambientes virtuais multiusuário em sistemas cooperativos permite aos participantes interagirem com o mais alto grau de naturalidade, pois através do ambiente é possível comunicação por meio de imagem, vídeo, texto e áudio.

Segundo Sighal [5], um ambiente virtual multiusuário é distinguido pelos cinco fatores apresentados a seguir:

- Um senso de compartilhamento de espaço: todo o participante tem a sensação de estar sendo colocado no mesmo local, mesma sala, prédio ou terreno.
- Um senso de compartilhamento de presença: quando da entrada no ambiente virtual, cada participante deve ter uma identificação clara, normalmente é escolhida uma "identidade virtual", chamada *avatar*, a qual inclui uma representação

[1] Departamento de Engenharia Elétrica - Universidade Federal do Pará (UFPA), C.P. 8619 - CEP 66075-900 Belém - PA – Brasil, grvufpa@grupos.com.br

gráfica, modelo de estrutura corporal, modelo de movimentação, modelo físico, e outras características.

- Senso de compartilhamento de tempo: participantes deveriam estar aptos a ver outros comportamentos, e como eles ocorrem em tempo real.
- Uma maneira de comunicação: embora a visualização forme a base eficaz de uma ambiente virtual multiusuário, a maioria deles deve também permitir a comunicação entre os participantes – por gestos, por texto ou por voz, por exemplo.
- Uma maneira para compartilhar: os elementos acima mencionados fornecem efetivamente um sistema de vídeo conferencia de alta qualidade. Contudo, o verdadeiro poder dos ambientes virtuais multiusuários está na habilidade de uma interação realística não somente com os outros usuários, mas também com o próprio ambiente virtual.

3. Laboratório virtual de Experiências de Eletrônica

A proposta é utilizar a Realidade Virtual como uma *interface* mais natural entre aluno-computador, para simulação de circuitos elétricos usando resistores, capacitores, indutores, fontes e fios. Contudo, o que deve ser ressaltado nesta etapa de desenvolvimento do LVEE e á possibilidade de compartilhamento do ambiente virtual tridimensional em tempo real, onde é feita a experiência com circuitos elétricos. Assim, o professor pode demonstrar ao aluno como ele deve proceder tanto na montagem do circuito, como na simulação do mesmo, e apesar do ambiente ser compartilhado por vários alunos, a impressão é que cada um está tendo a sua aula particular.

3.1 Aspectos Tecnológicos

Para o desenvolvimento deste protótipo, utilizaram-se VRML (Virtual Reality Modeling Language) [6], linguagem utilizada para a modelagem e construção de ambientes virtuais tridimensionais e JAVA [7]. Além disso, há necessidade de uma *interface*, chamada EAI (*External Authoring Interface*) [8], que permita a comunicação entre uma *applet* JAVA e um ambiente VRML. Além destas, foi utilizado também um simulador de circuitos elétricos, chamado SPICE (*Simulation Program with Integrated Circuit Emphasis*) [9]. O protótipo conta com um banco de dados e o SGBD utilizado é o Microsoft Access 2000. A arquitetura do sistema proposto é apresentada na Figura 1.

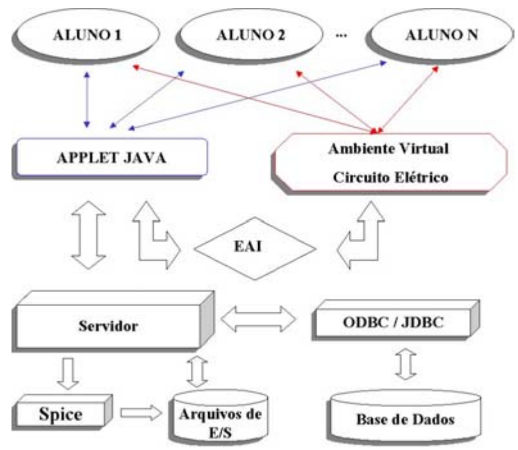

FIGURA 1:
VISÃO GERAL DA ARQUITETURA DO LVEE.

3.2 Modelo de Comunicação

A arquitetura de comunicação utiliza os conceitos do modelo de comunicação Cliente/Servidor (Figura 2). A idéia é simples: de um lado tem-se o sistema do usuário funcionando como o cliente, a qual faz requisições de serviços a uma outra aplicação denominada servidor [10]. A comunicação realizada no sistema ficou restrita à comunicação baseada em sockets (classes Socket e DatagramSocket) e threads, devido ao fato de possuírem interfaces de programação de baixo nível para comunicação em rede, em que o envio de dados entre as aplicações ocorrem através de streams.

O usuário através do *browser Web* envia um pedido de abertura de conexão a um servidor que é executado em determinado *host*. Uma mensagem de confirmação de conexão é enviada, em seguida a *applet* envia dados ao servidor para serem processados. Posteriormente, o servidor responde ao pedido da *applet* enviando os dados do pedido.

A maneira mais comum de implementar um servidor multiusuário é a implementação de servidores com *threads*. No momento que um cliente estabelece conexão com o servidor, uma nova *thread* é criada para atender esse cliente.

A Figura 2 mostra, ainda, o processo de mensagens entre os clientes conectados. Quando um usuário envia uma mensagem ao servidor, a mensagem é tratada pela *thread* associada ao usuário. A *thread* filtra e repassa aos outros clientes conectados. Assim, todos os clientes comunicam-se exclusivamente com a *thread* que os associa ao servidor.

Existem vários tipos de mensagens no LVEE, entre elas as mais importantes são: mensagens de mudança de posicionamento dos objetos, de *chat*, de inserção e remoção de componentes, de simulação do circuito e mensagem de resposta da simulação de circuitos. Cada mensagem é identificada por um campo ID.

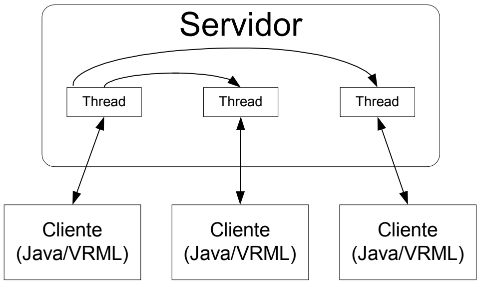

FIGURA 2:
ESTRUTURA DE COMUNICAÇÃO BASEADA EM *THREADS*.

3.3 Arquitetura do Protótipo

A seguir será mostrado o diagrama de classes do protótipo utilizando-se a notação UML [11], por se tratar de uma notação muito utilizada na representação de sistemas computacionais. E o modelo entidade-relacionamento do banco de dados.

3.3.1 Diagrama de Classes

O diagrama de classe UML do sistema é apresentado na Figura 3. A classe *Servidor* instancia a classe *Leitor* (subclasse de *Thread*) para cada usuário que se conecta no sistema.

Assim como a classe *Servidor*, a classe *Cliente* instancia a classe *Leitor* para receber as mensagens vindas do Servidor.

A classe *Gerenciador de BD* é responsável por manter a consistência do banco de dados que reflete o desenvolvimento da aula. Por exemplo, quando ocorre uma inserção de componente na aula, a representação deste componente é persistida no banco de dados.

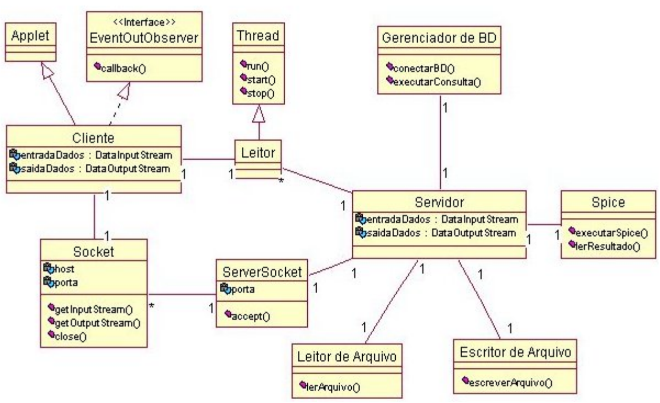

FIGURA 3:
DIAGRAMA DE CLASSES DO SISTEMA.

3.3.2 Modelo Entidade-Relacionamento

O modelo Entidade-Relacionamento gerado pelo Microsoft Access 2000 é apresentado na Figura 4. Como se trata de um modelo colaborativo, foi criado o conceito de grupo para controlar a aula, e os usuários são cadastrados no grupo.

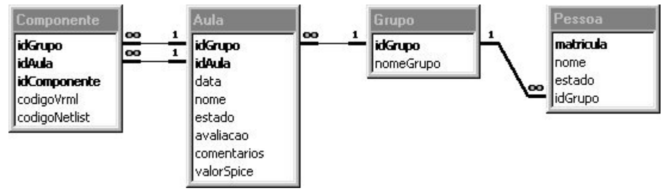

FIGURA 4:
MODELO ENTIDADE-RELACIONAMENTO.

De acordo com o modelo, um grupo pode criar várias aulas, estas, por sua vez, podem estar associadas a vários componentes.

3.3.3 Diagrama de Seqüência

Aqui nesta seção, são fornecidos alguns diagramas de seqüência que proporcionam uma visão abstrata de como se comportam os componentes do protótipo. Dentre as principais mensagens do sistema, estão representadas, aqui, a simulação (Figura 5), a inserção de objetos (Figura 6)e a conexão (Figura 7).

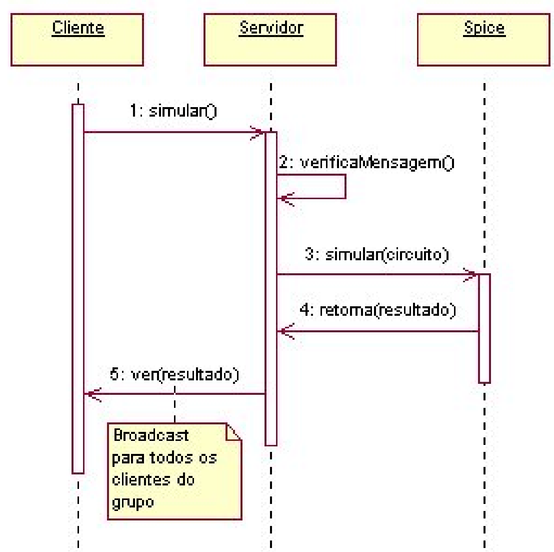

FIGURA 5:
DIAGRAMA DE SEQÜÊNCIA PARA A SIMULAÇÃO

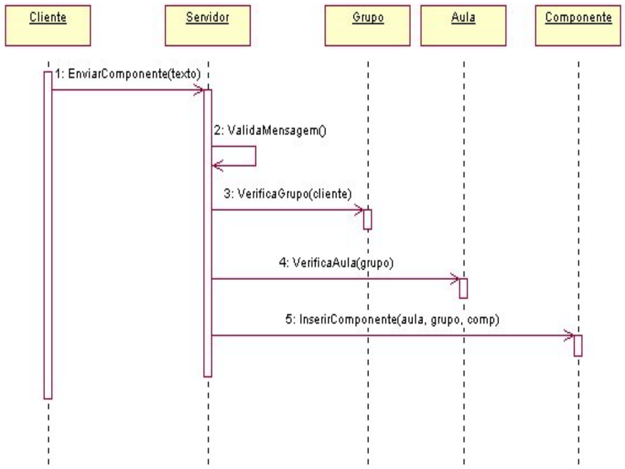

FIGURA 6:
DIAGRAMA DE SEQÜÊNCIA PARA A INSERÇÃO DE OBJETOS

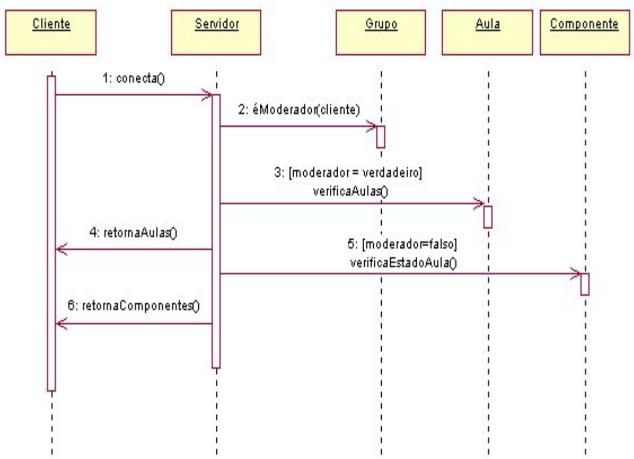

FIGURA 7:
DIAGRAMA DE SEQÜÊNCIA PARA A CONEXÃO DO USUÁRIO

3.4 O Ambiente Virtual

As experiências virtuais são de fácil criação, onde o usuário tem a total liberdade para montar e visualizar o circuito criado. E a simulação dos circuitos elétricos é feita através do PSPICE.

A *interface* do protótipo é composta de duas partes principais (Figura 8): a primeira é destinada à visualização e manipulação dos componentes, e a segunda é a *applet* que se divide em uma parte de chat, onde o usuário se conecta e realiza troca de mensagens com os outros usuários, e outra para a criação e simulação do circuito. Tanto o ambiente virtual quanto a *applet* fazem parte de uma página Web, assim o protótipo pode ser acessado de qualquer computador que tenha acesso a Internet.

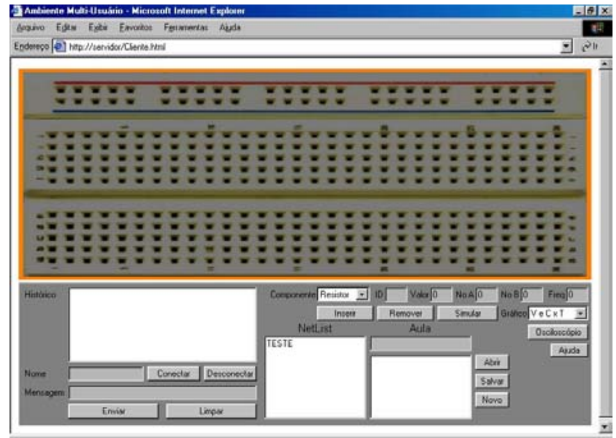

FIGURA 8:
VISUALIZAÇÃO DA PÁGINA DO PROTÓTIPO.

No experimento, ao inserir um componente (um resistor, um capacitor, uma fonte, um indutor ou um fio) seu modelo tridimensional é inserido na cena na posição especificada pelo usuário, seu código para o SPICE é inserido na caixa de texto do `netList` (arquivo que descreve o circuito e serve como parâmetro de entrada para o SPICE), e sua representação é armazenada no banco de dados.

Um exemplo de NetList é vista na figura 9.

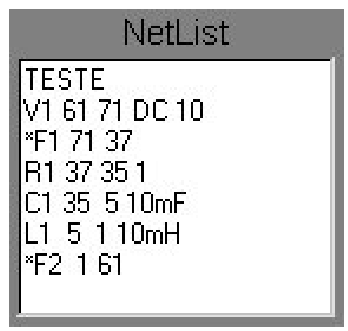

FIGURA 9:
NETLIST APÓS INSERÇÕES DE COMPONENTES.

Após inserir todos os componentes e montar a estrutura do arquivo para o SPICE, simula-se o resultado do experimento, clicando no botão `Simular`. O resultado gerado pelo SPICE é exibido em uma página HTML para análise pelo usuário. Qualquer mudança no circuito é prontamente percebida por todos os outros usuários que estão conectados ao servidor, seja ela de inserção, remoção ou simulação.

Além de simular, o usuário pode verificar o comportamento do circuito através de um gráfico de osciloscópio (Figura 10).

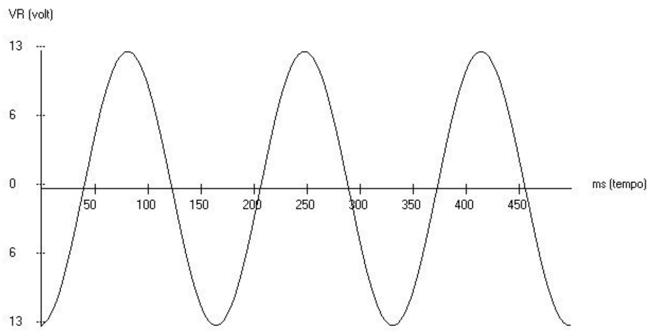

FIGURA 10:
GRÁFICO DO CIRCUITO.

O gráfico da Figura 10 mostra a tensão no resistor variando no tempo.

4. Considerações finais e trabalhos futuros

Neste trabalho foram apresentadas extensões ao LVEE (Laboratório Virtual de Experiências de Eletrônica), de modo a torná-lo multiusuário e colaborativo. Acredita-se que tais extensões de fato tornaram o LVEE ainda mais propício ao emprego como ferramenta auxiliar no ensino de engenharia elétrica.

Como futuros trabalhos, pretende-se desenvolver um simulador de circuitos elétricos escrito em JAVA, de modo a não se necessitar mais do SPICE. Isto tornará o LVEE plenamente portável para as diversas plataformas computacionais existentes, além de facilitar em muito futuras atualizações. Por fim, pretende-se investigar a utilização do LVEE em maior escala, de modo a se avaliar na prática o grau de benefício oriundo de seu uso.

Uso da Linguagem Natural para Manipulação e Interação de Ambientes Tridimensionais Educacionais para Engenharia Elétrica

Bianchi Serique Meiguins[1,2], Breno Serique Meiguins[1], Luiz Affonso Guedes[1], Marcos Paulo Alves de Souza[1], Marcelo de Brito Garcia[1], Gustavo Campos [2], Rosevaldo Dias de Souza Júnior[2].

Abstract: *The aim of this article is to make possible that users can have a better interaction in the manipulation of a three-dimensional environment using the natural language, for that, we propose an integration among VRML (Virtual Reality Modeling Language), JAVA and PROLOG (Programming in Logic). As case study we have used the tool to support the learning of electric circuits, namely LVEE (Virtual Laboratory for Electronic Experiences), that it is a three-dimensional environment for simulation of electronic experience. The LVEE interface allows the construction of circuits using 3D components, as well as simulations local or remote of the created circuits.*

Keywords*: Java, LVEE, Prolog, VRML.*

Resumo: *O objetivo deste artigo é possibilitar que usuários possam ter uma melhor interação na manipulação de uma ambiente tridimensional utilizando a linguagem natural, para isso propõe-se uma integração entre VRML (Virtual Reality Modeling Language), JAVA e PROLOG. Como estudo de caso propõe-se o uso de uma ferramenta de auxílio ao aprendizado de circuitos elétricos, chamado LVEE (Laboratório Virtual de Experiências de Eletrônica), que é um ambiente virtual tridimensional para simulação de experiências de circuitos elétricos. A interface do LVEE permite a construção de circuitos elétricos usando componentes 3D, bem como simulações locais ou remotas dos circuitos criados.*

Palavras-chaves: *Java, LVEE, Prolog, VRML.*

1. Introdução:

Com a evolução constante das tecnologias aplicadas a interfaces do usuário, uma nova geração de interfaces vem se estabelecendo. Dentre as novas tecnologias de interface surge com destaque a Realidade Virtual (RV) facilitando a visualização, manipulação e interação de usuários com ambientes computacionais tridimensionais (3D). Além da RV, a Inteligência Artificial (IA) também vem para melhorar a interação do usuário com o ambiente, e que juntas se torna uma grande e poderosa combinação tecnológica para o desenvolvimento de ambientes tridimensionais inteligentes, que é o próximo passo evolucionário para o desenvolvimento de interface humano-computador [1] [2].

Foi com o objetivo de utilizar as características disponibilizadas pela Realidade Virtual à Educação que o Laboratório Virtual de Experiências de Eletrônica (LVEE) foi concebido [3]. O LVEE é um ambiente virtual que propicia ao aluno criar de forma tridimensional, circuitos elétricos e em seguida simulá-los, obtendo resultados, como por exemplo, de correntes e tensões nos componentes do circuito criado. Contudo, devido à interface do protótipo conter vários campos e botões a serem preenchidos ou acionados, pensou-se em uma forma de melhorar a usabilidade de interação com a interface, tornando-a mais simples e intuitiva. Esta melhora se deu através do uso de um Processador de Linguagem Natural (PLN), que proporciona ao usuário a possibilidade de trabalhar ou interagir com o protótipo através de sua língua natural. As simulações podem ser feitas local ou remotamente, através da Internet, estendendo as possibilidades citadas do uso da Realidade Virtual para Educação a Distância (EAD).

Esta ferramenta, denominada de LVEE com PLN, faz uso das seguintes tecnologias (Figura1):

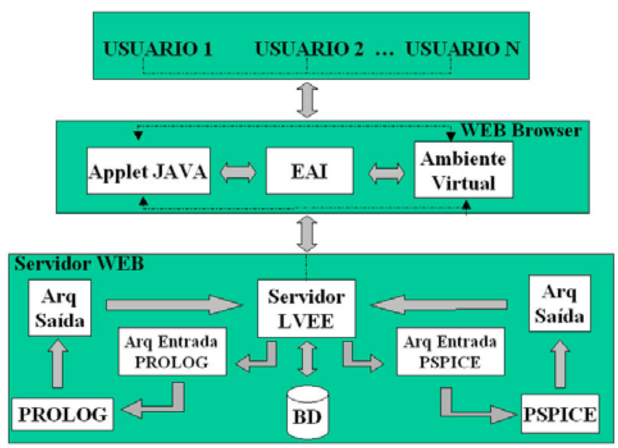

FIGURA 1:
RELACIONAMENTO ENTRE AS PRINCIPAIS TECNOLOGIAS DO PROTÓTIPO.

- **VRML** é um padrão internacional para a descrição de ambientes virtuais através de primitivas tridimensionais

[1] Departamento de Engenharia Elétrica - Universidade Federal do Pará (UFPA), C.P. 8619 - CEP 66075-900 Belém - PA – Brasil, grvufpa@grupos.com.br
[2] Área de Ciências Exatas e Tecnologia - Centro de Ensino Superior do Pará (CESUPA), Avenida Governador José Malcher, 1963 CEP 66060-230 - Belém – PA – Brasil.

como: cubo, esfera, cilindro e outras formas mais complexas utilizando polígonos ou deformações.

- **EAI** (*Extherinal Authoring Interface*) [5] foi projetada para que um programa externo, como *applet* Java, envie mensagens para os objetos existentes no ambiente VRML, realizando ações como a criação de outros objetos ou animações.
- **PROLOG:** responsável pelo processamento lingüístico das sentenças levando em consideração todas as características da língua portuguesa.
- **PSPICE** SPICE é um acrônimo para *Simulation Program with Integrated Circuit Emphasis*. Foi desenvolvido na Universidade da Califórnia em Berkeley, no início dos anos 70 e calcula o comportamento do circuito [4].

2. Laboratório Virtual de Experiências de Eletrônica

A proposta é utilizar a Realidade Virtual como uma interface mais natural entre aluno-computador, para simulação de circuitos elétricos com componentes passivos, ou seja, usando resistores, capacitores, fontes e indutores. Contudo, essas experiências não devem ficar restritas a circuitos elétricos, e ao conjunto dessas experiências deu-se o nome de Laboratório Virtual de Experiências de Eletrônica.

Devido às dificuldades de ensino/aprendizagem, para o curso de Engenharia Elétrica tradicional, é proposta a utilização de sistemas baseado em Realidade Virtual com o objetivo de minimizar os problemas citados ou resolvê-los por completo, sempre deixando claro que a Realidade Virtual deve ser usada como mais uma ferramenta para auxiliar o ensino presencial e não como substituta do mesmo.

A proposta do projeto LVEE tem como objetivos:

- Disponibilizar o conhecimento para aprendizado e revisões complementares das disciplinas envolvidas;
- Possibilitar maior tempo para a prática das experiências, levando em consideração o próprio ritmo do aluno;
- Facilitar o aprendizado, através de uma interface interativa que utiliza os conhecimentos já adquiridos no mundo real;
- Reduzir o custo de implantação de laboratórios, ao menos nas tarefas mais rotineiras e nas fases iniciais de aprendizado;
- Avaliar a potencialidade da RV na educação;
- Possibilitar fácil atualização do conjunto de experiências nos laboratórios virtuais e
- Avaliar a potencialidade e dificuldades na integração do VRML x Java.

3. Arquitetura de Comunicação

Apesar do LVEE ainda ser um ambiente virtual monousuário, ele permite que várias instâncias sejam executadas simultaneamente. Ou seja, há a possibilidade de dois ou mais alunos estarem simulando seus circuitos ao mesmo tempo, sem que um interfira no outro. O modelo cliente-servidor é utilizado, e é implementando através da programação em Java utilizando *threads* e *sockets*, onde cada *thread* gerencia a conexão, e cada conexão é feita por um par de *sockets* que ligam o computador do aluno (cliente) ao o servidor onde está instalado o LVEE (Figura 2).

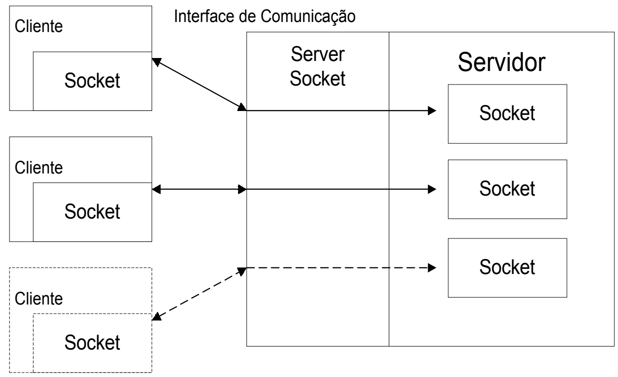

FIGURA 2:
ARQUITETURA DE COMUNICAÇÃO DO LVEE.

4. Protótipo.

O protótipo é carregado em uma página Web que é composto de duas partes. Uma para o AV e outra para a *applet*. O AV consiste de um protoboard onde o usuário poderá visualizar o circuito tridimensional montado. Um exemplo de AV com alguns componentes inseridos pode ser visto na Figura 3.

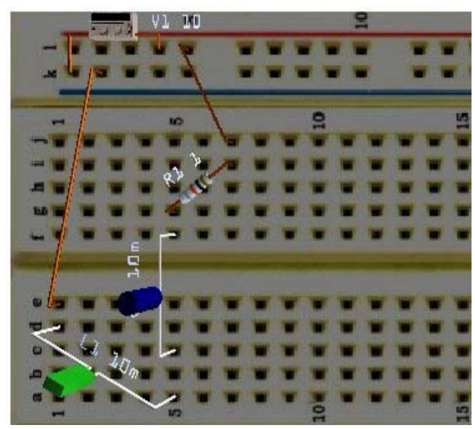

FIGURA 3:
EXEMPLO DE UM EXPERIMENTO INSERIDO NO AV PARA SIMULAÇÃO

É no AV que o usuário perceberá modificações decorrentes de sua interação com a applet. Nela pode-se inserir e remover componentes eletrônicos, como: fonte, fio, resistor, indutor e capacitor, para realizar simulações de circuitos eletrônicos. O usuário poderá “descrever” as ações a serem executadas no LVEE como um todo através do campo **Mensagem** na applet (Figura 5). A *applet* com vários botões possui uma usabilidade de interação para a interface bastante complexa para um usuário comum. Esta interface pode ser vista na Figura 4.

FIGURA 4:
TELA DE INTERAÇÃO ENTRE O USUÁRIO E O SISTEMA

Contudo com o objetivo de melhorar a usabilidade na interação homem-computador, foi desenvolvido um PLN para ser usado na composição da interface, possibilitando assim uma melhora bastante significativa na interface da *applet*, tornando-a mais simples, intuitiva e tão funcional quanto à da Figura 4. A interface da *applet* utilizando as técnicas de PLN pode ser vista na Figura 5.

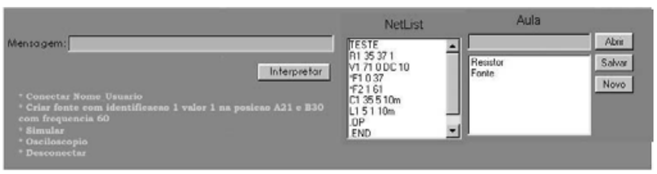

FIGURA 5:
TELA DE INTERAÇÃO ENTRE O USUÁRIO E O SISTEMA ATRAVÉS DE LINGUAGEM NATURAL

A interface da *applet* contém dicas de como utilizar os comandos básicos do protótipo descritos na cor cinza a baixo do campo **Mensagem**. Este campo fornece a principal forma de interação entre o usuário e o protótipo.

Quando o usuário descreve o que quer no campo reservado para esta ação e posteriormente clica no botão **Interpretar** o módulo SERVIDOR é acionado para criar/escrever um arquivo de entrada de parâmetros para em seguida chamar o módulo PROLOG a ser executado, pois ele é responsável pela interpretação da sentença que passa por analisadores léxico, sintático e semântico, na verdade para todas as ações pedidas pelo usuário são criadas mensagens e enviadas ao servidor, e especificamente para o PLN para que possam ser interpretadas. O léxico transforma as unidades significativas das palavras, em identificadores (tokens); o sintático verifica se os tokens estão corretos de acordo com as regras gramaticais pré-definidas; o semântico implica atribuições de significado as estruturas geradas pela análise sintática [5] [6]. Com o término do processo de interpretação o PROLOG gerará um arquivo de saída que servira de entrada para o módulo SERVIDOR que ficou a espera dos parâmetros para retornar uma resposta ao usuário, que pode ser um retorno de erro como na Figura 6 ou resposta correta do pedido do usuário, como inserção de um objeto no ambiente virtual.

FIGURA 6:
RESULTADO GERADO PELO PLN

A primeira tarefa que o usuário deve executar no LVEE é Conectar. Para esta operação o frase usada é "Conectar Nome_Usuário". Após a descrição desta sentença, o usuário clicará no botão **Interpretar** para realizar o *login* do usuário no servidor, para que este possa se beneficiar de todos os serviços disponíveis pelo mesmo. Caso haja aulas específicas salvas pelo aluno da autenticação, seus nomes serão carregados para uma caixa de texto, para posterior seleção e carregamento das mesmas. As aulas estão armazenadas em um Banco de Dados (BD) no servidor.

Após a conexão o usuário poderá iniciar as suas experiências ou reeditar as que estiverem salvas.

Outro exemplo é quando o usuário desejar inserir no protoboard um resistor com valor 2 (dois) nas posições A21 e B30, neste caso, terá que se construir uma frase da seguinte forma: "Criar um resistor com identificação 9 valor 2 no A21 e no B30" ou "Criar R9 valor 2 no A21 e no B30".

Ao término da interpretação tem-se um resultado com alguns parâmetros gerados como mostrada Figura 7.

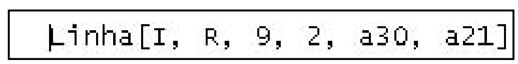

FIGURA 7:
RESULTADO GERADO PELO PLN

Ao término do processo de comunicação do módulo SERVIDOR com o arquivo de saída do PROLOG, o servidor repassará para a Applet JAVA os parâmetros obtidos, que atualizará o ambiente virtual com o componente especificado.

O usuário ainda poderá solicitar através da *applet* que o protótipo disponibilize a simulação dos circuitos elétricos construídos, e em seguida os gráficos de um osciloscópio.

Quando o usuário descreve na applet a ação de simular experimento, o SERVIDOR aciona o módulo SPICE, que por sua vez fará toda a simulação do experimento através de cálculos matemáticos retornando um resultado que será repassado ao usuário em uma nova página em formato HTML para sua análise. Um resultado de simulação pode ser visto na Figura 8 logo abaixo.

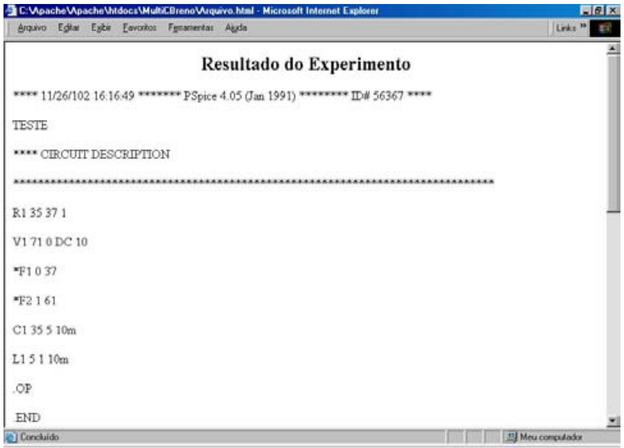

FIGURA 8:
RESULTADO DA SIMULAÇÃO DA EXPERIÊNCIA.

Após a simulação, se tudo estiver de acordo, ou seja, o experimento estiver de acordo com as regras pré-definidas para o funcionamento do circuito o usuário ainda poderá solicitar através da *applet* a geração dos gráficos de um osciloscópio. Utilizando o campo **Mensagem** com "gráfico osciloscópio", um dos resultados pode ser visto na Figura 9.

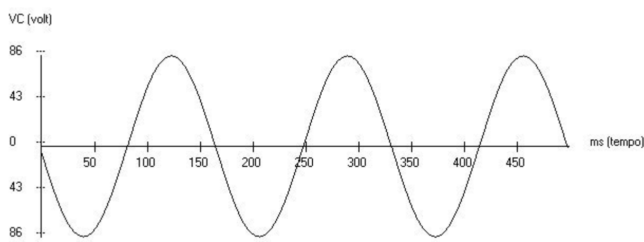

FIGURA 9:
RESULTADO DA GERAÇÃO DE UM GRÁFICO OSCILOSCÓPIO

O campo descrito como Netlist é o campo reservado para mostrar ao usuário qual o resultado obtido depois da interpretação do PLN em forma de códigos parametrizados de acordo com a experiência dos circuitos elétricos inseridos no ambiente. Um exemplo do Netlist com componentes pode ser visto na Figura 10.

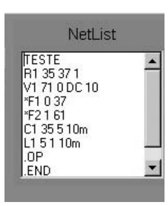

FIGURA 10:
CAMPO NETLIST COM OS PARÂMETROS

Os campos a baixo do texto onde está descrito **Aula** têm por finalidade realizar as seguintes ações: a segunda caixa de texto localizada a baixo da palavra **Aula** é utilizada para disponibilizar para o usuário as aulas salvas pelo mesmo, caso o usuário queira abrir uma aula salva anteriormente basta o mesmo clicar em cima da aula desejada e clicar em cima do botão **Abrir**, podendo assim continuar a execução ou o estudo de uma aula interrompida por algum motivo anteriormente. O botão **Salvar** é utilizado para salvar a experiência atual no ambiente sendo que para isto é necessário adicionar algum nome significativo para esta aula na primeira caixa de texto ao lado do botão "Novo". Por fim, o botão **Novo** é utilizado para disponibilizar um novo ambiente com o protoboard totalmente vazio apto para novas simulações de experiências. Um exemplo de algumas aulas salvas mostradas na caixa de texto pode ser visto na Figura 11.

FIGURA 11:
VISUALIZAÇÃO DO CAMPO AULA

Além de o usuário ter todas estas possibilidades descritas acima, o mesmo ainda poderá usar a opção de ajuda descrevendo no campo Mensagem "ajuda". Serão fornecidos exemplos e explicações de como agir para que o funcionamento do protótipo ocorra de acordo com as suas necessidades, esse conteúdo será mostrado em uma página HTML (Figura 12). Por fim, quando o usuário terminar a utilização do protótipo o mesmo terá de solicitar a desconexão com o módulo SERVIDOR através da mensagem "Desconectar".

FIGURA 12:
TELA DE AJUDA

5. Considerações finais

O processamento de linguagem natural usado para melhorar a usabilidade na interação homem-computador em sistemas que possuem AV parece ser bastante promissor, uma vez que, a interação pode ser bastante difícil para determinados usuários que não possuam muita afinidade com o domínio da aplicação, e a informática num segundo momento, facilitando assim a utilização do LVEE. Contudo, vale ressaltar que o PLN foi desenvolvido em PROLOG com o auxílio da gramática de cláusulas definidas e está sujeito a ambigüidades de sintaxe que são ocasionadas pelos limites da mesma.

Além disso, o uso do LVEE poderia ser empregado de forma multiusuário, que é o próximo passo a ser seguido. Contudo, foi necessária primeira a consolidação do ambiente monousuário.

Também, há necessidade de aumentar o domínio da gramática, o que permitiria que o LVEE, por exemplo, pudesse realizar movimentos de visões, tais como: rotacionar e transladar o experimento.

Realidade Virtual Aplicada ao Ensino e Aprendizagem da Cinemática

Bianchi Serique Meiguins[1,2], Breno Serique Meiguins[1], Luiz Affonso Guedes[1], Marcos Paulo Alves de Sousa[1], Marcelo de Brito Garcia[1], Rosevaldo Dias de Souza Júnior[2].

Abstract. The aim of this article is to present a tool for the simulation of three-dimensional objects, which gives support for the students to learning in physics course, in the kinematics area. This tool, namely SEVC (Simulator of Virtual Experiences in Kinematics), it makes possible the student to simulate situations of the objects in movements with speeds, accelerations and varied initial positions.
Keywords: Kinematics, Java, Virtual Reality in Education, VRML

Resumo. O objetivo deste artigo é apresentar uma ferramenta de simulação de objetos tridimensionais, voltada a auxiliar a aprendizagem de alunos no curso de física, na área de cinemática. Essa ferramenta, chamada de SEVC (Simulador de Experiências Virtuais de Cinemática), possibilita ao aluno simular situações objetos em movimentos com velocidades, acelerações e posições iniciais variadas.

Palavras-chave: Cinemática, Java, Realidade Virtual na Educação, VRML.

1. Introdução

O uso da informática como ferramenta de ensino nas escolas de 1º e 2º graus tornou-se importante nos últimos anos no processo de aprendizagem dos alunos, e o resultado disso é a existência de milhares de softwares voltados para educação, muitos deles com características tecnologicamente avançados como som, animação, cores e uma grande variedade de recursos disponíveis no mercado. Atualmente pode-se classificar certas modalidades de produtos de software educacional, tais como: produtos de exercício e prática, com as perguntas e respostas que se esta habituado a encontrar, há os tutoriais que funcionam como uma espécie de guia, programas de simulação e modelagem, os hipertextos e hipermídias, e os jogos educacionais. Além disso, há, ainda, as grandes bases de conhecimento, os chamados sistemas especialistas, neste caso, encontra-se sistemas dirigidos à área de treinamento e atendimento de necessidades eventuais e os tutores inteligentes produzidos para fins educacionais. Na verdade, esta classificação nos é interessante apenas para uma exposição didática.

Na prática, nenhumas destas modalidades de produtos de software educacionais funcionam isoladamente. Atualmente, os sistemas procuram ser híbridos e o que se busca cada vez mais é navegar por todos eles o tanto quanto possível.

Em particular, na modalidade de simuladores, a Realidade Virtual (RV) pode ser uma ferramenta bastante útil na área de educação. Principalmente, pelo fato da RV disponibilizar uma variedade de maneiras à interação humano-computador, utilizando uma combinação de tecnologias cujas interfaces com o aluno podem estimular seus sentidos, novas percepções e uma nova maneira de aprendizagem através da interação com mundos virtuais.

Este artigo tem como objetivo apresentar uma ferramenta de simulação baseada nos conceitos de RV voltada a auxiliar o ensino e a aprendizagem de alunos no curso de física, na área de cinemática [11], como tecnologias de apoio têm-se VRML *(Virtual Reality Modeling Language)*, linguagem Java, e EAI *(External Authoring Interface)*. Essa ferramenta chama-se SEVC (Simulador de Experiências Virtuais de Cinemática), possibilitando o aluno simular situações de movimento de objetos com velocidade, aceleração e posições iniciais variadas, apresentando simultaneamente a simulação vos gráficos relacionados ao movimento escolhido.

De maneira geral, neste trabalho, serão comentadas o uso da RV em Educação e ferramentas que possibilitem o desenvolvimento de protótipos com os benefícios da RV, bem como a apresentação do protótipo construído.Na seção 2 são discutidos usos de RV na educação. Na seção 3 é apresentado o protótipo SEVC, incluindo a motivação, suporte tecnológico e funcionamento. E por fim, na seção 4, são apresentados as considerações finais e trabalhos futuros.

2. Realidade Virtual

A RV pode ser definida como avançadas técnicas de interface, permitindo ao usuário realizar imersão, navegação e interação em tempo real num ambiente sintético tridimensional gerado por computador [1] [3]. Uma das grandes vantagens das tecnologias de RV é possibilitar que todo o conhecimento intuitivo do usuário possa ser deslocado a um outro contexto de manipulação do ambiente virtual.

Os ambientes virtuais estão classificados em ambiente imersivos e não-imersivos. A idéia de imersão está ligada com o sentimento de se estar dentro do ambiente.

[1] Departamento de Engenharia Elétrica - Universidade Federal do Pará (UFPA), C.P. 8619 - CEP 66075-900 Belém - PA – Brasil, grvufpa@grupos.com.br
[2] Área de Ciências Exatas e Tecnologia - Centro de Ensino Superior do Pará (CESUPA), Avenida Governador José Malcher, 1963 CEP 66060-230 - Belém – PA – Brasil.

Geralmente, um sistema imersivo é obtido com o uso de periféricos não-convencionais, tais como capacete de visualização, luvas especiais de manipulação, ou até mesmo o uso de sala de projeções. O valor ainda bastante elevado da aquisição desses dispositivos especiais acaba por restringir o seu uso, principalmente para usuários comuns. Entretanto, como alternativa, tem-se a realidade não-imersiva, baseada em periféricos convencionais, tais como: teclado, *mouse* e monitor, muito mais acessível em termos de custo para os usuários. A evolução dos PCs e do aperfeiçoamento das interfaces dos atuais softwares de RV, possibilitando um maior grau de imersão em ambientes tridimensionais, mesmo para ambientes considerados não-imersivos.

3. A Realidade Virtual na Educação

A criação de mundos virtuais, onde o participante pode se movimentar, ver e manipular objetos, como no mundo físico, poderá constituir um importante recurso no ensino, uma vez que, os alunos poderão descobrir, de uma forma ativa e perspicaz, os conhecimentos anteriormente transmitidos unicamente pelo professor.

Permitindo a experimentação de novos e diferentes ambientes, similar ou não ao mundo real, cujas características e regras serão delineadas de acordo com os objetivos pretendidos para o processo de aprendizagem, assim, os mundos virtuais poderão vir a constituírem locais de pesquisa e investigação que permitam aos professores não só a transmissão pura e simples de conhecimentos, mas a disponibilização de uma ampla e variada informação que permitirá aos alunos, através da experimentação, análise, investigação e crítica, serem os agentes principais da construção de seus conhecimentos, tarefa que deve ser realizada com a cooperação do professor, que assume agora um novo papel, o de facilitador da construção do conhecimento [7] [12].

A interatividade e a manipulação desempenham também, na experiência virtual, um papel educativo importante, permitindo o "aprender fazendo" que se poderá agora generalizar para "aprender manipulando". Se as experiências científicas, exigindo manipulação, não são, em geral, realizadas por falta de meios ou devido a perigos que delas possam ocasionar, no mundo virtual esses problemas inexistem, sendo possível a criação, sem riscos, de qualquer experiência, pela qual os alunos, manipulando os objetos que antes apenas ouviram falar ou viram em fotografia ou vídeo, alcançam novos conhecimentos sobre os mesmos. [6]

Segundo a Doutora Verônica Pantelides da East Carolina University [6] há diversas razões para usar a Realidade Virtual na educação, entre elas destacam-se:

- Maior motivação do estudante;
- O poder de ilustração da Realidade Virtual para alguns processos e objetos é muito maior do que outras mídias;
- Permite uma análise de muito perto ou de muito longe;
- Dá oportunidades para experiências;
- Permite que o aprendiz desenvolva o trabalho no seu próprio ritmo;
- Não restringe o prosseguimento de experiências ao período da aula regular;
- Permite a que haja interação, e desta forma estimula a participação ativa do estudante.

4. O Protótipo SEVC (Simulador de Experiências Virtuais de Cinemática)

4.1 Motivação

O protótipo é uma ferramenta de simulação tridimensional para o estudo da cinemática, mas especificamente para movimento retilíneo uniforme e movimento retilíneo uniformemente variado.

Uma das razões para a concepção do SEVC é a possibilidade de visualizar resultados práticos de teorias das leis da física que antes se restringiam somente a anotações no quadro. Estimulando o aluno a explorar novas situações e novos resultados através de simples manipulações dos objetos virtuais presentes no ambiente simulado.

O SEVC é uma ferramenta que complementa, através de visualizações práticas, a teoria estudada e analisada pelo professor em sala de aula, tornando o conteúdo mais atrativo para o aprendizado.

A proposta deste protótipo tem como objetivos:

- Disponibilizar o conhecimento para aprendizado e revisões complementares das disciplinas envolvidas;
- Possibilitar maior tempo para a prática das experiências, levando em consideração o próprio ritmo do aluno;
- Facilitar o aprendizado, através de uma interface interativa que utiliza os conhecimentos já adquiridos no mundo real;
- Avaliar a potencialidade da RV na educação;
- Possibilitar fácil atualização do conjunto de experiências.

4.2 Suporte Tecnológico

4.2.1 VRML, EAI e JAVA

VRML é uma linguagem de programação que permite a construções de objetos e cenários tridimensionais, e tem vasta aplicabilidade, incluindo entretenimento, interfaces 3D para usuários que usam recursos remotos da Web, ambientes 3D colaborativos, simulações de interatividade para educação, etc.

JAVA é uma linguagem orientada a objetos que possui uma API robusta voltada para construção de aplicações em rede e o desenvolvimento de interface próprio para Internet com o uso de applet [2].

EAI (*External Authoring Interface*) [4] foi projetada para permitir que um programa externo, como *applet* Java, acesse *nodes* (geralmente objetos) em um cenário VRML, usando o modelo de eventos existente no VRML. Neste modelo, um evento de saída de um dado *node* pode ser roteado para um evento de entrada de um outro *node*. Quando o evento de saída gera um evento, o evento de entrada é notificado e seu *node* processa aquele evento.

Scripts são executados dentro de um *browser* VRML. Apesar de usar recursos de rede, não há maneira de um *script* interagir com um código externo Java, tal como um *applet* Java. Por outro lado, a única maneira de usar EAI é como parte de um *applet* Java, como pode ser visto na Figura 1 [5].

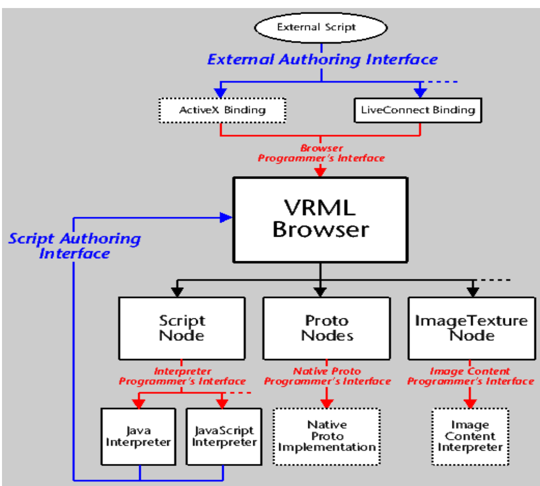

FIGURA 1:
A COMUNICAÇÃO ENTRE AS TECNOLOGIAS VRML, JAVA E EAI [9]

4.3 Funcionamento do SEVC

O protótipo é apresentado em uma página Web que contém uma ambiente virtual tridimensional e uma applet, utilizada para configurar o ambiente virtual e seus objetos. O protótipo carrega um ambiente inicial, simulando uma cidade, o aspecto principal é uma rua com marcações de distância, onde o aluno poderá realizar experiências utilizando um ou dois veículos (Figura 2 e Figura 3).

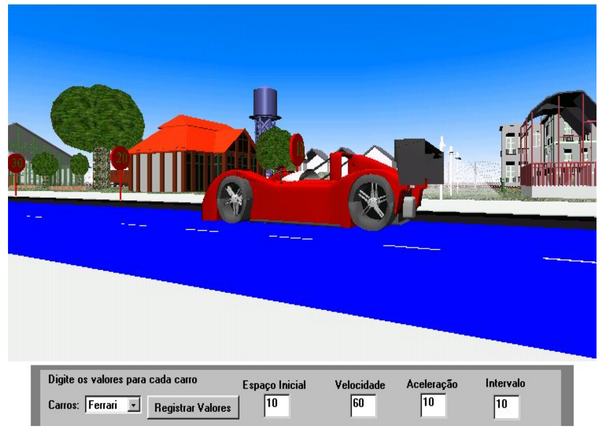

FIGURA 2:
ALUNO INTERAGINDO COM APENAS UM CARRO

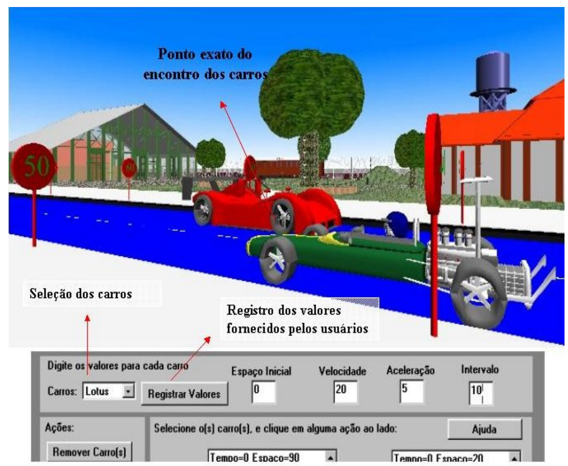

FIGURA 3:
ALUNO INTERAGINDO COM DOIS CARROS EM DIREÇÕES OPOSTAS

O aluno pode interagir com o protótipo através de uma applet, nesta o aluno pode escolher o tipo de carro, entre uma Lotus e uma Ferrari, escolher seu espaço inicial, velocidade inicial e aceleração (Figura 3).

Na parte inferior da applet o aluno pode avaliar o deslocamento do veículo segundo a segundo, e ao final, se a simulação for feita com dois carros terá o tempo e a posição de encontro entre os dois veículos (Figura 4).

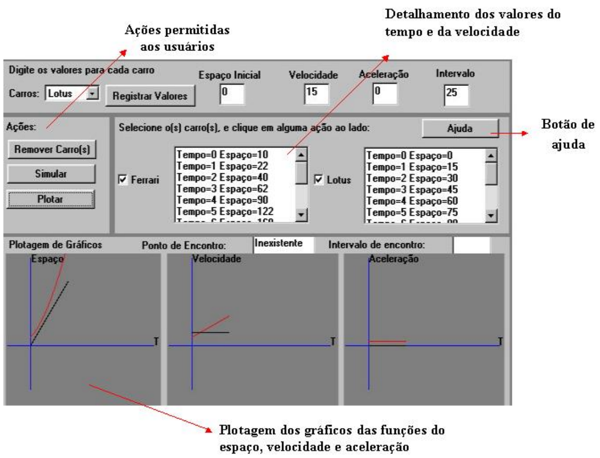

FIGURA 4:
APPLET DE INTERAÇÃO DOS VEÍCULOS

Para determinar o calculo do espaço percorrido é usada a seguinte fórmula da física, $S = So + Vo * T + (A * T^2)/2$, onde: **S**, é o espaço final a ser determinado, **So** é o espaço inicial onde o veículo vai estar, **Vo** é a velocidade inicial do veículo, **A** é a aceleração e **T** é o tempo para a simulação.

Após a configuração dos parâmetros e simular o movimento dos veículos, através do botão simular, ficará disponível a opção *plotar* gráficos, entre eles: espaço x tempo, velocidade x tempo e aceleração x tempo.

O ambiente pode ser observado de diversos ângulos, atividade que poderia ser impossível de realizar dentro de uma sala de aula comum, na RV ela se torna trivial, isso torna o aprendizado mais enriquecedor (Figura 5).

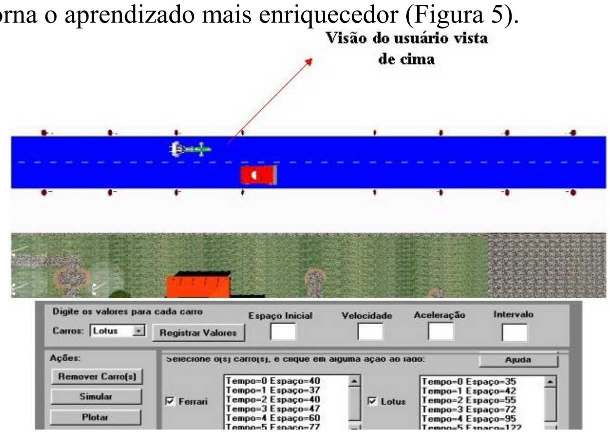

FIGURA 5
MÚLTIPLAS VISÕES DO AMBIENTE

E toda dúvida do aluno em relação às funcionalidades do simulador, ou das próprias teorias da física, especificamente na cinemática, poderá ser solucionada com o auxílio por um tutorial presente no sistema. Nele, há trechos relacionados a conceitos do estudo dos movimentos dos corpos, movimentos com velocidade escalar variável e movimento uniformemente variado. Todo tutorial está estruturado em hipertextos, contendo exemplos de vídeos demostrando as funcionalidades do simulador direcionado as dúvidas do aluno.

5. Considerações Finais e Trabalhos Futuros

As razões para utilizar ambientes virtuais no meio educacional são várias: facilita a motivação, a criatividade, experiências em primeira pessoa, ensino-aprendizagem pela descoberta, controle do tempo e do espaço, desenvolvimento de capacidades e superação de dificuldades, entre outras [6, 8]

A utilização da RV em contexto educativo pressupõe uma concepção de ensino diferente da tradicional, colocando a disposição de educadores e alunos uma nova ferramenta para esta prática de ensino, que tem como principal agente da construção do conhecimento o próprio aluno.

É importante frisar que não é pretensão desta ferramenta a eliminação das tradicionais formas de ensino-aprendizagem, tais como leituras em livros, interação professor-aluno e aluno-aluno. Pretende-se elaborar uma ferramenta que seja aliada ao processo, que possa se tornar parte integrante do mesmo.

Como trabalhos futuros, pretende-se:

- Ampliação dos domínios de aplicação desta ferramenta, não se restringindo somente a cinemática, mas também a outras disciplinas da Física;
- Melhoramentos no ambiente virtual conforme *feedback* dos alunos em relação ao seu uso, interface, funcionalidade, etc.
- Buscar maior grau de imersão do sistema, através da adaptação do simulador ao uso de alguns periféricos, ditos não-convencionais, tais como luvas e óculos 3D.
- Tornar o SEVC um ambiente colaborativo, permitindo a troca de conhecimento entre aluno-aluno ou professor-aluno via *Internet*, em um ambiente tridimensional compartilhado.

UM NOVO SISTEMA DE CONTROLE DE ACESSO PARA LABORATÓRIOS INTERDISCIPLINARES

João Marcos Salvi Sakamoto[1], Alexandre César Rodrigues da Silva [2] e Luis Carlos Origa de Oliveira[3]

Resumo *— A implantação de laboratórios abertos para o ensino interdisciplinar nas áreas tecnológicas tem sido muito discutida. Muitas instituições estão adotando esta sistemática como forma de motivação dos alunos no desenvolvimento de projetos multidisciplinares. Estes laboratórios estariam à disposição dos alunos diuturnamente para que possa haver uma melhor utilização dos recursos disponíveis e maior flexibilidade de horários. No entanto, devido à limitação de funcionários, muitos estão funcionando nos moldes tradicionais. Apresenta-se neste trabalho um sistema para controle de acesso utilizando iButton, para permitir que alunos possam circular livremente em qualquer horário sem a supervisão de funcionários. Este sistema possui vantagens em relação aos outros sistemas, ditos convencionais, como, por exemplo, cartões magnéticos, códigos de barras, etc, pois os iButtons são baratos, podem armazenar uma grande variedade de informações que, quando necessário, podem ser alteradas rapidamente, além do que a comunicação com o sistema hospedeiro é feita através de um simples contato.*

Palavras chave — iButton, controle eletrônico de acesso, projetos multidisciplinares, laboratórios interdisciplinares.

INTRODUÇÃO

Muitos dos componentes sensores de sistemas de controle estão familiarizados no idioma digital universal de 0s e 1s. Recentemente os *iButtons*, com mais de 27 milhões em circulação [15], têm tido emprego em muitos segmentos produtivos do mundo todo como uma extensão dos computadores. Este fato, sem precedentes, fez com que alguns hábitos culturais e econômicos fossem mudados. Os *iButtons* estão sendo usados intensamente como elemento para identificação e ou autenticação, como sensores de temperatura, selo de dados, guarda de propriedade e muitos outros. Alguns casos interessantes de empresas que estão utilizando esta tecnologia de ponta são narrados na literatura [1]. Uma dessas histórias refere-se a uma escola na Flórida que acreditava estar promovendo educação com uma alta dose de tecnologia a seus alunos. Neste espírito, a administração adotou a tecnologia de cartão inteligente como um modo para agilizar rotinas diárias, como destrancar salas de aula, controlar acesso aos computadores, compras na lanchonete escolar ou qualquer outra transação que necessitasse armazenamento de informações. No final de um determinado período o sistema implementado foi desativado pois os frágeis cartões não sobreviviam às manipulações dos estudantes.

Com o advento dos *iButtons*, a escola começou a empregá-los como chaves personalizadas. Dessa forma, qualquer estudante poderia ser facilmente identificado podendo entrar em edifícios, salas de aula, computadores e páginas da Web. Com o formato de um anel metálico, foi emitido para cada estudante um *iButton* contendo as identificações necessárias e que poderia ser usado de acordo com a preferência do indivíduo, ou seja, como um anel de dedo, um relógio de pulso ou um adorno qualquer. Receptores (*Blue Dot*) conectados a computadores permitiram que os estudantes, pelo simples gesto de apertar o botão neste receptor, entrassem na sala de aula, ou registrassem os livros retirados na biblioteca, ou até registrassem os gastos na lanchonete. Um sistema automatizado com essa tecnologia permite que uma escola mantenha um ambiente físico aberto e seguro para cada estudante, que possui acesso a um determinado ambiente, sendo identificado por um símbolo visível e pessoal.

Os *iButtons* vêm sendo empregados em muitas outras atividades como em hospitais, para identificação de pacientes; no registro de temperaturas; em fazendas, para controle da lida com as criações; em equipamentos de alta tecnologia, como um selo de garantia; enfim, o limite para o emprego dos *iButtons* é a criatividade.

Em uma instituição de ensino, como uma universidade, muitas vezes é necessário utilizar laboratórios, computadores ou equipamentos fora do horário normal de funcionamento, a fim de se realizar trabalhos e pesquisas. Como nesses horários não há funcionários para supervisionar o trabalho, é necessário utilizar um meio de supervisão automática ou eletrônica.

Para esse fim, uma solução imediata seria fornecer chaves convencionais aos alunos, porém pode não haver um controle de cópias de chaves.

Pensando nisso, desenvolveu-se, neste trabalho, um sistema de chave eletrônica controlado por um computador, no qual a chave é um *iButton*. Com este sistema, pode-se permitir ou não que alunos tenham acesso a certas áreas da

universidade, visando melhorar o controle de entrada dos prédios e laboratórios.

O QUE É E COMO FUNCIONA UM *IBUTTON*

O *iButton* é uma pastilha (*chip*) de silício armazenada em uma cápsula de aço inoxidável com um diâmetro menor que uma moeda. Seu encapsulamento serve tanto para proteger o *chip* como para prover contato elétrico com o sistema de comunicação. O *iButton* é altamente resistente, podendo sofrer quedas, arranhões e até molhar. Devido a isso, pode ser utilizado diariamente como um acessório digital, em um chaveiro, crachá, anel, entre outros. A Figura 1, extraída de [15], mostra um *iButton* e seu encapsulamento.

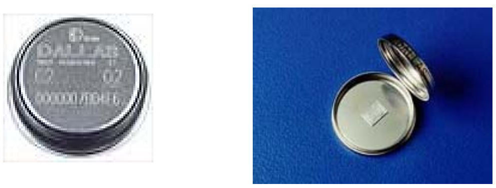

FIGURA. 1
IBUTTON E CÁPSULA ABERTA.

A referência [11] enumera várias especificações técnicas, algumas das quais, citadas a seguir. A cápsula do *iButton* tem 16mm de diâmetro, podendo ter 3.1mm ou 5.9mm de espessura, designados por F3 e F5, respectivamente. A versão F5 é padrão para todos os dispositivos que contém uma fonte de energia interna. Os dispositivos que são energizados pelo mestre podem estar disponíveis também na versão F3. A espessura do aço é de 0.254mm. O material isolante entre a parte inferior e o contato superior é de polipropileno preto, que inibe raios ultra violeta. Este desenho proporciona uma excelente estabilidade mecânica e é resistente à corrosão. Todas as cápsulas resistem a choques mecânicos de 500g (1g = $9.81 m/s^2$) em todas as direções. Uma queda de 1.5m de altura em uma superfície de concreto não danifica o encapsulamento nem seu conteúdo. A Figura 2, extraída de [14], mostra as especificações físicas do *iButton*.

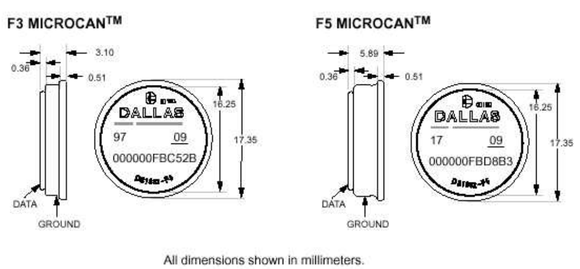

FIGURA. 2
ESPECIFICAÇÕES DOS *IBUTTONS*

No encapsulamento dos *iButtons* há várias informações gravadas, como o número de série, o tipo de *iButton*, etc. A Figura 3, extraída de [11], mostra o significado das informações gravadas.

A comunicação dos *iButtons* com o sistema hospedeiro é realizada serialmente através do protocolo 1-Wire [2], onde é necessário apenas um fio de dados e um retorno (terra). O próprio encapsulamento fornece os contatos para a comunicação, onde o topo é o contato de dados e a base é o terra.

Há diferentes tipos de *iButtons* disponíveis, sendo que cada tipo possui funções específicas, como termômetro, calendário com relógio, memória reprogramável, etc. Todos os *iButtons* possuem um número de série único gravado em uma memória de 64 bits, sendo que os 8 primeiros bits são o código que identifica a família do *iButton*, os próximos 48 bits são o número de série único, e nos últimos 8 bits é implementado um algoritmo de checagem dos 56 bits anteriores. Além das características citadas anteriormente, todos possuem as seguintes características comuns [14]:

- Identificação digital e informações através de contato momentâneo;
- Armazenamento informações de maneira compacta;
- Os dados podem ser acessados enquanto estiverem fixados em algum objeto;
- Comunicam-se com o barramento com um simples sinal digital a 16.3 kbits por segundo;
- Tamanho padrão e protocolo padrão asseguram compatibilidade com a família *iButton*;
- A superfície do *iButton* se encaixa na superfície do hospedeiro;
- Encapsulamento de aço inoxidável resistente a ambientes severos;
- Podem ser fixados facilmente com adesivos ou anéis de fixação;
- Detector de presença que reconhece quando o leitor aplica uma tensão.

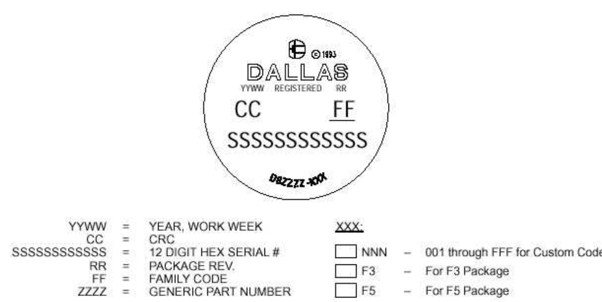

FIGURA. 3
INFORMAÇÕES GRAVADAS NOS *IBUTTONS*

O *iButton* não necessita de fonte de alimentação, pois ele retira energia da própria linha de dados no momento do contato.

Pode-se operar com vários *iButtons* simultaneamente através de uma rede para comunicação digital. Há diversos meios de comunicação, como o *Blue Dot* (serial ou paralelo), caneta para leitura, adaptador serial ou paralelo, apresentados na Figura 4, respectivamente, extraída de [15].

FIGURA. 4
BLUE DOT, CANETA DE LEITURA E ADAPTADOR SERIAL

O *iButton* possui vários acessórios de fixação e de uso pessoal. Os acessórios de fixação são usados para colar o *iButton* na superfície de um objeto qualquer, através de adesivos ou anéis de fixação, ou soldar em uma placa de circuito impresso. Entre os acessórios de uso pessoal, estão chaveiros, carteiras, anéis, pulseiras de relógio, entre outros.

IBUTTON PARA CONTROLE DE ACESSO

O *iButton* para controle de acesso mais simples é designado pelo número DS1990A e possui o número de série como característica principal. No entanto, pode-se usar qualquer tipo de *iButton* para controle de acesso, pois todos possuem um número de série. O DS1990A consiste em uma memória ROM de 64 bits e possui também as seguintes características [14]:

- Vários DS1990A podem coexistir em um mesmo barramento;
- Chave eletrônica de baixo custo;
- Pode ser lido em menos de 5 ms;
- Temperatura de operação de -40^{o}C a $+85^{o}$C;

UM NOVO SISTEMA DE CONTROLE DE ACESSO PARA LABORATÓRIOS

A proposta do sistema foi substituir a chave convencional e trabalhar de modo semelhante aos cartões magnéticos ou códigos de barras, ou seja, deve haver um leitor na porta e um computador para controlar a entrada do usuário. Assim, desenvolveu-se um novo sistema de controle de acesso utilizando *iButtons* como chaves, um *Blue Dot* como leitor e um computador para verificação da permissão de entrada dos usuários e auditoria.

Desenvolveu-se, então, um programa em Linguagem C para controlar o sistema, ou seja, ler o *iButton*, verificar se este está autorizado e, em caso afirmativo, abrir a porta através de uma trava eletrônica.

Utilizou-se um ambiente denominado *TMEX* [12] para utilizar rotinas de comunicação com o *iButton*. O ambiente *TMEX* é um conjunto de drivers e programas utilitários que permitem a comunicação dos *iButtons* e acessórios utilizando um microcomputador.

A ferramenta utilizada para desenvolver o programa foi o *Professional Software Developer's Kit* (DS0621-SDK) [10], que contém os códigos fonte de todos os aplicativos *TMEX* e os arquivos necessários para que as funções *TMEX* sejam compiladas. Para utilizar o software desenvolvido é necessário que o *TMEX* esteja instalado e configurado no microcomputador.

A partir do estudo das funções *TMEX* e de alguns aplicativos prontos, pode-se desenvolver o programa de controle de acesso. O sistema operacional escolhido foi o *MS-DOS* devido ao fato de ser um sistema simples e qualquer microcomputador padrão *IBM-PC* pode executá-lo facilmente. Isso é uma vantagem, pois pode-se utilizar computadores ultrapassados e ociosos sem custo adicional.

O programa executa os seguintes passos: inicializa os drivers e testa se as configurações estão corretas. Em seguida, fica em espera e quando um *iButton* toca o *Blue Dot*, lê o seu número de série e compara com os números de série autorizados em um arquivo. Se o *iButton* não estiver autorizado, o programa emite um ruído, registra no arquivo de auditoria que um *iButton* não autorizado tentou acessar o sistema e volta ao estado de espera. Se o *iButton* for autorizado, o programa registra no arquivo de auditoria o nome do usuário, a data e o horário de acesso e, em seguida, abre a trava eletrônica.

Após vários testes obteve-se êxito com o programa, que funcionou corretamente. Com isso, testou-se o sistema como um todo, ou seja, implementou-se o sistema com o microcomputador, *Blue Dot*, adaptador serial, transformador (220-12V), circuito de potência e trava de porta eletrônica, como mostra a Figura 5 e, em detalhes, a Figura 6.

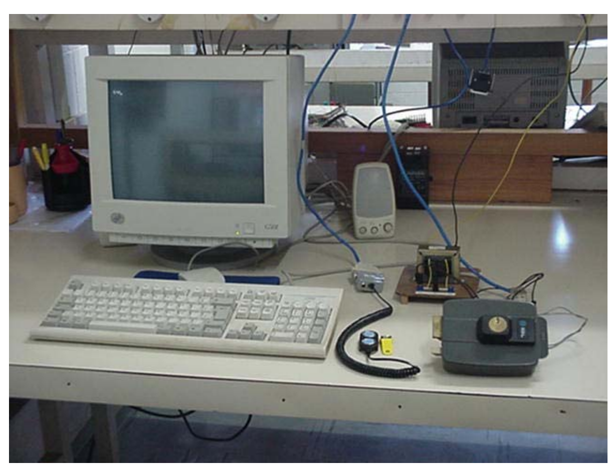

FIGURA. 5
SISTEMA DE CHAVE ELETRÔNICA.

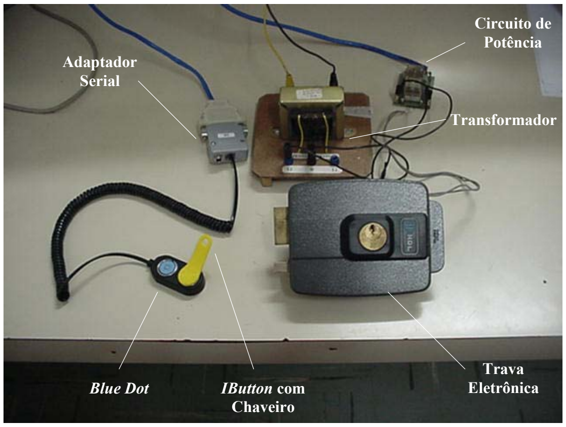

FIGURA. 6
SISTEMA EM DETALHES.

O teste foi realizado no Laboratório de Processamento de Sinais e Sistemas Digitais da Faculdade de Engenharia de Ilha Solteira e obteve-se sucesso, ou seja, os *iButtons* cadastrados abriram a trava e os não cadastrados não abriram. Deve-se salientar que se utilizou *iButtons* de vários tipos, pois todos possuem um número de série único.

Uma parte importante do projeto é a auditoria, que neste primeiro momento foi realizada gravando o nome do usuário, a data e o horário de entrada. Porém, de acordo com certas necessidades podem ser implementadas rotinas de auditoria mais complexas.

CONCLUSÃO

O sistema de chave eletrônica apresentou um resultado altamente satisfatório, mostrando que o *iButton* pode substituir o cartão magnético ou o código de barras na identificação de pessoas, pois é barato, extremamente resistente, pode entrar em contato com a água, e pode ser utilizado como um chaveiro, crachá ou anel. A instalação é simples, barata e pode-se usar computadores obsoletos para o controle, pois o programa foi desenvolvido em MS-DOS. Este sistema pode ser instalado em locais que necessitem de um certo controle de acesso, mas não disponham de funcionários para supervisão de pessoal. Este sistema poderá ser instalado em qualquer sala de nossa unidade universitária. Como exemplo, o PROIN-DEE que é um laboratório que dispõe de vários computadores e os alunos poderão acessá-lo em horários noturnos, quando não há funcionários disponíveis para controlar a entrada e saída do laboratório.

O sistema de chave eletrônica com o *iButton*, mostrou-se melhor que o de chave convencional, pois pode-se desabilitar um usuário se for necessário, pode-se usar um mesmo *iButton* para abrir várias portas diferentes e é possível criar várias rotinas de auditoria como o registro do horário de entrada, etc.

Os *iButtons* como um todo possuem inúmeras utilidades, pois cada um possui funções características, sendo que a chave eletrônica é apenas uma aplicação destas. A execução de projetos utilizando os *iButtons* depende apenas das necessidades do usuário e da criatividade do projetista.

AGRADECIMENTOS

BRANCH AND BOUND APLICADO NO PROBLEMA DE COBERTURA DE FUNÇÕES BOOLEANAS

Tercio Alberto dos Santos[1], Alexandre César Rodrigues da Silva[2] e Carlos Eduardo da Silva Santos[3]

Resumo *— Este trabalho apresenta um método para a obtenção de cobertura mínima para uma função booleana empregando o algoritmo Branch and Bound modificado. A partir da formulação do problema de cobertura de funções booleanas como um problema de programação linear inteira 0 e 1, cuja formulação é apresentada a seguir, a solução ótima global é obtida.*

MIN CT. X de modo que

$$AX \geq b$$
$$X \geq 0$$

Onde: $X \in Rn$; $C \in Rn$; $b \in Rn$ e $A \in R^{n.n}$ *com posto completo. Vários métodos para a geração de implicantes primos podem ser utilizados para a geração da formulação da cobertura. Empregou-se neste trabalho o algoritmo Expander que utiliza-se do método de expansão de Shannon. Uma grande variedades de funções booleanas foram estudadas, cujos resultados comprovaram a eficiência computacional deste tipo de abordagem. O algoritmo implementado em linguagem de programação está sendo comparado com outros algoritmos já implementados.*

Palavras chave — Programação Matemática, Otimização de Funções Booleanas, Branch and Bound, Plano de Corte, Dual Simplex.

INTRODUÇÃO

A otimização lógica a dois níveis tem suas raízes há muitas décadas atras e está baseada na teoria clássica sobre álgebra de chaveamento. Vários textos tratam do assunto [1], [2], [3]. Os primeiros algoritmos para a minimização exata foram propostos por Quine [4] e por McCluskey [2]. Uma grande variedade de métodos foram propostos ao longo dos anos como, por exemplo, o método de Rudell e Sangiovanni [5] denominado Espresso-Exact, o método de Dagenais et ali [6] denominado de McBoole, o método de Coudert e Madre [7] e muitos outros.

Com o aumento da complexidade dos circuitos digitais a minimização lógica exata tornou-se impraticável até algumas décadas atrás. Com o aumento da velocidade e da capacidade de memória das estações de trabalho, aliado ao desenvolvimento de eficientes métodos de cobertura para uma solução exata, revitalizou-se o interesse por essa área de pesquisa.

Atualmente, tem-se como um dos mais eficientes algoritmos de minimização de funções booleana o programa denominado BOOM (A Heuristic Boolean Minimizer) [8], cuja principal característica é a combinação da geração dos implicantes primos em conjunto com a solução do problema de cobertura, o que leva a uma redução no número de implicantes primos gerados.

Este trabalho trata sobre a resolução do problema de cobertura de funções booleanas formulada como um problema de programação matemática. Implementou-se três algoritmos descritos na literatura com o objetivo de avaliar o que melhor soluciona o problema de cobertura. Foram implementados o algoritmo Branch and Bound, o Plano de Corte de Gomory e o Dual Simplex. Utilizou-se como critério de eficiência a quantidade de memória utilizada, o tempo de execução, a quantidade de iterações e a solução obtida.

PROBLEMA DE COBERTURA

Toda cobertura mínima de uma função booleana é solução de um problema de programação linear inteira 0 e 1, dessa forma todos os avanços da área da programação matemática podem ser utilizados com o objetivo de solucioná-la. Muitos métodos clássicos podem ser empregados, porém nesse trabalho implementou-se três métodos, o Branch and Bound, o Plano de Corte de Gomory e o Dual Simplex Canalizado [9].

O método Simplex é a base para o Plano de Corte de Gomory e para o Branch and Bound. O Dual Simplex Canalizado é uma forma alternativa para solucionar o problema de cobertura sem a necessidade de se utilizar o método Simplex.

Resolver o problema de cobertura consiste em encontrar uma solução que satisfaça todas as restrições do problema e que o custo da função objetivo, que representa o custo de implementação da função booleana, seja o menor possível.

Na grande maioria dos exemplos tratados neste trabalho obteve-se solução inteira no conjunto binário 0 e 1. Contudo, em alguns casos encontrou-se uma solução otimista (casos cíclicos). A identificação de casos cíclicos tornou-se possível, pois a solução é fracionária. Para esses casos empregou-se o método Branch and Bound ou Plano de Corte

de Gomory para encontrar a solução ótima global do problema.

O algoritmo de Branch and Bound é um algoritmo enumerativo, cuja estrutura de resolução baseia-se na construção de uma árvore onde os nós representam os problemas candidatos e os ramos representam as novas restrições que devem ser consideradas. Por intermédio dessa árvore, todas as soluções inteiras da região viável do problema são enumeradas de modo implícito ou explicito o que garante que todas as soluções ótimas serão encontradas.

O algoritmo de Plano de Corte [10] é um dos principais algoritmos de programação linear inteira, o seu uso é pós otimização de PL internamente. Nesse algoritmo de uma iteração para outra resolve-se um PL com uma restrição adicional. Assim, os PL's sucessivos são diferentes em uma restrição adicional. Portanto, a estratégia mais evidente é usar dual simplex que aproveita o quadro ótimo de um PL para resolver o PL seguinte com a simples adição no quadro da nova restrição corretamente atualizada para a base atual.

O algoritmo dual simplex canalizado é o mais adequado para reotimizar subproblemas de programação linear (PL) gerados pelos algoritmos de Branch and Bound na resolução de um problema de programação linear inteira.

No algoritmo de Branch and Bound cada problema (PL) é diferente de seu antecessor em uma restrição adicional da seguinte forma:

$$x_j \geq k + 1 \qquad (\beta_1)$$

ou

$$x_j \leq k \qquad (\beta_2)$$

Sendo k um número inteiro.

Embora as restrições do tipo β_1 e β_2 podem ser adicionadas como uma restrição padrão e usar um algoritmo dual simplex padrão, essa estratégia aumenta sem necessidade o tamanho do quadro e da base. Como as restrições β_1 e β_2 são restrições sobre uma única variável então a melhor estratégia é usar um algoritmo dual simplex canalizado que leva em conta esse tipo de restrições somente de maneira implícita.

Vários métodos podem ser empregados para a formulação do problema de cobertura. Neste trabalho utilizou-se o algoritmo Expander [11] que implementa Método de Expansão de Shannon.

O Método de Expansão de Shannon

A geração de implicantes primos pelo Método de Expansão de Shannon é uma técnica iterativa que permite obter implicantes primos de uma dada função boolena através de simples operações sobre o conjunto de mintermos e/ou estados "don't care", representados em notação decimal, que descreve a função original. Tal método pode ser empregado em função com um grande número de variáveis. Todos ou, quase todos os implicantes primos que não estariam no conjunto solução são eliminados, simplificando, desse modo, a busca pela solução mínima.

Como exemplo considere a função booleana f(A,B,C,D) = $\Sigma m(0, 6, 8, 10, 15) + d(1, 2, 7, 9, 11, 14)$. Para a formulação do problema de cobertura utilizou-se o algoritmo Expander cujo arquivo de entrada e de saída estão apresentados na Figura 1 e na Figura 2, respectivamente. A tabela de cobertura proposta por McCluskey, consiste de colunas contendo todos os mintermos da função e de linhas que representam todos os implicantes primos gerados. A Tabela I apresenta a tabela de cobertura de McCluskey cujos implicantes primos foram gerados pelo algoritmo Expander.

Com o auxílio da Tabela I, o problema de cobertura dos mintermos transforma-se em um problema de programação linear inteiro binário 0 e 1.

FIGURA. 1
TELA DO ARQUIVO DE ENTRADA DO PROGRAMA EXPANDER.

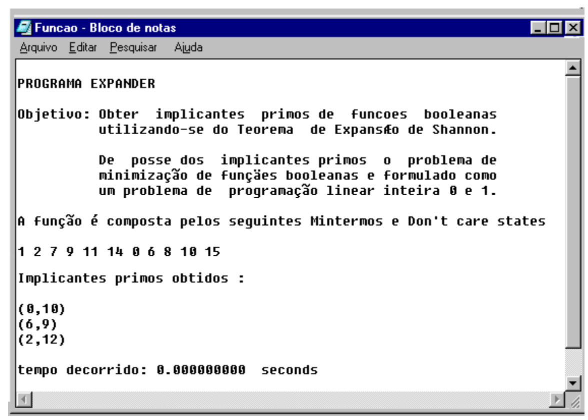

FIGURA. 2
TELA DO ARQUIVO DE SAÍDA DO PROGRAMA EXPANDER.

TABELA I
TABELA DE COBERTURA DE MCCLUSKLEY CUJOS IMPLICANTES PRIMOS FORAM GERADOS PELO ALGORITMO EXPANDER

	Mintermos				
Implicantes	0	6	8	10	15
XX10		x		x	
1X1X				x	x
X11X		x			x
X00X	x		x		

Optou-se por tratar o problema de cobertura como um problema matemático. Dessa forma, empregou-se uma notação matemática mais simples.

Fazendo-se: x_1 = XX10 , x_2 = 1X1X, x_3 = X11X e x_4 = X00X o problema apresentado na Tabela I é formulado como um problema de programação linear inteira 0 e 1 como descrito a seguir [12]:

$$
\begin{aligned}
&\min x_0 = 3x_1 + 3x_2 + 3x_3 + 3x_4 \\
&\text{s.a.} \\
&x_1 + x_2 \geq 1 \\
&x_1 + x_3 \geq 1 \\
&x_2 + x_3 \geq 1 \\
&x_4 \geq 1 \\
&x_1, x_2, x_3, x_4 \in \{0, 1\}
\end{aligned}
$$

Na resolução deste problema de programação linear usou-se uma linguagem de programação [13] MATLAB 5.3, que foi implementado em duas etapas:

a) Fez-se um programa para resolver o problema pelo método Simplex e obteve-se uma solução otimista, apresentado na Tabela II.

TABELA II
SOLUÇÃO OTIMISTA PELO MÉTODO SIMPLEX

7.5000	-1.5000	-1.5000	-1.5000	-3.0000
0.5000	-0.5000	-0.5000	0.5000	0
0.5000	-0.5000	0.5000	-0.5000	0
0.5000	0.5000	-0.5000	-0.5000	0
1.0000	0	0	0	-1.0000

O valor da função objetivo é igual a 7.5000, os valores da coluna abaixo do valor da função objetivo são os valores das variáveis, ou seja, {(0.5000, 0.5000, 0.5000, 1.0000)};

b) A solução da primeira etapa é otimista, então, implementou-se o programa (Branch2) empregando o dual simplex canalizado, assim, dando seqüência na resolução do método Branch and Bound.

No desenvolvimento do problema tem-se dois subproblemas P_1 e P_2.

Resolução do subproblema P_1

Para resolver o subproblema P_1 acrescentou-se uma restrição representado na Tabela III.

TABELA III
SOLUÇÃO OTIMISTA COM ACRÉSCIMO DA RESTRIÇÃO

7.5000	-1.5000	-1.5000	-1.5000	-3.0000
0.5000	-0.5000	-0.5000	0.5000	0
0.5000	-0.5000	0.5000	-0.5000	0
0.5000	0.5000	-0.5000	-0.5000	0
1.0000	0	0	0	-1.0000
-0.5000	-0.5000	0.5000	0.5000	0

Implementou-se o programa Dual Simplex Canalizado e encontrou-se como solução ótima global da função booleana apresentada na Tabela IV.

O valor da função objetivo é igual a 9 e os valores da coluna abaixo do valor da função objetivo são os valores das variáveis, ou seja, o conjunto verdade {(1, 0, 1, 1, 1)}.

TABELA IV
SOLUÇÃO ÓTIMA DO SUBPROBLEMA P_1

9	0	-3	-3	-3
1	0	-1	0	0
0	-1	1	0	0
1	1	-1	-1	0
1	0	0	0	-1
1	1	-2	-1	0

Resolução do subproblema P_2

Para resolver o subproblema P_2 adicionou-se uma nova restrição e implementou-se o programa Dual Simplex Canalizado e obteve-se como solução ótima do problema de cobertura mínima da função booleana *f*(A,B,C,D) = Σm(0, 6, 8, 10, 15) + d(1, 2, 7, 9, 11, 14) representado na Tabela V.

TABELA V
SOLUÇÃO ÓTIMA DO SUBPROBLEMA P_2

9	-3	-3	-3	-3
0	0	0	1	0
1	-1	0	-1	0
1	0	-1	-1	0
1	0	0	0	-1
1	-1	-1	2	0

A solução ótima do subproblema P_2, é o valor da F.O = 9 (função objetivo) e os valores das variáveis é o conjunto verdade {(0, 1, 1, 1, 1)}.

Observa-se que em ambos os subproblemas P_1 e P_2 o custo da função booleana *f*(A,B,C,D) = Σm(0, 6, 8, 10,15) + d(1, 2, 7, 9, 11, 14) é F.O. = 9.

Outros algoritmos foram implementados neste Exemplo na linguagem de programação MATLAB 5.3 e o valor obtido em ambos os casos foi o mesmo para função booleana *f*(A,B,C,D) = Σm(0, 6, 8, 10, 15) + d(1, 2, 7, 9, 11, 14).

Implementação do Algoritmo Dual do Simplex

Partindo-se do quadro otimista implementa-se o algoritmo Dual Simplex na linguagem de programação (MATLAB 5.3), e obtém-se como resultado:

FO = 9, X2 = 1, X3 = 1, X7 = 1 e X4 = 1

Assim, a solução ótima global do problema de cobertura da função booleana *f*(A,B,C,D) = Σm(0, 6, 8, 10,15) + d(1, 2, 7, 9, 11, 14) é dada por: custo mínimo igual a 9, e o conjunto verdade {(0, 1, 1, 1, 0, 0, 1)}, embora em ambos casos os conjuntos verdades sejam diferentes, porém, o custo é o mesmo.

Implementação do Algoritmo Plano de Corte ou Algoritmo de Gomory.

Partindo-se do quadro otimista da Tabela II encontrado pelo algoritmo Simplex, e acrescenta-se uma restrição de corte tem-se a Tabela VI, para depois implementar o algoritmo de Gomory (Gomo2) na linguagem de programação MATLAB 5.3.

TABELA VI
ACRÉSCIMO DE UMA NOVA RESTRIÇÃO NO QUADRO OTIMISTA

7.5000	-1.5000	-1.5000	-1.5000	-3.0000
0.5000	-0.5000	-0.5000	0.5000	0
0.5000	-0.5000	0.5000	-0.5000	0
0.5000	0.5000	-0.5000	-0.5000	0
1.0000	0	0	0	-1.0000
-0.5000	0.5000	-0.5000	-0.5000	0

Implementando o algoritmo de Gomory (Gomo2) tem-se a apresentação da Tabela VII a qual apresenta a solução ótima do problema.

TABELA VII
SOLUÇÃO ÓTIMA PELO MÉTODO DE GOMORY

9	-3	0	0	-3
1	-1	0	1	0
1	-1	1	0	0
0	1	-1	-1	0
1	0	0	0	-1
1	-2	1	1	0

A função objetivo FO = 9 e os números que aparecem na coluna abaixo do número 9 são os valores das variáveis, ou seja, o conjunto verdade {(1, 1, 0, 1, 1)}.

Comparando-se as três implementações obteve-se o conjunto de soluções diferentes, porém com o mesmo custo, ou seja, em todos os casos a solução mínima global da função booleana $f(A,B,C,D) = \Sigma m(0, 6, 8, 10,15) + d(1, 2, 7, 9, 11, 14)$ tem o custo igual a 9. Assim, obteve-se parâmetros para os três algoritmos implementados para relacionar custos, números de iterações, tempo computacional e quantidades de memórias, apresentados na Tabela VIII. Os resultados obtidos são:

TABELA VIII
APRESENTAÇÃO DA ANÁLISE DOS ALGORITMOS BRANCH2, GOMO2 E DUAL

Program	Custo	Iteração	Tempo(seg)	Mem.(bytes)
Branch2	9	6	2,56	2.772
Gomo2	9	5	2,09	2.448
Dual	9	3	0,77	1.780

As Figuras 3, 4 e 5, respectivamente, apresentam a relação gráfica das iterações, tempo gasto em segundos e memória em bytes dos três algoritmos implementados.

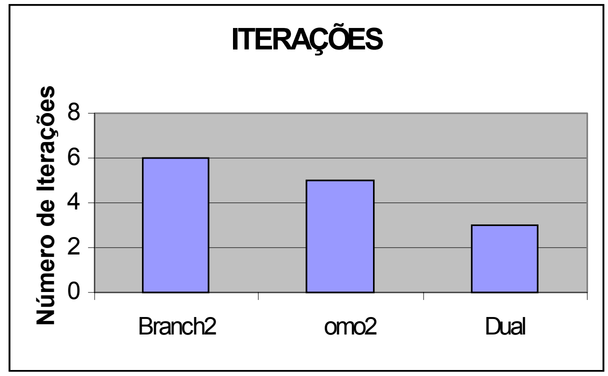

FIGURA. 3
APRESENTA AS ITERAÇÕES GASTAS PELOS PROGRAMAS BRANC2, GOMO2 E DUAL.

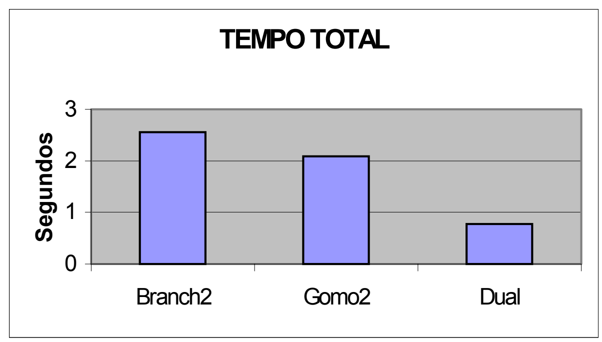

FIGURA. 4
APRESENTA O TEMPO GASTO PELOS PROGRAMAS BRANC2, GOMO2 E DUAL.

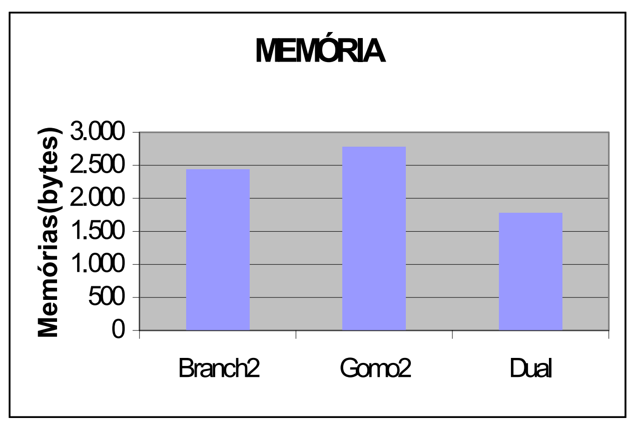

FIGURA. 5
APRESENTA A QUANTIDA DE MEMÓRIAS GASTA PELOS PROGRAMAS BRANC2, GOMO2 E DUAL.

CONCLUSÃO

Os circuitos elétricos são representados matematicamente pelas funções booleanas e neste trabalho revolveu-se a função booleana f(A,B,C,D) = Σm(0, 6, 8, 10,15) + d(1, 2, 7, 9, 11, 14) como exemplo. Através do algoritmo Expander, que utiliza-se do método de expansão de Shannon, gerou-se os implicantes primos as funções e o problema de cobertura foi modelado como um problema de programação matemática.

Visto que todo problema de cobertura mínima de uma função booleana é solução de um problema de programação linear inteira 0 e 1, implementou-se o algoritmo de Branch and Bound e encontrou-se a solução ótima global do problema de cobertura mínima.

Comparando-se com a implementação de outros algoritmos como Plano de Corte de Gomory e Dual Simplex observou-se que os três algoritmos implementados encontram o mesmo custo. A análise da Tabela II mostra os parâmetros entre os programas Branch2, Gomo2 e Dual quanto ao número de iterações, quantidade de memórias e o tempo em segundos gastos na execução de cada programa. Chega-se a conclusão que entre os três programas implementados o Dual leva uma ligeira vantagem, pois tem um número menor de iterações, o tempo gasto para executar o programa é menor comparando com os outros dois e a quantidade de memórias é bem menor.

Muito outros casos de cobertura estão sendo avaliados com o objetivo de validar os algoritmos implementados.

AGRADECIMENTOS

Os autores agradecem a Direção da Fundação do Ensino Superior de Rio Verde "FESURV" e a CAPES, pelo apoio irrestrito dado as pesquisas realizadas no desenvolvimento deste trabalho.

SEQ2VHDL - Um Ambiente para Projeto de Sistemas Digitais

Leandro de Oliveira Tancredo[1], *Alexandre César Rodrigues da Silva* [2] *e Norian Marranghello* [3]

Resumo — *Este trabalho apresenta uma nova ferramenta de síntese para projetos de sistemas digitais denominada SEQ2VHDL. A partir da descrição em diagrama de transição de estados de uma máquina de estados finitos, representada no modelo de Mealy, é gerado uma descrição otimizada do sistema na linguagem de hardware VHDL. Elimina-se dessa forma a tarefa árdua com detalhes d projeto. A SEQ2VHDL foi comparada com duas outras ferramentas disponíveis comercialmente. Foram projetados diversos chip-set de códigos de transmissão digital utilizados no setor de telecomunicações. Os resultados comprovaram o desempenho satisfatório com relação ao custo de implementação, ao tempo de execução e uso de memória. A ferramenta trará grandes contribuições nas áreas educacionais da engenharia elétrica e computação, possibilitando além da criação de sistemas autômatos, o aprendizado da linguagem VHDL, pois trata-se de uma ferramenta de domínio público ao contrário das ferramentas comerciais.*

Palavras Chave: FPGA, VHDL, FSM, HDL, Síntese Lógica).

INTRODUÇÃO

Este artigo tem como proposta apresentar uma ferramenta de síntese de alto nível ou HLS (abreviatura do inglês *high-level synthesis*) denominada SEQ2VHDL (SEQUENCIAL TO VHDL) e, a partir, dela implementar vários circuitos integrados de códigos de linhas utilizados em transmissão de dados, no setor de telecomunicações, originados a partir do diagrama de estados, utilizando a linguagem VHDL [2] [8][9]. Criou-se, dessa forma, um ambiente compatível para a síntese de sistemas digitais que veio facilitar a tarefa do projetista, eliminando a descrição detalhada como no exemplo de uma metodologia de projetos digitais seqüenciais apresentada em [10].

Atualmente, dispõe-se de dois importantes tradutores disponíveis comercialmente que interpretam uma máquina de estado finito, descrita através de seu diagrama de estado. Estas ferramentas são denominadas: Statecad [11] da Actel e Active-HDL [4], da Cypress.

Esses *softwares* destacam-se pelo uso do diagrama de estados para descrever o comportamento de uma máquina de estados finitos, traduzindo-as para a sua representação em código VHDL. Nenhum processo de otimização é efetuado nesta etapa, deixando a cargo das ferramentas de síntese, ou seja, o MAX + Plus II [1] ou XILINX [12]. Estas ferramentas apresentam entradas gráficas que possibilitam expressar idéias em um modo natural, bem próximo da linguagem humana.

Como a descrição em VHDL independe da tecnologia, as ferramentas de síntese comerciais apropriadas levariam para o nível de implementação de estado no domínio físico.

Conforme GENOE [7] existem aproximadamente 6000 licenças para sintetizadores lógicos no mercado, entretanto, há uma carência de ferramentas que interpretem os níveis de abstração altos. Um tradutor de linguagem, foi proposto por BONATTI [3] e implementado em um pacote de domínio público, denominado Stoht. FUHRER et alli [6] descrevem uma solução para minimização de estados de uma FSM para circuitos lógicos.

Muitas outras ferramentas de síntese de Alto Nível são descritas na literatura, comprovando a importância deste tipo de abordagem.

Na próxima seção, descreve-se os programas TABELA e o SEQ2VHDL.

AMBIENTE TABELA E SEQ2VHDL

Descreve-se nesta seção um método sistemático para projetos que a partir de uma descrição textual de uma máquina de estados finitos síncronas, origina-se uma segunda descrição, onde os elementos de memória são claramente identificáveis (*flip-flops*) e, finalmente, uma última descrição em VHDL na qual está presente uma entrada particular, denominada relógio.

Programa TABELA

O programa TABELA [5] resultado de trabalho de tese apresentado na UNICAMP possui as seguintes etapas do projeto conforme a Figura 1.

Na metodologia empregada parte-se do nível RTL do domínio comportamental e chega-se ao nível lógico do mesmo domínio, ou seja, parte-se do diagrama de estados e chega-se nas correspondentes funções booleanas e memórias em suas formas mínimas. Vários algoritmos de minimização de funções booleanas poderiam ser empregados nesta etapa do projeto, optou-se pelo método Quine-McCluskey [5].

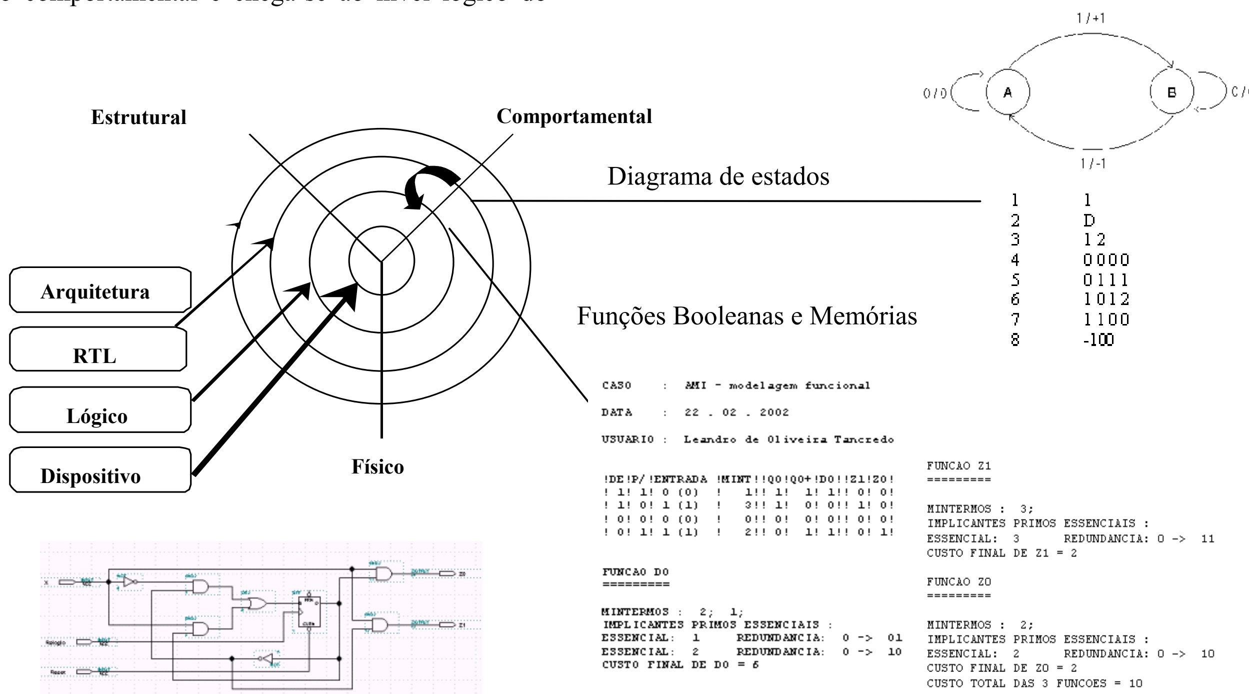

FIGURA. 1
DIAGRAMA Y APRESENTANDO A FERRAMENTA TABELA.

Programa SEQ2VHDL

Nesta seção descreve-se a ferramenta SEQ2VHDL, que recebe como entrada as funções booleanas (a saída gerada pelo programa TABELA) e cria um modelo funcional do circuito descrito na linguagem de descrição VHDL, conforme a figura 2 que apresenta o diagrama Y.

A listagem abaixo descreve o arquivo AMI.VHD gerado pelo programa SEQ2VHDL:

```
-- Ferramenta de Síntese Lógica
-- A ferramenta tem por objetivo transformar a descrição -
-- de uma máquina de estados finitos
-- sintetizada pelo programa TABELA para o seu modelo
-- RTL descrito em VHDL.
-- Programa: SEQ2VHDL.EXE
-- Programador: Leandro de Oliveira Tancredo
-- Versão: 9.0 de 3 de março de 2002
ENTITY AMI IS
    PORT(
-- CLK e CLR estão presentes em todos os modelos
    CLK, CLR : IN BIT;
-- Os parâmetros seguintes são definidos de acordo

```

© 2003 ICECE

```
-- no arquivo gerado pelo Programa TABELA
SIGNAL D0 : BIT;
 BEGIN
-- Nesta parte do modelo tem-se a descrição de cada um dos Flip-flops.
--Deve-se observar que os sinais auxiliares são utilizados,
-- sendo que no final de cada processo seus valores são
--transferidos para as variáveis de estados
-- Importante salientar que em relação ao software, existem duas procedures,
-- uma que implementa o flip-flop D e outra que
--implementa o JK e estas procedures recebem os índices
-- que representam o respectivo elemento de memória.
--Tais índices estão definidos no arquivo gerado pelo
 --programa TABELA
-- Inferindo flip-flop tipo D
PROCESS(CLK, CLR)

BEGIN
   IF CLR = '0' THEN
      VE0 <= '0';
   ELSIF CLK'EVENT and CLK = '1' THEN
      VE0 <= D0;
   END IF;
   Q0 <= VE0;
END PROCESS;
-- Processos que implementam as funções combinacionais de controle
-- dos Elementos de memória e de Saídas.
  D0 <=  ( NOT(X0) AND (VE0)) OR ((X0) AND NOT(VE0));
  Z1 <=  ( (X0) AND (VE0));
  Z0 <=  ( (X0) AND NOT(VE0));
END RTL;
```

Pode-se notar que na entidade do modelo apresentado foram definidos os portos de entrada e saída e os sinais de sincronismo (CLK e CLR). O porto denominado Q_0 não é necessário para o perfeito funcionamento do sistema. Este foi inserido para permitir que o projetista observe, através de simulação, os estados pelos quais a máquina está transitando. Cabe salientar que o TAB2VHDL foi desenvolvido para ser empregado no ensino de sistemas digitais. Se a avaliação das transições de estado não forem necessárias, as variáveis de estado podem ser omitidas.

São definidos sinais auxiliares denominados V_{En} cujo objetivo é evitar que se gerem vários *drivers* para um mesmo sinal, o que exigiria o desenvolvimento de uma função de resolução. Esta função define qual será o valor do sinal em caso de conflitos.

É criado um processo para cada um dos *flip-flops* utilizados. Dois tipos de processos foram criados, um para modelar *flip-flop* D, sensível a transição de subida, e o outro para modelar *flip-flop* JK, sensível a transição de subida. Vários outros modelos de *flip-flop* poderiam ser definidos na ferramenta SEQ2VHDL.

Por fim, são definidas as funções de controle dos elementos de memória, D_0, e de saída, Z_1 e Z_2.

Estas funções foram obtidas do arquivo gerado pelo programa TABELA.

Na simulação apresentada na figura 2, verifica-se o perfeito funcionamento do código AMI, cujo modelo foi gerado pelo programa SEQ2VHDL.

Vários códigos de linhas foram projetados, empregando três diferentes ambientes de projeto. Na próxima seção, ao implementar os códigos, compara-se o projeto gerado pelo SEQ2VHDL com outras ferramentas.

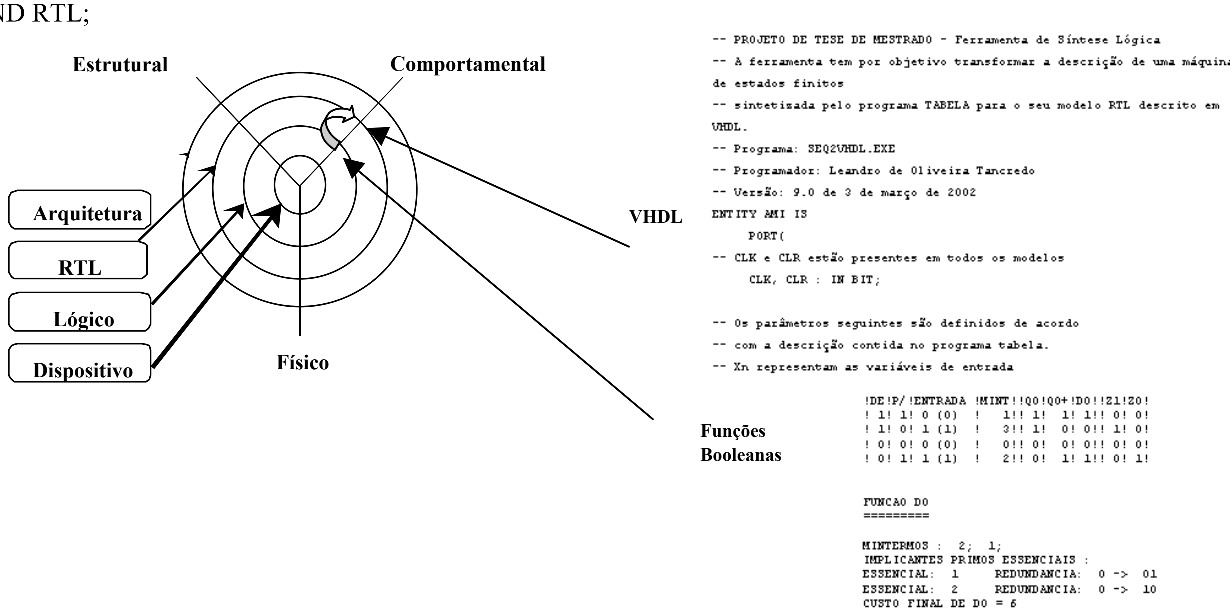

FIGURA. 2
DIAGRAMA Y QUE REPRESENTA A FERRAMENTA SEQ2VHDL.

ESTUDO DE CASOS

Escolheu-se para estudo de casos a implementação de alguns chip-sets de códigos de transmissão digitais, utilizando-se duas ferramentas e o ambiente TABELA + SEQ2VHDL. A maioria desses exemplos são padrões, todavia, com o passar do tempo surgem novos serviços, que obrigam a adaptação do código à nova tecnologia utilizada.

Logo, os projetos devem permitir uma maior flexibilidade de adaptação, sendo que uma solução adequada seria a implementação em *software*. Contrariamente, por estes códigos estarem localizados nas camadas inferiores da OSI/ISO, e, por isso, necessita-se de velocidade nas suas aplicações em tempo real, adotando-se a implementação em *hardware*.

O desenvolvimento de projetos eletrônicos tem impulsionado o setor de telecomunicações nos últimos anos, permitindo, assim, a criação de vários serviços digitais, como exemplo, temos várias tecnologias RDSI, HDSL, ADSL, VDSL e várias outras que estão surgindo no mercado. A utilização de componentes lógicos programáveis, como FPGAs para implementação de hardware, têm proporcionado uma melhoria no desempenho do circuito, ou seja, a redução de custos e uma integração física maior em relação aos projetos convencionais.

Os códigos de linha HDB3, HDB1, 2BQ1, 3B4B, MLT-3, AMI e algumas técnicas alternativas de detecção de sincronismo foram projetados utilizando-se as ferramentas comerciais, aqui denominadas simplesmente de SC e AC, e os resultados foram comparados com os obtidos pelo ambiente TAB2VHDL, conforme Tabela I.

TABELA I

Pode-se concluir através da análise das tabelas apresentadas que o ambiente TABELA em conjunto com SEQ2VHDL obteve um desempenho notável comparado com as ferramentas avaliadas.

Outro resultado importante, foi obtido ao comparar o custo do código gerado pelo TAB2VHDL ao utilizar como elemento de memória flip-flop JK (TAB JK) ou D (TAB D), observa-se conforme Tabela II que em algumas situações o JK é a melhor solução como no 2BQ1, 3B4B e MLT3, e que em outras o D foi a melhor solução como na AMI, S10010 E CCS.

CONCLUSÃO

Conclui-se que com o surgimento de novos serviços, que deverão em um curto espaço de tempo, serem projetados e adaptados, impulsionados pelos grandes resultados apresentados pelo desenvolvimento das tecnologias digitais, como exemplo, o HDSL que a partir de um único cabo de par trançado se compartilha 30 canais de voz em um link de 2 Mbps, substituindo um único canal de voz analógico como nas tecnologias passadas. Portanto, a necessidade de novas ferramentas de síntese como o TAB2VHDL, para otimizar *chip-sets* envolvidos nestes tipos de projetos, passa a ter fundamental importância.

Assim, o estudo mostrou que é impossível ter uma única ferramenta que substitua todas as outras, entretanto, se existisse, ficaria muito complicado trabalhar, tendo como causa o alto grau de complexidade que envolveria o projeto.

O projeto de sistemas digitais é uma área de pesquisa em constante evolução. O aumento contínuo da complexidade dos sistemas, cria a necessidade de se rever as técnicas de síntese e otimização já desenvolvidas.

O emprego cada vez maior das FPGAs tem motivado o desenvolvimento de ferramentas de síntese automatizada.

AGRADECIMENTOS

Os autores agradecem ao PPGEE da FEIS – UNESP, UNIFEV, FAI-JALES, à CAPES e à P.I. Componentes.

VIABILIZANDO LABORATÓRIOS DE APOIO A PESQUISA NO PROGRAMA DE MESTRADO EM TELECOMUNICAÇÕES DO INATEL

Luciano Leonel Mendes[1], Maurício Silveira[2], Wilton Ney do Amaral Pereira[3]
José A. Justino Ribeiro[4], Adonias Costa da Silveira[5]

Resumo *— O objetivo deste artigo é poder comprovar a eficiência no aprendizado dos alunos de um programa de pós-graduação "stricto sensu" dependendo dos recursos laboratoriais implementados, e as conseqüências diretas na qualidade dos trabalhos de tese apresentados. Restringiu-se a apresentação de somente dois roteiros laboratoriais desenvolvidos pelos alunos relativos a conceitos de fundamental importância dentro da área de sistemas de comunicação. Este trabalho tem proporcionado uma melhor sedimentação por parte dos alunos dos conceitos teóricos apresentados nos cursos do programa. Entre os equipamentos mais importantes usados no laboratório pode-se destacar: modulador de sinais genéricos SMIQ, analisador vetorial de sinais FSIQ, analisador espectral e de redes e osciloscópios digitais de faixa larga. O laboratório conta também com rádios digitais Microstar 7,5GHz , 18 GHz e Aurora 2,4 GHz para ensaios com equipamentos em condições opera-cionais. Essa associação de instrumentos e equipamentos permite realizar testes nas mais diversas condições, possibilitando estudar novas configurações, determinar suas limitações e buscar inovações na área de sistemas de comunicações.*

Palavras Chave — Medidas Experimentais, Modulação de Sinais, Análise Espectral, e Análise de Sinais.

INTRODUÇÃO

Neste artigo serão abordados dois roteiros laboratoriais de extrema utilidade na análise dos sistemas de comunicações digitais. O primeiro deles trata dos diversos tipos de espalhamento espectral, sendo que em cada exemplo citado é apresentado um diagrama em blocos completo do hardware que está sendo estudado. Neste roteiro, o aluno realiza um levantamento do desempenho do sistema DS-SS (*Direct Sequence Spread Spectrum*) [1] perante a interferências propositais de faixa estreita e de faixa larga. O segundo roteiro apresenta um estudo minucioso do modulador complexo em fase e quadratura (IQ), abordando as influências do filtro cosseno elevado, do ruído AWGN (*Additive White Gaussian Noise*) [2], e dos múltiplos percursos [3] no sinal transmitido. Estas análises são realizadas tanto no domínio do tempo quanto no domínio da freqüência, abordando também uma análise do diagrama da constelação recebida e do diagrama de olho.

ESPALHAMENTO ESPECTRAL

A técnica de espalhamento espectral foi desenvolvida primordialmente para permitir comunicações militares com grande robustez a interferências propositais, prática muito comum em tempos de guerra. Porém, as características desta técnica de comunicação acabou por demonstrar uma grande vantagem para o uso comercial, pois permitiu um novo método de múltiplo acesso ao canal de comunicação: o múltiplo acesso por divisão por código (CDMA – *Code Division Multiple Access*) [1].

A literatura aborda a existência de três técnicas de espalhamento espectral, cabendo destacar: Espalhamento Espectral por Seqüência Direta, Espalhamento Espectral por Salto em Freqüência, e Espalhamento Espectral por Salto no Tempo.

Espalhamento Espectral por Seqüência Direta

A técnica de espalhamento espectral por seqüência direta representa um dos principais segmentos no estudo de espalhamento espectral, devido a sua aplicação no padrão de telefonia celular CDMA, padronizada pelo IS-95 [4]. Nesta técnica, os bits de dados são multiplicados por uma seqüência pseudo aleatória (*PN*) de comprimento *N*. A taxa da seqüência *PN* (taxa de *chip*, *Rc*) é muito maior do que a taxa de bit (*Rb*). Desta forma, o espectro do sinal de saída ocupa uma largura de faixa muito maior do que a largura de faixa ocupada pelo sinal original.

Após o canal, o sinal recebido deve ser multiplicado pela seqüência *PN* em fase, para que o sinal possa ser recuperado. Caso as seqüências estejam defasadas, o sinal não é recuperado sendo interpretado como ruído pelo circuito de decisão. A Figura 1 mostra o diagrama em blocos de um sistema *DS-SS* em banda básica. Utilizando os rádios digitais *DS-SS* em conjunto com o Modulador Digital SMIQ [5] é possível levantar o desempenho desta técnica perante interferências intencionais de faixa larga e de faixa estreita.

FIGURA 2
DIAGRAMA EM BLOCOS DE UM SISTEMA DE TRANSMISSÃO *FH-SS*

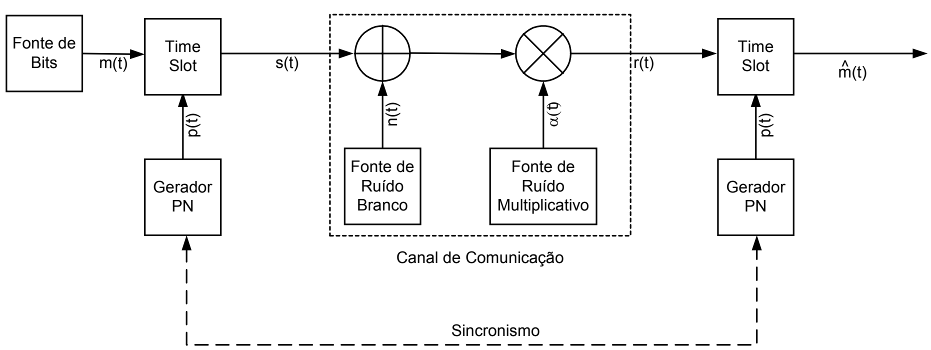

FIGURA 3
DIAGRAMA EM BLOCOS DE UM SISTEMA DE TRANSMISSÃO *TH-SS*

Espalhamento Espectral por Salto em Freqüência

O Espalhamento Espectral por Salto em Freqüência (*FH-SS Frequency Hope Spread Spectrum*) [1] representa outra técnica de espalhamento espectral que vem sendo bastante utilizada para transmissão de sinais digitais em meios perturbados. Neste caso, o Oscilador Controlado por Tensão (*VCO*) tem sua freqüência de operação definida por uma seqüência *PN*, ou seja, a cada instante de tempo, a freqüência utilizada para modular o sinal a ser transmitido é definida por uma seqüência *PN*. A Figura 2 mostra o diagrama básico para a transmissão e recepção de um sinal *FH-SS*.

Espalhamento Espectral por Salto no Tempo

O Espalhamento Espectral por Salto no Tempo (*SS-TH*) [1] é a ultima das técnicas de importância referenciada neste artigo. Neste tipo de sistema, o slot de tempo que o usuário ocupa em cada quadro é definido por uma seqüência *PN*. A Figura3 mostra um diagrama básico para este sistema.

Os sistemas de transmissão que utilizam técnicas de espalhamento espectral possuem um melhor desempenho referente a interferências propositais. Esta melhoria de desempenho é denominada de Ganho de Processamento (*Gp*). Utilizando os recursos do laboratório, os alunos podem co-rroborar os resultados teóricos com as medidas práticas realizadas. O objetivo com este experimento é explorar o sistema *DS-SS*, pois esta é a técnica utilizada por um dos rádios digitais que o laboratório possui. Com este sistema, vários usuários utilizam a mesma faixa espectral ao mesmo tempo. Isso é possível pois cada usuário possui um código de espalhamento único, ou seja, cada usuário utiliza uma seqüência de espalhamento conhecida apenas pelo transmissor e pelo receptor.

Uma das grandes vantagens que pode-se observar é que este tipo de analise das técnicas de espalhamento espectral pode ser adotado utilizando diferentes tipos arquiteturas de rádios digitais, além de verificar o desempenho contra interferências intencionais de faixa estreita e ruído de faixa larga.

MODULAÇÃO DIGITAL COMPLEXA

As técnicas de modulação digital que transportam os bits de informação na fase e/ou na amplitude de uma portadora podem ser representadas através de um diagrama vetorial chamado de Diagrama de Constelação ou simplesmente Constelação [2]. Este diagrama utiliza bases ortogonais para representar os símbolos da modulação em um plano vetorial. A base desse plano é constituída pelas funções seno e cosseno, pois estas funções respeitam o princípio de ortogonalidade, dado por :

$$\int_0^T \mathrm{sen}(\omega_o t)\cdot\cos(\omega_o t)dt = 0 \qquad (1)$$

onde ω_o é a freqüência angular da portadora e T é o período da portadora.

Desta forma, qualquer modulação que utilize variações de fase e de amplitude podem ser representadas neste plano. A Figura 4 mostra a constelação de um sinal *QPSK* (*Quadrature Phase Shift Keying*) [3].

Os vetores que terminam nos vértices do quadrado pontilhado representam os símbolos que compõe a modulação. A circunferência pontilhada possui raio $\sqrt{E_s}$, onde E_s é a energia do símbolo. Fazendo a projeção dos símbolos nos eixos, é possível perceber que cada símbolo da constelação pode ser representado por coordenadas cartesianas. Sendo assim, o sinal modulado pode ser obtido através de dois sinais; um modulando a portadora em fase e outro modulando a portadora defasada de 90° (*sinal em quadratura*). Desta forma, os sinais *I* (*In Phase*) e *Q* (*Quadrature*) definem quais são os símbolos transmitidos ao longo do tempo e representam o sinal modulado em banda-básica. A Figura 5 mostra como obter modulação *QPSK* utilizando a representação vetorial.

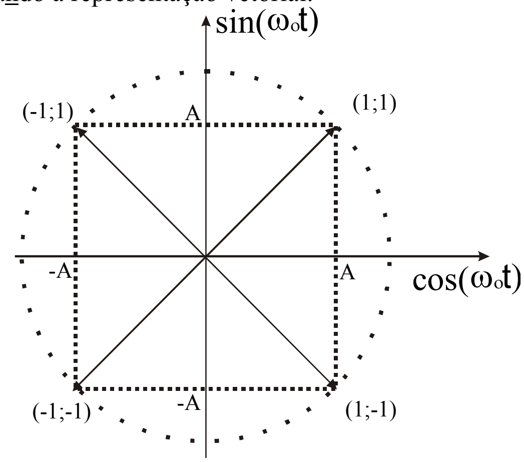

FIGURA 4
CONSTELAÇÃO QPSK

A Figura 5a mostra uma seqüência de bits à ser transmitida enquanto que a Figura 5b mostra os sinais *I* e *Q* obtidos a partir dos bits de entrada. Observando a projeção dos símbolos nos eixos na Figura 4, pode-se concluir que um sinal *QPSK* nada mais é do que a soma vetorial de dois sinais *BPSK*. Por este motivo, os sinais *I* e *Q* são sinais binários que assumem os valores +A ou –A. Como cada símbolo representa dois bits, o período dos sinais *I* e *Q* é duas vezes maior do que o período do sinal de entrada. De uma maneira geral, pode-se definir que o tempo de símbolo de um sistema *M-ário* como:

$$T_s = \log_2(M)\cdot T_b \qquad (2)$$

Onde T_s é o tempo de símbolo, M é a ordem da modulação em fase e quadratura e T_b é o tempo de bit do sinal a ser transmitido.

A Figura 5c mostra um modulador vetorial, onde o sinal *IQ* em banda-básica é translado para a freqüência de canal. O sinal *I* é modulado utilizando a função cosseno e o sinal *Q* é modulado utilizando a função seno. A soma vetorial desses sinais gera o sinal *QPSK*, representado através de uma portadora com quatro fases distintas. O princípio mostrado aqui pode ser extrapolado para gerar sinais *M-PSK* (M – *Phase Shift Keying*) e *M-QAM* (*M – Quadrature Amplitude Modulation*), alterando apenas a lei de formação do sinais *I* e *Q*. Desta forma é possível construir um modulador digital genérico, mudando apenas o mapeador *IQ*. No caso do *SMIQ* o mapeador *IQ* é implementado utilizando *DSP* com um programa que permite selecionar o tipo de modulação desejada.

Esta experiência permite ao aluno explorar os recursos do modulador digital genérico *SMIQ* e do analisador de sinais *FSIQ* [6] para verificar o princípio de funcionamento da

© 2003 ICECE

modulação digital, além de estudar a influência dos filtros e do canal no sinal modulado.

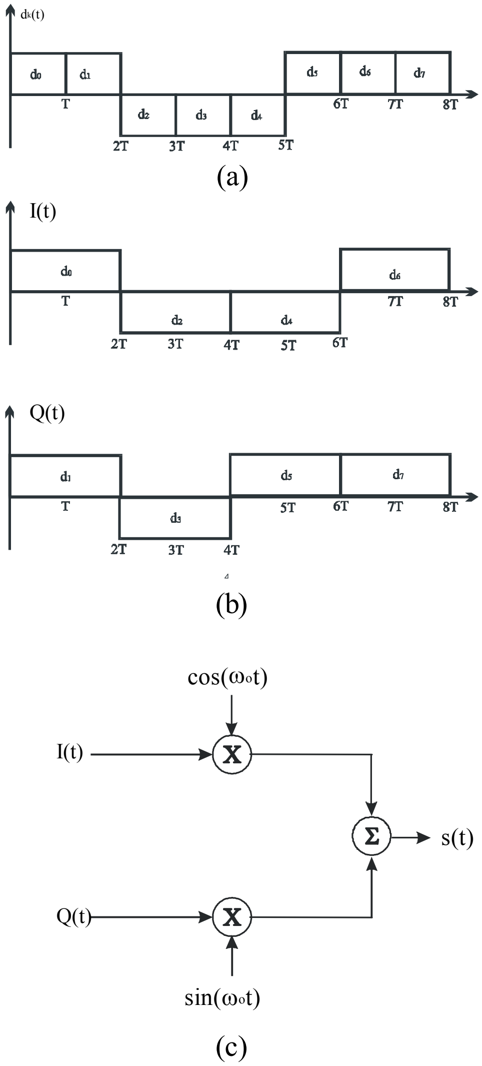

FIGURA 5
MODULAÇÃO EM FASE E QUADRATURA

Canal com Ruído Branco Aditivivo Gaussiano

Uma vez conhecida a lei de formação do sinal modulado, pode-se analisar a influência do ruído *AWGN* (*Aditive White Gaussian Noise*) [2] no sistema de comunicação. O ruído branco ou ruído térmico está sempre presente no canal de comunicação sendo um dos principais responsáveis pela causa de erros de recepção, se o mesmo não for bem analisado e dimensionado. O ruído branco pode ser modelado como uma variável aleatória (*VA.*) de média nula e variância σ^2 com distribuição Gaussiana. A média de uma *VA* representa o nível *DC* presente no sinal, enquanto que a variância representa a potência AC do sinal aleatório. Desta forma é possível determinar a relação sinal ruído através da potência do sinal desejado e da variância do sinal de ruído.

A Figura 6 mostra a constelação de um sistema *QPSK* transmitida através de um canal AWGN com relação sinal-ruído (*SNR*) de 4dB.

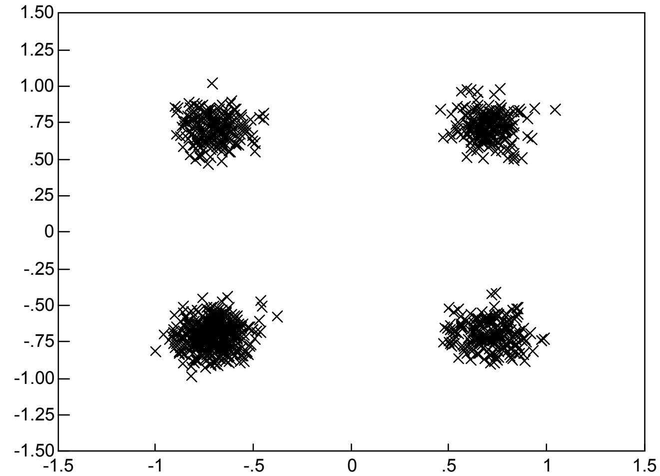

FIGURA 6
CONSTELAÇÃO QPSK

Canal com Desvanecimento Seletivo

Outro fator responsável pela degradação do desempenho dos sistemas digitais é a Interferência Intersimbólica (*ISI*) [3], introduzida por canais com múltiplos percursos. Esta interferência causa, no domínio da freqüência, nulos espectrais, denominado de desvanecimento seletivo. A resposta ao impulso de um canal com múltiplos percursos pode ser expressa por:

$$h(t) = A_0\delta(t) + A_1\delta(t-\tau_1) + ... + A_n\delta(t-\tau_n) \qquad (3)$$

Onde A_n e τ_n são a amplitude e o atraso de cada percurso, respectivamente.

Para um canal com apenas dois percursos, pode-se escrever a resposta impulsiva como:

$$h(t) = A_0\delta(t) + A_1\delta(t-\tau_1) \qquad (4)$$

A Resposta em Freqüência deste canal é obtida através da Transformada de Fourier de (4), conforme apresentado em (4).

$$H(j2\pi f) = \Im\{h(t)\} = A_0 + A_1 e^{j2\pi f\tau_1} \qquad (5)$$

A Figura 7 mostra a Resposta de Amplitude e Fase do canal modelado a partir de (4) e (5), com $A_0 = A_1 = 1$ e com τ_1=1s.

Pode-se perceber que a distâncias entre os nulos espectrais ocorrem a cada 1*Hz*, que representa o inverso do atraso sofrido pelo segundo canal. Deste modo pode-se definir a largura de faixa do canal, BW_{canal}, como sendo:

$$BW_{canal} = \frac{1}{\tau_1} \qquad (6)$$

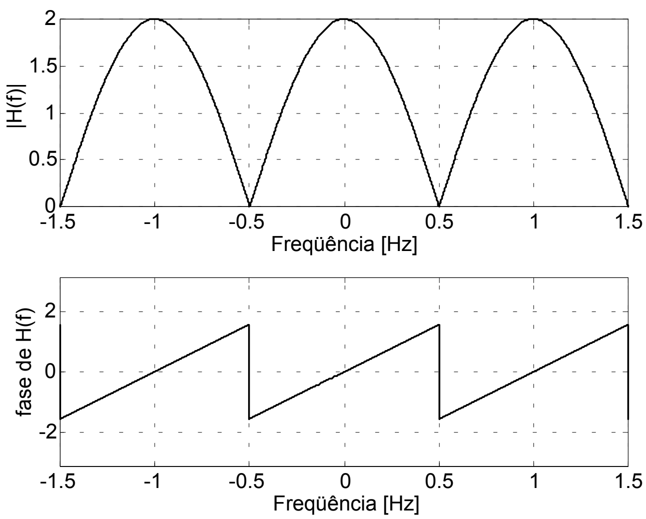

FIGURA 7
RESPOSTA EM FREQÜÊNCIA E EM FASE DO CANAL COM DESVANECIMENTO

A banda de coerência do canal, BW_c, é definida como a largura de faixa do canal no qual o mesmo pode ser considerado plano e pode ser expressada como:

$$BW_c = \frac{1}{5BW_{canal}} = \frac{1}{5BW_c} \qquad (7)$$

Deste modo, caso a largura de faixa do sinal a ser transmitido for menor do que a banda de coerência do canal, pode-se afirmar que o sinal sofre desvanecimento plano, ou seja, não ocorrem nulos espectrais dentro da faixa de interesse.

CONCLUSÕES

A necessidade de atualização e especialização exigida pelos alunos de Mestrado em Telecomunicações demanda a aprendizagem de um vasta gama de informações em um curto intervalo de tempo. Desta forma, se faz necessário utilizar abordagens diferentes técnicas de ensino para que este aprendizado se torne eficiente, como o uso de ferramentas computacionais e de laboratórios para simulações de sistemas de telecomunicações.

Este artigo apresentou duas experiências que facilitam o aprendizado de conceitos envolvidos em transmissão digital. A primeira experiência aborda a técnica de transmissão digital que utiliza espalhamento espectral. Nesta experiência, o aluno levanta o desempenho do sistema de comunicação *DS-SS* em canais que apresentam interferências intencionais de faixa larga ou faixa estreita, medindo o Ganho de Processamento efetivo do sistema. Já na segunda experiência, o aluno realiza um estudo sobre as modulações digitais em fase e quadratura, explorando a estrutura de geração de sinais digitais através de portadoras ortogonais. Realiza-se uma análise da influência do filtro cosseno elevado na modulação *QPSK*, bem como o desempenho do sistema em canais *AWGN* e com desvanecimento. Estas análises são realizadas tanto no domínio do tempo e da freqüência, além de apresentar o diagrama de constelação do sinal recebido.

Com isso, o aluno é capaz de corroborar os resultados apresentados na teoria com os dados obtidos nas medições práticas realizadas em laboratório, o que permite um aprendizado dinâmico e bem fundamentado.

VERIFICAÇÃO DE CONCEITOS SOBRE AMPLIFICADORES DE RÁDIO FREQUÊNCIA ATRAVÉS DO USO DO GENESYS/HARBEC 2003

Laert Calil Junior[1], Wilton Ney do Amaral Pereira[2], Maurício Silveira[3], Carlos Nazareth Mota Marins[4]

Resumo *- Este artigo mostrará a utilidade do programa GENESYS/HARBEC, desenvolvido pela empresa Eagleware, como facilitador no ensino da engenharia, para a descrição e análise de dispositivos não-lineares e de técnicas de linearização de amplificadores de potência em RF. Desta forma, é apresentado como resultado, o desempenho de um amplificador sem a utilização de técnicas de linearização e o desempenho deste mesmo amplificador utilizando algumas técnicas de linearização. Os objetivos do uso do GENESYS/HARBEC são: modelagem dos sinais no circuito usando um número finito de raias espectrais e verificação da estabilidade do circuito.*

Abstract *– This paper will show the utility of software GENESYS/HARBEC, developed for Eagleware company, to facilitate the education in engineering, to describe the performance analysis of non-linear devices and linearization techniques of RF amplifiers. In this way, it´s shown like as a result, the performance of a amplifier without use of linearization techniques and using some linearization tecniques. The targets to use the GENESYS/HARBEC are: modeling of sinals in the circuit using a finite number of harmonics spectra and checking the stability of circuit.*

INTRODUÇÃO

Em circuitos analógicos, é costume definir sistema linear, como aquele que tendo um espectro na entrada, o coloca na saída com um determinado ganho e algum atraso de fase, sem acrescentar ou retirar nenhuma componente a esse espectro. Na verdade, isso não acontece com nenhum tipo de circuito ativo. Apenas os elementos passivos e circuitos baseados nestes, se podem considerar lineares.

As não-linearidades introduzem componentes indesejáveis no sinal, ou retiram componentes do sinal desejado. Estes fenômenos se resumem na distorção harmônica, compressão do ganho e intermodulação.

Na tentativa de corrigir estas não-linearidades existem quatro técnicas principais de linearização de dispositivos não-lineares: alimentação no sentido direto *("feedforward")*; realimentação negativa *("feedback")*; pré-distorção; técnicas envolvendo processamento digital de sinais. Como o interesse é a análise de dispositivos não-lineares, o programa GENESYS/HARBEC foi utilizado porque é capaz de efetuar a simulação de equilíbrio harmônico destes dispositivos e das técnicas de linearização.

TÉCNICAS DE LINEARIZAÇÃO

Alimentação no sentido direto *("feedforward")*

Esta técnica foi desenvolvida pelo engenheiro eletrônico Harold S. Black. Inicialmente ignorada, ressurgiu quando métodos alternativos de linearização foram necessários para projetar amplificadores com grande retardo temporal, onde considerações de estabilidade excluíram o uso da realimentação negativa.

Nesta técnica, o sinal de entrada é dividido em duas partes por um divisor de potência, conforme indica a Fig. 1, onde o ramo superior dirige-se ao amplificador principal não-linear, geralmente em classe *AB* ou em classe *C*, e o outro ramo, para o elemento de retardo. Uma amostra do sinal distorcido na saída do amplificador principal é separada por meio de um acoplador direcional. Essa amostra é atenuada, e subtraída do sinal da entrada, via elemento de atraso L1. O sinal de erro resultante, idealmente contendo apenas distorção, é reforçado pelo amplificador de erro (em

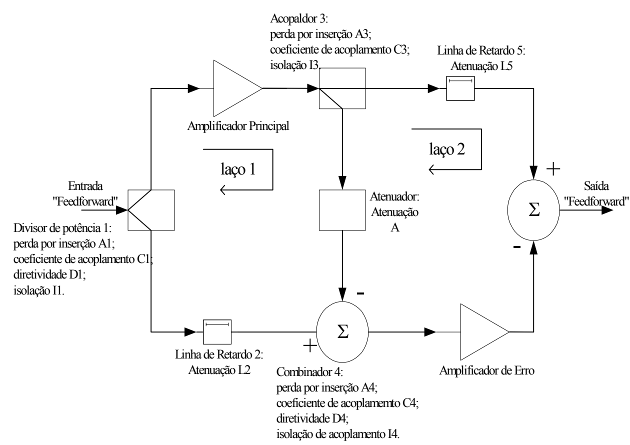

Figura 1 - Linearização por alimentação no sentido direto ("feedforward").

[4] Carlos Nazareth Mora Marins, INATEL, carlosn@inatel.br

classe A) antes de ser subtraído do sinal do amplificador principal com atraso devidamente ajustado, cancelando a distorção e entregando um sinal linearizado na saída.

Realimentação Negativa *("feedback")*

O modelo inicial deste tipo de sistema foi introduzido pelo engenheiro eletrônico Harold S. Black. A realimentação negativa permite trocar o ganho do modelo por alguma outra propriedade, como, por exemplo, a redução de distorção ou o aumento da largura de faixa.

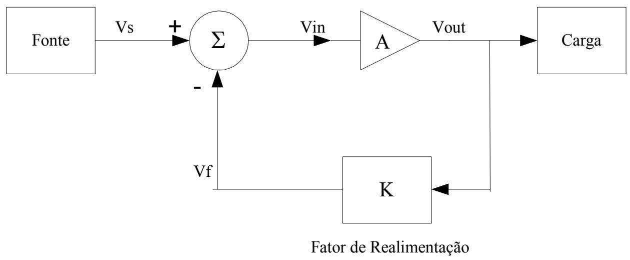

Figura 2 - Diagrama em blocos de um sistema realimentado.

A função de transferência do amplificador com realimentação é determinada por:

$$A_f = \frac{A}{1 + AK} \quad (1)$$

onde:
A: ganho do amplificador em malha aberta;
K: ganho do bloco de realimentação;
A_f : *ganho do sistema realimentado.*

Em geral, $A.K$ >>1, logo:

$$A_f = \frac{1}{K} \quad (2)$$

Nesta condição o ganho de um amplificador realimentado, A_f, é quase independente do ganho de malha aberta *A* e depende apenas da rede de realimentação.

A técnica de linearização por realimentação negativa se divide em quatro categorias: realimentação em RF, realimentação de envoltória, realimentação polar e realimentação cartesiana.

Pré-distorção

Este método cria uma distorção complementar à produzida pelo amplificador a ser linearizado. A saída de um amplificador não-linear pode ser representada pelo polinômio:

$$Vout = G_1 Vin(t) + G_2 Vin^2(t) + G_3 Vin^3(t) + ... + G_n Vin^n(t) \quad (3)$$

onde:
Vin: sinal de entrada;
Vout: sinal de saída;
$G_1, G_2, G_3, ..., G_n$: coeficientes do amplificador.

A distorção *AM-AM* e *AM-PM* introduzida pelo amplificador é função do nível do sinal de entrada e da contribuição dos coeficientes do amplificador. Se estes coeficientes são conhecidos (através de medidas e/ou simulações), a distorção do amplificador pode ser compensada pela introdução de uma característica que adicionada a não-linearidade permite um ganho linear do amplificador. A técnica de pré-distorção está dividida nas seguintes categorias: pré-distorção de RF; pré-distorção de FI; pré-distorção de banda básica.

Técnicas envolvendo processamento digital de sinais

Estas técnicas envolvem formas de processamento digital de sinais para alterar o sinal de entrada original em banda básica ou portadora modulada. Elas se baseiam na síntese da envoltória e fase de um sinal modulado em alta potência, com alta eficiência e usualmente não linear.

Todas as técnicas tem eficiência altas, se aproximando de 100% na maioria dos casos, o que as tornam atrativas e, consequentemente, muitas pesquisas tem sido direcionadas nesta área. Problemas práticos nas suas realizações e complexidade têm resultado em poucas aplicações comerciais até agora. Os principais métodos são: eliminação e restauração de envoltória (*EE&R*); amplificação linear usando componentes não-lineares (*LINC*); modulador universal analógico combinado de malha fechada (*CALLUM*); amplificação linear usando técnicas de amostragem (*LIST*).

SIMULAÇÃO

Introdução

Através do uso do programa GENESYS/HARBEC foi possível efetuar as simulações das seguintes técnicas: realimentação, pré-distorção e alimentação no sentido direto. As técnicas envolvendo processamento digital de sinais foram interpretadas como uma forma de pré-distorção.

Esta plataforma computacional possui um grande número de opções de componentes eletrônicos, passivos ou ativos, para vários tipos de simulações. Neste caso, para simular um amplificador não-linear, foi utilizado um componente que varia a tensão de saída conforme a tensão de entrada.

Para levantamento destes gráficos, foi utilizado um amplificador comercial com as seguintes características: ganho de potência: 20*dB*; ponto de compressão de 1dB: 8dBm; ponto de interceptação de 3*dB*: 18*dBm*. Após análise matemática foi possível determinar os coeficientes do polinômio apresentado como equação 3: $G1$ = 10; $G2$ = -5.83; $G3$ = -181,130656.

Os sinais aplicados no amplificador foram tons de 1,3 e 1,7MHz.

Os valores acima serão parte da função de transferência do dispositivo à ser utilizada na simulação.

Resultados

Utilizando os valores acima, os seguintes resultados foram obtidos para o dispositivo apresentado na Fig. 3, sem a utilização de técnicas de linearização.

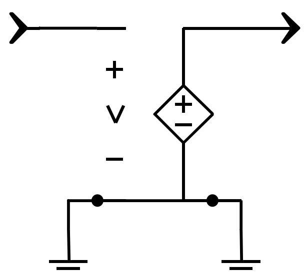

Figura 3 – Componente que simboliza o amplificador sem a utilização de técnicas de linearização.

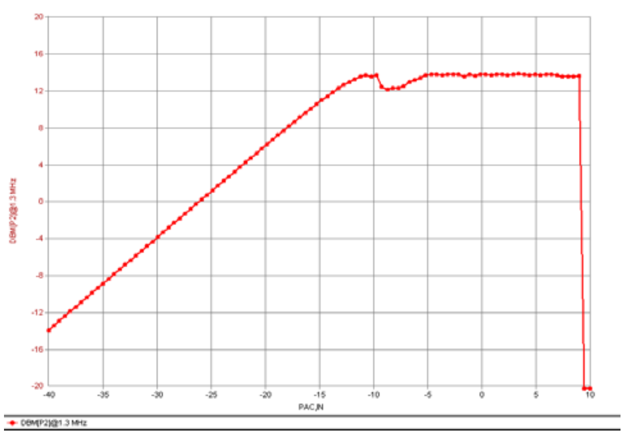

Figura 4 – Característica AM-AM.

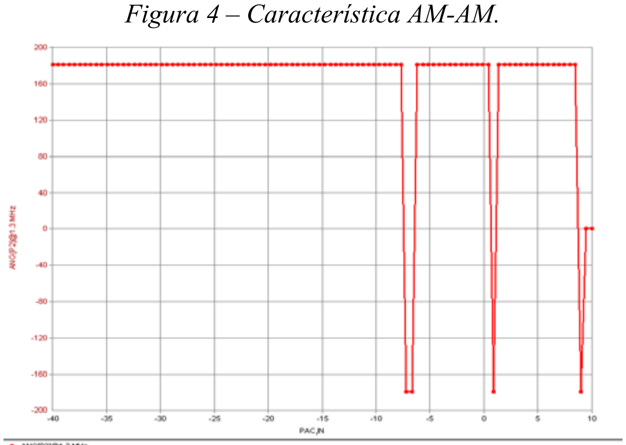

Figura 5 – Característica AM-PM.

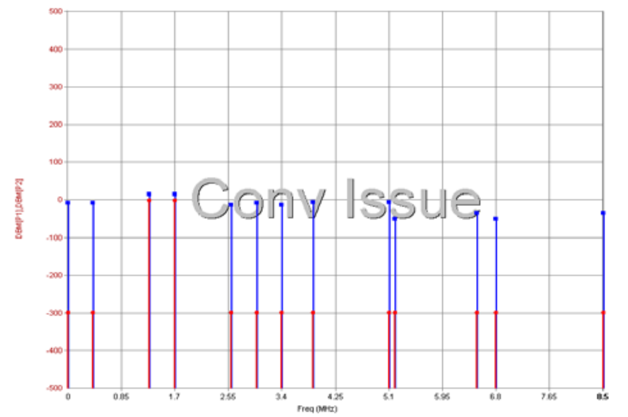

Figura 6 – Distorção de intermodulação.

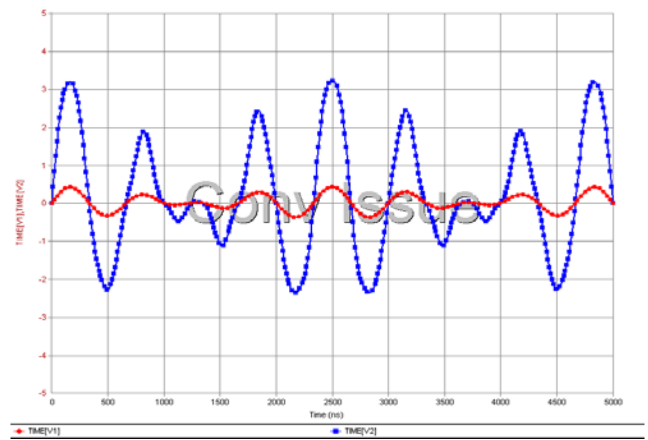

Figura 7 - Sinal de entrada e sinal de saída no domínio do tempo.

A Fig. 8 mostra o amplificador utilizando a técnica de realimentação onde foram obtidos os resultados mostrados nas Figs. 9, 10, 11 e 12 que representam as características *AM-AM*, *AM-PM*, distorção de intermodulação e sinais de tensão de entrada e saída no domínio do tempo, respectivamente:

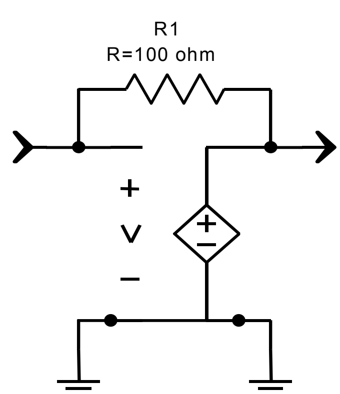

Figura 8 – Amplificador utilizando a técnica de linearização por realimentação.

Figura 14 – Característica AM-AM.

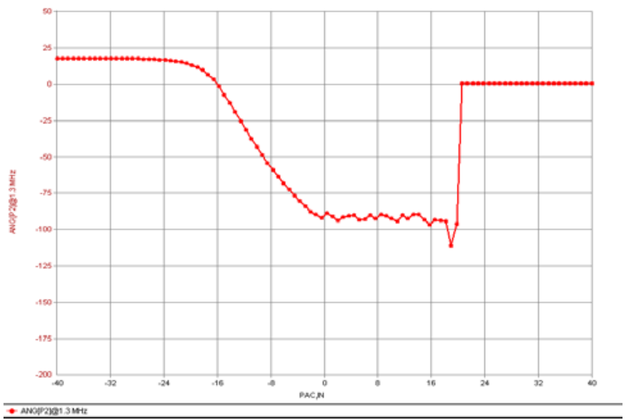

Figura 15 – Característica AM-PM.

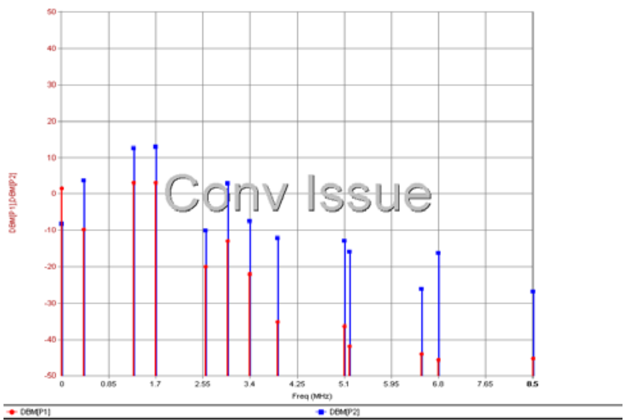

Figura 16 – Distorção de intermodulação.

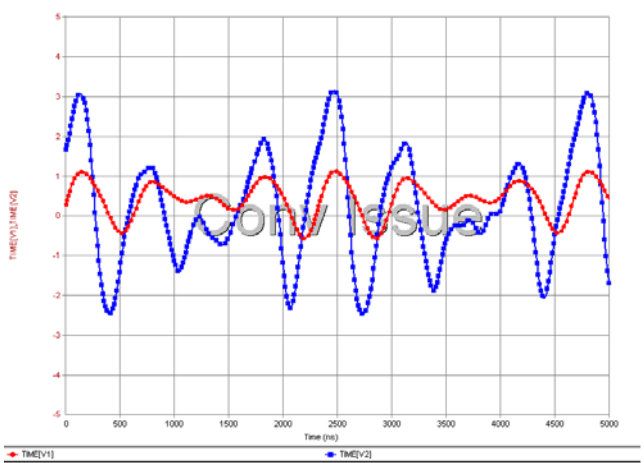

Figura 17 – Sinal de entrada e sinal de saída no domínio do tempo.

A Fig. 18 representa o amplificador utilizando a técnica de linearização por alimentação no sentido direto onde foram obtidos os seguintes resultados:

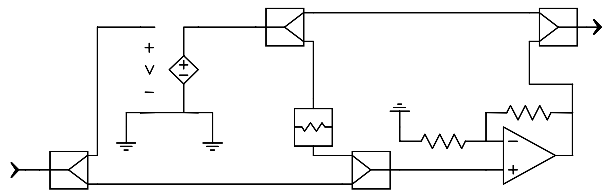

Figura 18 – Amplificador utilizando a técnica de linearização por alimentação no sentido direto.

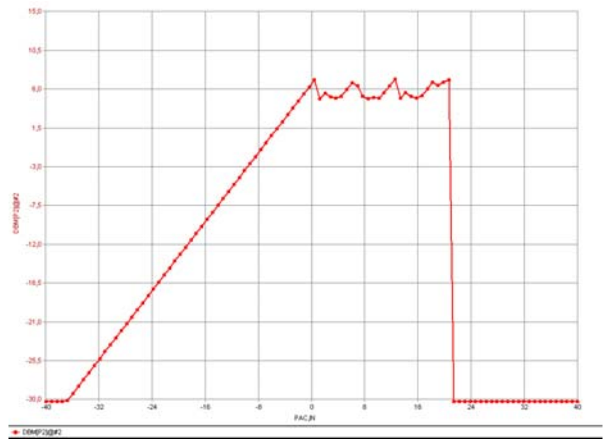

Figura 19 – Característica AM-AM.

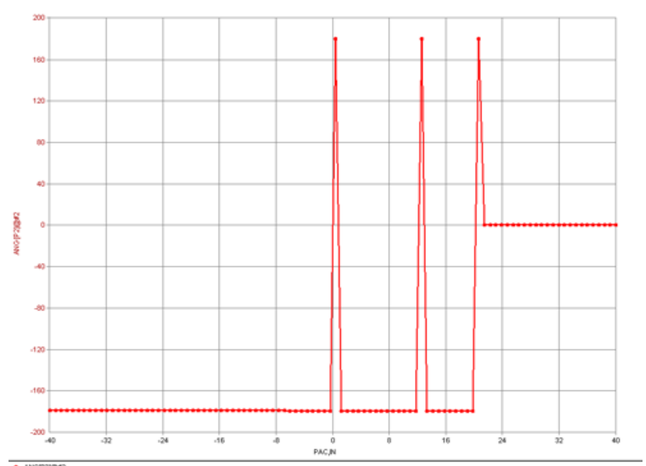

Figura 20 – Característica AM-PM.

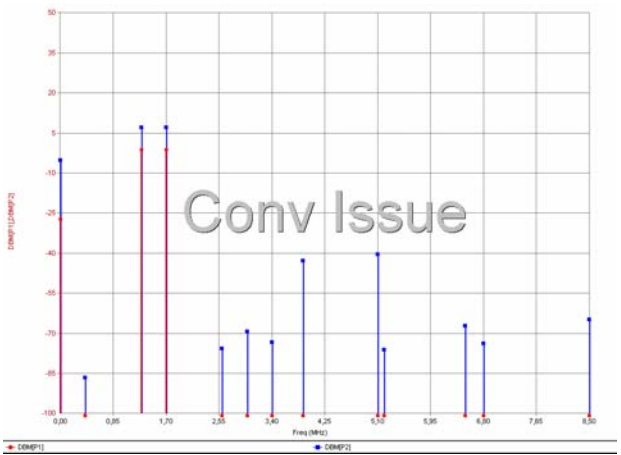

Figura 21 – Distorção de intermodulação.

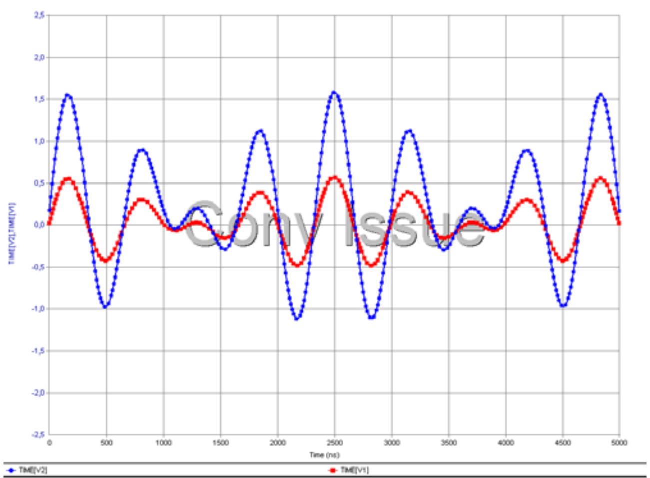

Figura 22 – Sinal de entrada e sinal de saída no domínio do tempo.

CONCLUSÃO

Devido a conceitos de dispositivos não-lineares, efeitos das não-linearidades e técnicas de linearização, foi possível observar que os resultados das simulações não foram totalmente satisfatórios.

Na simulação do amplificador sem a utilização de técnicas de linearização foram utilizados cem pontos para levantamento das características *AM-AM* e *AM-PM*. Foi possível observar deformidades na característica *AM-AM* e descontinuidades na característica *AM-PM*.

Na simulação do amplificador utilizando a técnica de linearização por realimentação as características *AM-AM* e *AM-PM* também foram simuladas com cem pontos. Nesta simulação não foi observada qualquer deformidade.

Na simulação do amplificador utilizando a técnica de linearização por pré-distorção a diodo em série as características *AM-AM* e *AM-PM* também foram simuladas com cem pontos. Nesta simulação foi observado deformidades na característica *AM-PM* e nos sinais de entrada e saída no domínio do tempo.

Na simulação do amplificador utilizando a técnica de linearização por alimentação no sentido direto foi observado deformidades na característica *AM-AM*, descontinuidade na característica *AM-PM.*

A versão do programa GENESYS/HARBEC utilizada nas simulações, não permitiu o total domínio dos resultados, provocando as situações mencionadas acima.

Fluxo de Carga versus Fluxo de Carga Continuado Parte I: Métodos Analíticos

Dilson A. Alves[1] *e Rogério R. Matarucco* [1]

Resumo — *O método de fluxo de carga convencional é considerado inadequado para se obter o ponto de máximo carregamento* (*PMC*) *de sistemas de potência, devido à singularidade da matriz Jacobiana neste ponto. Os métodos da continuação são ferramentas eficientes para a solução deste tipo de problema, visto que técnicas de parametrização podem ser utilizadas para evitar a singularidade da matriz Jacobiana. Neste trabalho são desenvolvidas as expressões analíticas que serão usadas para convalidar os resultados obtidos pelos métodos modificados de Newton e desacoplado rápido, existentes e propostos, considerando as variações de cargas numa única barra.*

Palavras - Chave — *Fluxo de Carga, métodos da continuação, ponto de máximo carregamento.*

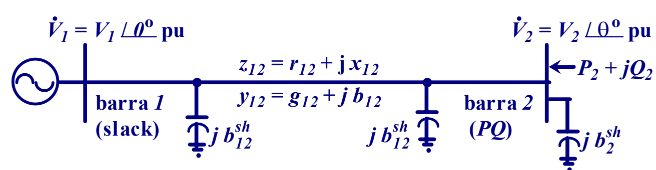
INTRODUÇÃO

A estabilidade de tensão tem se tornado uma questão crítica para a operação dos sistemas de potência. O crescimento contínuo da demanda associado às restrições econômicas e ambientais tem levado o sistema a operar próximo de seus limites. Portanto, o conhecimento preciso de quão distante o atual ponto de operação se encontra de seu limite de estabilidade é crucial para o operador. As análises estáticas de estabilidade de tensão de sistemas de potência podem ser realizadas através da obtenção do perfil de tensão das barras em função de seu carregamento (curvas PV, QV, e SV). Entre outras aplicações, estas curvas são utilizadas para se determinar os limites de transferência entre áreas de uma rede de transmissão, ajustes de margens, e comparação de planos de transmissão. Procedimentos automatizados de Fluxo de Carga (FC), utilizando o método convencional de Newton, foram adotados por muitas concessionárias para executar suas análises. Assim, estas curvas possibilitam a compreensão das condições de operação do sistemas para diferentes carregamentos. O uso dos métodos convencionais de FC para a obtenção das curvas está restrito à sua parte superior (correspondendo a operação estável). Para sistemas com cargas de potência constante, o aumento gradual de carga conduzirá ao PMC. Nestas condições, a matriz Jacobiana das equações do FC tornar-se-á singular. Consequentemente, o método convencional apresentará dificuldades numéricas. Estas ocorrerão mesmo quando do uso de cálculos com dupla-precisão e algoritmos anti-divergentes. Pontos de operação muito próximos ao PMC podem ser calculados utilizando métodos de FC convencional. Contudo, sempre será necessário ponderar se os problemas de não convergência são devidos aos problemas numéricos ou às limitações físicas do sistema. Em geral, as diferenças não são óbvias.

Os objetivos deste trabalho são os de introduzir os conceitos básicos dos métodos de Newton e desacoplado rápido propostos para a solução de fluxo de carga (FC) e demonstrar que, uma vez adequadamente equacionados, qualquer um deles pode ser usado para a obtenção do ponto de máximo carregamento (PMC) de um sistema de potência. Para alcançar tal objetivo, os métodos estão separados por grupos: analítico, de Newton, e desacoplado rápido, sendo os dois últimos apresentados respectivamente, nas partes II [1] e III [2] deste trabalho. Estes métodos, por sua vez, estão subdivididos de acordo com as curvas a serem traçadas: PV, QV, e SV. Ao final de cada grupo demonstra-se que os métodos utilizados no traçado das curvas PV e QV podem ser considerados como casos particulares do usado para o traçado da curva SV. Assim, primeiramente o traçado das curvas e os conceitos serão explicados a partir de equações analíticas obtidas para um sistema simples de duas barras. A seguir, as expressões analíticas são usadas para convalidar os resultados obtidos pelos métodos modificados de Newton e desacoplado rápido, existentes e propostos, considerando as variações de cargas numa única barra. Os métodos utilizados para o traçado das curvas PV, QV, e SV apresentados, podem, conforme será concluído na parte II [1], serem considerados como casos particulares do método da continuação usado para o traçado da curva SV, considerando variações de carga por todo o sistema.

Expressões Analíticas para um Sistema Simples

O objetivo da parte I é introduzir alguns conceitos básicos relacionados ao colapso de tensão utilizando, para isso, apenas expressões analíticas. Considere inicialmente um sistema simples de duas barras, interligadas por uma linha de



$$y_{12} = g_{12} + j\,b_{12} = \frac{r_{12}}{r_{12}^2 + x_{12}^2} + j\frac{-x_{12}}{r_{12}^2 + x_{12}^2} = y_{12}(cos\phi - jsen\phi)$$

onde $\phi = tg^{-1}\,(x_{12}/r_{12})$

FIGURA 1
SISTEMA DE DUAS BARRAS

[1] Dilson Amancio Alves e Rogério R. Matarucco, UNESP–Universidade Estadual Paulista, Departamento de Engenharia Elétrica, Câmpus de Ilha Solteira, C.P. 31, 15385-000, Ilha Solteira SP, Brasil, +55 18 3743 1163, dalves@dee.feis.unesp.br

© 2003 ICECE

transmissão (LT), como mostrado na Figura 1. Posteriormente, quando da apresentação dos métodos de Newton e desacoplado rápido, propriamente ditos, as expressões aqui desenvolvidas poderão ser utilizadas para se convalidar os resultados obtidos para o mesmo sistema. Observa-se que vários trabalhos propostos na literatura foram desenvolvidos a partir de um sistema simples como este [3]-[5].

As injeções de potência ativa (P_2) e reativa (Q_2) na barra *2* do sistema da Figura 1 são dadas por:

$$P_2 = Pg_2 - Pc_2 = G_2V_2^2 - V_2V_1\left(g_{12}\cos\theta_{21} + b_{12}\,sen\theta_{21}\right) \quad (1)$$

$$Q_2 = Qg_2 - Qc_2 = -B_2V_2^2 - V_2V_1\left(g_{12}\,sen\theta_{21} - b_{12}\cos\theta_{21}\right) \quad (2)$$

onde $G_2 = g_{12}$, $B_2 = (b_{12} + b_{12}^{sh} + b_2^{sh})$, $\theta_{21} = \theta_2 - \theta_1$, Pg_2 e Pc_2, Qg_2 e Qc_2, são as potências ativa e reativa geradas e consumidas, respectivamente, especificadas para a barra *2*. Adotando-se a barra *1* como referência angular ($\theta_1 = 0$), (1) e (2) podem ser colocadas nas seguintes formas:

$$P_2 - G_2V_2^2 = -V_2V_1\left(g_{12}\cos\theta_2 + b_{12}\,sen\theta_2\right) = -y_{12}V_2V_1\cos(\theta_2 + \phi) \quad (3)$$

$$Q_2 + B_2V_2^2 = -V_2V_1\left(g_{12}\,sen\theta_2 - b_{12}\cos\theta_2\right) = -y_{12}V_2V_1\,sen(\theta_2 + \phi) \quad (4)$$

Dividindo-se (3) pela (4) obtém-se:

$$\theta_2 = -\phi + tg^{-1}\left[\left(Q_2 + B_2V_2^2\right)/\left(P_2 - G_2V_2^2\right)\right] \quad (5)$$

Elevando ambos os lados de (4) e (5) ao quadrado, e somando-as a seguir, obtém-se:

$$\left(P_2 - G_2V_2^2\right)^2 + \left(Q_2 + B_2V_2^2\right)^2 = V_2^2V_1^2y_{12}^2, \quad (6)$$

de onde se pode obter o módulo da tensão na barra *2* da seguinte equação biquadrática em V_2:

$$\left(G_2^2 + B_2^2\right)V_2^4 - \left(2\left(G_2P_2 - B_2Q_2\right) + y_{12}^2V_1^2\right)V_2^2 + \left(P_2^2 + Q_2^2\right) = 0, \quad (7)$$

a qual apresentará solução real sempre que:

$$\Delta = \left(2\left(G_2P_2 - B_2Q_2\right) + y_{12}^2V_1^2\right)^2 - 4\left(G_2^2 + B_2^2\right)\left(P_2^2 + Q_2^2\right) \geq 0\,. \quad (8)$$

Sempre que os valores especificados para P_2, Q_2 e V_1 forem tais que a condição acima seja obedecida, o módulo da tensão na barra *2* será calculado por:

$$V_2^2 = \left[\left(2\left(G_2P_2 - B_2Q_2\right) + y_{12}^2V_1^2\right) \pm \sqrt{\Delta}\right] \Big/ 2\left(G_2^2 + B_2^2\right), \quad (9)$$

de onde se verifica que podem existir dois valores positivos para V_2. O valor obtido utilizando o sinal positivo em (9) corresponde à solução de alta tensão ou solução estável (V_2^H). Já, o valor obtido utilizando o sinal negativo corresponde à solução de baixa tensão ou solução instável (V_2^L). Para o sistema sem carga ($P_2 = Q_2 = 0$), e $B_2 = b_{12}$ (elementos *shunt* de barra e de linha desprezados), as soluções serão V_1 e zero, respectivamente. À medida que a carga da barra *2* aumentar, o valor de V_2^H diminuirá, enquanto o de V_2^L aumentará. Quando as duas soluções se igualarem (condição em que $\Delta = 0$ em (8)) ter-se-á atingido o PMC, ou ponto de máxima transferência de potência, ou potência crítica (P_{cr}). A tensão correspondente a este ponto é conhecida como tensão crítica (V_{cr}). A Figura 2 ilustra as grandezas P_{cr} e V_{cr} de forma genérica. Em particular, a curva mostra a variação da magnitude de tensão na barra *2* da rede da Figura 1 em função da variação de potência P_2.

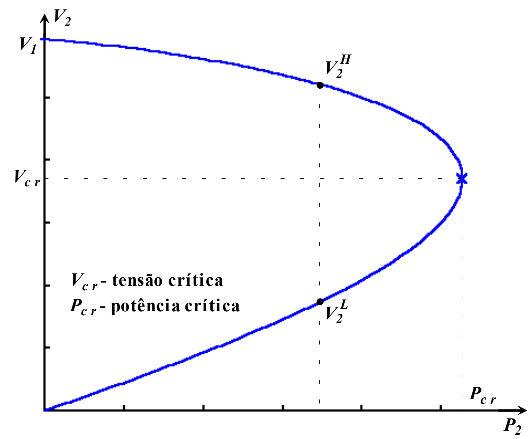


FIGURA 2
VARIAÇÃO DA MAGNITUDE DE TENSÃO V_2 EM FUNÇÃO DE P_2, COM $Q_2 = 0 =$ CONSTANTE, PARA A REDE DA FIGURA 1.

Equações Características da Curva PV

Considere um caso um pouco mais simples, para o qual os elementos *shunts* de linha e de barra são desprezados, ou seja, um caso em que $B_2 = b_{12}$. Obtêm-se os valores críticos para a potência ativa e a tensão (módulo e ângulo), colocando (8) e (9) nas seguintes formas:

$$\Delta = \left(V_1^2/2 + \left(r_{12}P_2 + x_{12}Q_2\right)\right)^2 - z_{12}^2\left(P_2^2 + Q_2^2\right) \geq 0\,, \quad (10)$$

$$V_2^2 = \left(V_1^2/2 + r_{12}P_2 + x_{12}Q_2\right) \pm \sqrt{\Delta}\,. \quad (11)$$

Considerando-se uma potência injetada ativa apenas ($P_2 = Pg_2 - Pc_2$ e $Q_2 = 0$), pode-se obter os valores máximos para as potências gerada (Pg_{2cr}) e consumida (Pc_{2cr}) fazendo o $\Delta = 0$ em (10), obtendo-se a seguinte equação:

$$P_{2cr}^2 - r_{12}/x_{12}^2\,V_1^2\,P_{2cr} - V_1^4/4x_{12}^2 = 0 \quad (12)$$

de onde tem-se:

$$Pg_{2cr} = V_1^2/2\left(z_{12} - r_{12}\right) \quad (13)$$

$$Pc_{2cr} = V_1^2/2\left(z_{12} + r_{12}\right) \quad (14)$$

A substituição de (13) e (14) em (11) fornece as seguintes tensões críticas:

$$Vg_{2cr} = \sqrt{z_{12}V_1^2/2\left(z_{12} - r_{12}\right)} = V_1/2\,sen(\phi/2) \quad (15)$$

$$Vc_{2cr} = \sqrt{z_{12}V_1^2/2\left(z_{12} + r_{12}\right)} = V_1/2\cos(\phi/2) \quad (16)$$

Nestas equações considerou-se apenas o sinal positivo da raiz por se tratar do módulo da tensão. O módulo da impedância da carga (z_c) no ponto crítico, é dada por V_{cr}^2 / P_{cr}. Com isso, fica fácil verificar, utilizando-se as quatro últimas equações, que a máxima transferência de potência ocorrerá quando o módulo da impedância da carga for igual ao módulo da impedância da linha. O ângulo crítico pode ser obtido de (5), colocando-a na seguinte forma:

$$tg(\theta_2 + \phi) = \left[\frac{-x_{12} / z_{12}^2}{P_2 / V_2^2 + r_{12} / z_{12}^2} \right] = \left[\frac{-x_{12}}{r_{12} \mu z_{12}} \right].$$

Como $P_2 = Pg_2 - Pc_2$, o sinal negativo para z_{12} no denominador corresponderá à carga, enquanto que o positivo à geração. O segundo termo da equação acima pode ser colocado ou na forma ($\sqrt{(1-\cos\phi)/(1+\cos\phi)} = tg(\phi/2)$), ou na forma ($-\sqrt{(1+\cos\phi)/(1-\cos\phi)} = cot\,g(-\phi/2)$), e assim os ângulos críticos são dados por:

$$\theta g_{2cr} = 90^{o} - \phi/2 \qquad (17)$$

$$\theta c_{2cr} = -\phi/2 \qquad (18)$$

As Equações (13) e (14) mostram que tanto a potência consumida quanto a gerada numa barra são limitadas, e em geral será possível gerar um pouco mais potência do que consumi-la. Por outro lado, como pode ser observado em (15) e (16), a tensão crítica para injeção de potência será maior do que a de consumo de potência. Uma característica desejada para um sistema é que a tensão crítica se mantenha a um nível, de preferência, o mais baixo quanto possível da tensão normal de operação, sem que isso, consequentemente, venha a prejudicar o perfil geral de tensão [6].

Uma forma de aumentar a máxima transferência de potência, é através da injeção de potência reativa. Para fornecer a compensação *shunt* necessária, pode-se utilizar de banco de capacitores ou compensadores estáticos. O uso de capacitores é atrativo do ponto de vista econômico, especialmente quando o suporte de reativos necessário é muito grande. A utilização de compensadores estáticos tem se tornado menos atrativa com o advento da tecnologia de chaveamento de alta velocidade (0,15 a 0,75 segundos) de bancos de capacitores controlados por tiristores, os quais podem ser operados por meio de relés de subtensão [6]-[7]. Entretanto, na Figura 3 pode-se observar uma característica indesejável do uso de compensação *shunt* por meio de capacitor. À medida que se aumenta a margem de estabilidade do sistema através do aumento da compensação, a tensão crítica se aproximará cada vez mais da faixa de operação normal do sistema (faixa sombreada: $0{,}9 \leq V \leq 1{,}1$p.u.), ou seja, o perfil de tensão tende a tornar-se cada vez mais plano. Consequentemente, o sistema fica mais propenso à ocorrência de colapso de tensão na faixa de operação normal. Dessa forma, em alguns casos, a despeito dos maiores custos iniciais e operacionais, o uso dos compensadores síncronos tem sido preferido ao invés de banco de capacitores *shunts* ou de compensadores estáticos, como por exemplo, no caso da Companhia Elétrica de Tóquio [6]. As razões desta escolha, conforme pode-se constatar na figura, são a de que estes além de não possuírem a característica de queda de potência reativa com o quadrado da tensão, possibilitam um aumento da margem de reativos com menores valores de tensão crítica.

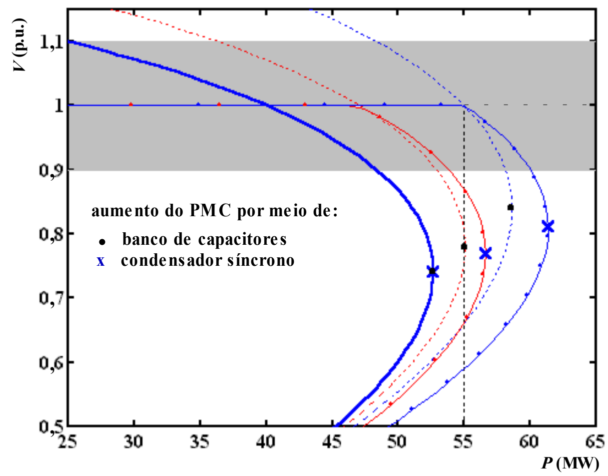

FIGURA 3
EFEITOS DA COMPENSAÇÃO DE REATIVOS SOBRE O PMC E A V_{CR}.

Uma outra observação refere-se ao valor da resistência (r_{12}) da LT. Como pode-se verificar das equações, à medida que r_{12} tender para zero, as máximas potências injetada e consumida tenderão para o mesmo valor $V_1^2/(2x_{12})$ (em módulo) e que é igual à metade da potência de curto-circuito da rede; os ângulos críticos tenderão para $\pm 45^o$, e as tensões tenderão para o mesmo valor $V_1/\sqrt{2}$.

Equações Características das Curvas QV e SV

Equações similares podem ser desenvolvidas para o caso em que $G_2 = g_{12} \neq 0$, $B_2 = b_{12}$ e $P_2 = 0$ (curva QV). Nestas condições as equações de (13) a (16) serão as mesmas bastando trocar r_{12} por x_{12}, observando somente que a última simplificação feita em (15) e (16) não é mais a mesma e sim:

$$Vg_{2cr} = \sqrt{z_{12} V_1^2 / 2(z_{12} - x_{12})} = V_1 / \sqrt{2(1 - sen\,\phi)}, \qquad (19)$$

$$Vc_{2cr} = \sqrt{z_{12} V_1^2 / 2(z_{12} + x_{12})} = V_1 / \sqrt{2(1 + sen\,\phi)}. \qquad (20)$$

Por outro lado, os ângulos críticos são dado por:

$$\theta g_{2cr} = -(90 + \phi)/2, \qquad (21)$$

$$\theta c_{2cr} = (90 - \phi)/2. \qquad (22)$$

Para o caso genérico de potência injetada na barra *2* (curva SV) considerando um ângulo de fator de potência qualquer (φ), a potência aparente crítica gerada (Sg_{2cr}) e consumida (Sc_{2cr}) são, respectivamente:

$$Sg_{2cr} = V_1^2 / 2\, z_{12} \left(1 - cos(\varphi - \phi)\right) \qquad (23)$$

$$Sc_{2cr} = V_1^2 / 2\, z_{12} \left(1 + cos(\varphi - \phi)\right) \qquad (24)$$

para o caso em que $G_2 = g_{12} \neq 0$, $B_2 = b_{12}$. As correspondentes tensões críticas serão dadas por:

$$Vg_{2cr} = \sqrt{V_1^2 / 2\left(1 - cos(\varphi - \phi)\right)} \qquad (25)$$

$$Vc_{2cr} = \sqrt{V_1^2 / 2\left(1 + cos(\varphi - \phi)\right)} \qquad (26)$$

Enquanto que os ângulos críticos são dados por:

$$\theta g_{2cr} = 90 + (\varphi - \phi)/2\,, \qquad (27)$$

$$\theta c_{2cr} = (\varphi - \phi)/2\,. \qquad (28)$$

Observe que estas equações estão na forma geral, e uma vez sendo válidas para qualquer fator de potência, as equações anteriores passam a ser uma particularidade destas.

Traçado das Curvas PV, QV e SV

O traçado da curva PV pode ser realizado através da seguinte equação:

$$P_2 = G_2 V_2^2 \pm \sqrt{V_2^2 V_1^2 y_{12}^2 - \left(Q_2 + B_2 V_2^2\right)^2} \qquad (29)$$

a qual foi obtida de (6). Dados os valores de Q_2 e V_1, para cada valor de V_2 obtém-se diretamente os valores de P_2. Da mesma forma que a equação para a tensão, esta equação mostra que há dois valores para P_2, e que ambos serão iguais quando $V_2^2 V_1^2 y_{12}^2 - \left(Q_2 + B_2 V_2^2\right)^2 = 0$.

Um outro aspecto importante sobre esta equação, quando comparada à (1), é que nesta P_2 é função apenas de V_2, enquanto que naquela é função também de θ_2, e que por sua vez, também variará com V_2. Portanto, dP_2/dV_2 obtida a partir de (29) será nula no ponto de máxima transferência de potência, enquanto que naquela, ou seja, na (1), ter-se-á apenas a derivada parcial de P_2 com relação a V_2, $\partial P_2/\partial V_2$, e que é obtida considerando-se θ_2 constante. Observa-se que $\partial P_2/\partial V_2$ será diferente de zero no ponto crítico, $\left(\partial P_2/\partial V_2\right)|_{V_{2cr},\theta_{2cr}} = V_1\, sen^2(\phi/2) / z_{12}\, cos(\phi/2) \neq 0$. Para o caso particular em que $B_2 = b_{12}$ e $Q_2 = 0$, ao se igualar dP_2/dV_2 a zero chega-se uma equação biquadrática em V_2, de onde se obtém (15) e (16).

O traçado da curva QV pode ser realizado através da seguinte equação:

$$Q_2 = -B_2 V_2^2 \pm \sqrt{V_2^2 V_1^2 y_{12}^2 - \left(P_2 - G_2 V_2^2\right)^2}\,, \qquad (30)$$

a qual também foi obtida de (6). Assim, uma vez conhecidos os valores de P_2 e V_1, pode-se obter diretamente o valor de Q_2 para cada valor atribuído a V_2. Comentários similares aos feitos para a (29) também podem ser feitos para esta equação.

Já a equação a seguir, também obtida a partir de (6), fornece a curva SV para o caso particular em que $G_2 = g_{12} \neq 0$, $B_2 = b_{12}$:

$$|S_2| = y_{12} V_2^2 \left(cos(\varphi - \phi) \pm \sqrt{(V_1/V_2)^2 - sen^2(\varphi - \phi)} \right), \quad (31)$$

para a qual, uma vez conhecidos os valores de V_1 e do ângulo do fator de potência φ, é possível traçar a curva SV variando-se o valor de V_2. Aqui também cabem comentários similares aos feitos com relação à (29). Outro fato importante agora, é que nesta equação se tem o módulo de S_2, devendo-se tomar o cuidado com relação ao sinal da função módulo:

$$|S_2| = S_2, \text{ se } S_2 = Sg_2 \qquad (32)$$

$$\text{e} \quad |S_2| = -S_2, \text{ se } S_2 = Sc_2. \qquad (33)$$

Estas equações possibilitam o traçado das curvas PV, QV e SV, de um sistema simples como o apresentado na Figura 1. Nas partes II [1] e III [2], as curvas PV, QV e SV completas serão primeiramente traçadas utilizando estas equações. A seguir, as curvas e as equações analíticas serão utilizadas para caracterizar as limitações dos métodos de cálculo de Fluxo de Carga existentes, métodos de Newton e desacoplado rápido, e as vantagens dos métodos propostos sobre estes.

Singularidade da Matriz Jacobiana

Conforme foi comentado na introdução, o uso dos métodos convencionais de FC para a obtenção das curvas PV,QV e SV, está restrito à sua parte superior (correspondendo a operação estável, ver Figura 2). Para sistemas com cargas de potência constante, o aumento gradual de carga conduzirá ao PMC. Afirma-se que nestas condições, a matriz Jacobiana das equações do FC tornar-se-á singular, isto é, o determinante da matriz será nulo. Uma conseqüência imediata desta singularidade é que o método de Newton convencional apresentará dificuldades numéricas mesmo quando do uso de cálculos com dupla-precisão e algoritmos anti-divergentes [8] e [9]. Por outro lado, nos métodos desacoplados, as matrizes utilizadas são calculadas, para a condição *flat-start* [2], a partir das respectivas submatrizes das matrizes Jacobianas dos métodos de Newton. Estas matrizes serão mal-condicionadas para o cálculo dos pontos das curvas (os quais, correspondem as soluções do FC) nas vizinhanças do PMC, bem como do próprio ponto. Este mal-condicionamento será responsável pela divergência do processo numérico de resolução do FC. Assim, as equações do FC não mais apresentam solução. Estas equações são essenciais para a análise estática da estabilidade de tensão, já que representam um limite para a região de operação estável. Quando as equações do FC não apresentam solução para uma dada condição de carregamento, conclui-se que a geração e a rede não são fisicamente capazes de suprir esta demanda, exigindo modificações ou no despacho da geração ou na topologia da rede de transmissão, ou em ambas, para que tal demanda possa ser atendida com segurança [10].

Cabe observar entretanto, que a singularidade da matriz J do método de Newton no PMC, é devida à redução do *rank* da matriz J, não significa que neste ponto (PMC) o sistema não tenha solução. Na realidade ela existe, é única, e bem definida. Portanto, para se obter a solução, é necessário acrescentar a informação perdida com a redução do *rank*, ou modificar a matriz de forma a eliminar a singularidade [11]. Para carregamentos maiores que o do PMC, no entanto, as equações de FC não têm solução. Pontos de operação muito próximos ao PMC podem ser calculados utilizando métodos de FC convencional [12]. Contudo, sempre será necessário ponderar se os problemas de não convergência são devidos aos problemas numéricos ou às limitações físicas do sistema. Em geral, as diferenças não são óbvias.

O objetivo agora é o de demonstrar que a matriz Jacobiana é singular (apresenta determinante nulo) no PMC. Para isso, considere as equações linearizadas do FC, que de acordo com o método de Newton-Raphson, são dadas por:

$$\left[\frac{\Delta P}{\Delta Q}\right] = \left[\begin{array}{c|c} H & N \\ \hline M & L \end{array}\right]\left[\frac{\Delta\theta}{\Delta V}\right] = J\left[\frac{\Delta\theta}{\Delta V}\right] \qquad (34)$$

onde J é a matriz Jacobina e H, N, M e L são submatrizes que correspondem às derivadas de potência com relação às tensões e aos seus ângulos. ΔP e ΔQ correspondem aos *mismatches* de potências ativas e reativas, respectivamente, enquanto ΔV e $\Delta\theta$ correspondem às correções das magnitudes e ângulos das tensões. Isto pode ser demonstrado para as condições estabelecidas pelas equações analíticas de (13) a (18). Para o caso do exemplo da Figura 1, J será dada por:

$$\left[\begin{array}{c|c} \partial P_2/\partial\theta_2 & \partial P_2/\partial V_2 \\ \hline \partial Q_2/\partial\theta_2 & \partial Q_2/\partial V_2 \end{array}\right], \qquad (35)$$

cujo determinante, após obter-se as derivadas parciais de (3) e (4), e substituí-las em (2), é dado por:

$$det|J| = [-y_{12}V_1V_2\,sen(\theta_2+\phi)][y_{12}V_1\,sen(\theta_2+\phi)+2b_{12}V_2] - [y_{12}V_1V_2\,cos(\theta_2+\phi)][y_{12}V_1\,cos(\theta_2+\phi)-2g_{12}V_2],$$

a qual pode ser simplificada para a forma:

$$det|J| = 2y_{12}^2V_1V_2(V_2\cos\theta_2 - V_1/2), \qquad (36)$$

Agora, utilizando-se as equações, (15) e (17) no caso de geração de potência, ou (16) e (18) no caso de consumo, comprova-se que o termo entre parênteses se anula, e, portanto, o $det\,|J|$ também será nulo no PMC. Na parte II [1] será demonstrado como se eliminar a singularidade da matriz J e possibilitar o cálculo do PMC sem qualquer problema numérico.

CONCLUSÕES

Neste trabalho foram desenvolvidas, para um sistema de 2 barras, as expressões analíticas que serão usadas para convalidar os resultados obtidos pelos métodos modificados de Newton e desacoplado rápido, existentes e propostos, considerando as variações de cargas numa única barra. Estas expressões possibilitam, para o sistema de duas barras em particular, o traçado completo das curvas PV, QV e SV, bem como a determinação de seus respectivos valores críticos (V_{cr}, θ_{cr} e P_{cr}, Q_{cr} ou S_{cr}). O traçado destas curvas pode ser realizado a partir do conhecimento do valor de V_1 e do valor de Q_2, P_2 ou do ângulo do fator de potência φ, respectivamente, por simples variação da tensão V_2 no terminal da carga.

Fluxo de Carga versus Fluxo de Carga Continuado Parte II: Métodos de Newton

Dilson A. Alves[1] e Rogério R. Matarucco [1]

Resumo — *O método de fluxo de carga convencional é considerado inadequado para se obter o ponto de máximo carregamento (PMC) de sistemas de potência, devido à singularidade da matriz Jacobiana neste ponto. Os métodos da continuação são ferramentas eficientes para a solução deste tipo de problema, visto que técnicas de parametrização podem ser utilizadas para evitar a singularidade da matriz Jacobiana. Neste trabalho são apresentados e avaliados os métodos de Newton convencional e propostos, considerando as variações de cargas numa única barra.*

Palavras - Chave — Fluxo de Carga, métodos da continuação, ponto de máximo carregamento.

INTRODUÇÃO

Os objetivos deste trabalho são os de introduzir os conceitos básicos dos métodos de Newton propostos para a solução de fluxo de carga (FC) e demonstrar que, uma vez adequadamente equacionados, a nova matriz Jacobiana não mais será singular no PMC. Assim, qualquer um dos métodos propostos poderá ser usado para a obtenção do PMC de um sistema de potência. Os métodos estão subdivididos de acordo com as curvas a serem traçadas: PV, QV, e SV. Ao final demonstra-se que os métodos utilizados no traçado das curvas PV e QV podem ser considerados como casos particulares do usado para o traçado da curva SV. As expressões analíticas apresentadas na parte I [1] são usadas para convalidar os resultados obtidos pelos métodos modificados de Newton, existente e propostos, considerando as variações de cargas numa única barra. Finalmente, conclui-se que todos os métodos aqui apresentados são casos particulares do método da continuação, e que utilizam, no passo preditor, a técnica de previsão trivial conhecida como polinomial modificada de ordem zero, a qual usa a solução atual e um incremento fixo no parâmetro escolhido, como uma estimativa para a próxima solução.

OBTENÇÃO DAS CURVAS QV, PV E SV PELO MÉTODO DE NEWTON [2]-[4]

A seguir apresentam-se os métodos de Newton-Raphson utilizados para o traçado das curvas QV, PV, e SV, para o caso de variação de potência em apenas uma única barra. O entendimento destes métodos aplicados a um sistema simples facilita a análise de casos mais gerais e mais próximos da realidade, nos quais a potência é variada ao longo de todo o sistema.

Curva QV

As curvas QV expressam a relação entre o suporte de reativos (Q_r) numa dada barra e a tensão naquela barra [4]. Trata-se de um método clássico de análise estática da estabilidade de tensão, no qual uma fonte fictícia de potência ativa nula e de potência reativa variável (por esta razão denominada como compensador síncrono, sem limite de reativos), é colocada numa barra especificada (para a qual se deseja obter a máxima potência reativa ou a margem de reativo) e a tensão é variada para obter a curva QV. Nos termos de FC, a barra é simplesmente redefinida como barra tipo *PV*, sendo uma de suas principais vantagens pois é de fácil implementação. Dessa forma, para cada tensão especificada executa-se um programa de FC e obtém-se a potência reativa necessária para se manter o nível preestabelecido de tensão. A redefinição da barra se faz necessária para a eliminação da singularidade da matriz *J*, que como foi visto se torna singular no PMC. Com a especificação da tensão V_k eliminam-se a linha e a coluna *k* da matriz *J* correspondente a $\partial Q_k/\partial V_k$; procedimento similar ao utilizado ao se adotar uma determinada barra como referência angular para eliminar a singularidade de *J*, no FC convencional. Por fazer uso do FC esse método permite levar em conta as não linearidades relacionadas aos limites de geradores e de *tap* de transformadores, bem como a dependência da carga com relação à tensão. Outra vantagem do uso da curva QV é que as características de compensadores *shunts* de potência reativa (capacitores, e compensadores estáticos ou síncronos) podem ser representadas no mesmo gráfico, sendo o ponto de operação a interseção das duas curvas. O procedimento utilizado para se obter a curva QV é o seguinte [5]:

- Execute um FC para a condição de operação desejada (geralmente a condição se refere a uma situação de pós – contingência). Observa-se que a não convergência do FC para o caso base pode ser devida ao déficit de potência reativa. Neste caso o procedimento mais apropriado seria ir para o passo seguinte. O montante de potência reativa fornecido pelo compensador após a convergência corresponderá ao déficit de reativos.
- Após a escolha da barra para a qual se deseja obter a curva, conecte um compensador síncrono com potência ativa nula.
- Varie a tensão especificada para o compensador (usualmente são utilizados passos de 0,01 p.u. ou menos) e resolva o FC. Registre os valores da tensão (*V*) e da potência reativa (*Q*) do compensador.

[1] Dilson Amancio Alves e Rogério R. Matarucco, UNESP–Universidade Estadual Paulista, Departamento de Engenharia Elétrica, Campus de Ilha Solteira, C.P. 31, 15385-000, Ilha Solteira SP, Brasil, +55 18 3743 1163, dalves@dee.feis.unesp.br

- Repita os passos de 3 a 4 até obter um número suficiente de pontos, e, a seguir, plote a curva QV.

Uma outra forma de se obter as curvas QV, seria através da especificação do ângulo (θ_k) da barra k ao invés da tensão (V_k). Às vezes essa opção pode ser útil como se verá posteriormente. Com a especificação do ângulo θ_k eliminam-se a linha e a coluna k da matriz J correspondente à $\partial Q_k/\partial\theta_k$; a barra é redefinida como sendo do tipo $P\theta$ e não mais PV. Para que isso seja possível, o sistema matricial (35) da parte I [1] que corresponde ao sistema da Figura 1, deve ser colocado na seguinte forma:

$$\begin{bmatrix}\Delta Q_2\\ \Delta P_2\end{bmatrix}=\begin{bmatrix}\partial Q_2/\partial\theta_2 & \partial Q_2/\partial V_2\\ \partial P_2/\partial\theta_2 & \partial P_2/\partial V_2\end{bmatrix}\begin{bmatrix}\Delta\theta_2\\ \Delta V_2\end{bmatrix}, \qquad (1)$$

onde, após a eliminação da linha e da coluna correspondente à $\partial Q_2/\partial\theta_2$, para cada valor fixado de θ_2 obtém-se o respectivo valor de Q_2. Neste caso não mais ocorrerão problemas numéricos posto que a matriz Jacobiana de (1) não é singular no ponto crítico, uma vez que nesse ponto $\partial P_2/\partial V_2 \neq 0$, conforme os comentários referentes à (29) parte I [1]. Observa-se que embora o parâmetro seja a variável θ_2, pode-se traçar a curva QV com as tensões (V_2) e potências reativas (Q_2) obtidas para cada valor de θ_2 especificado. Esta curva será exatamente a mesma curva obtida pela especificação de V_2. É bom relembrar aqui que num FC convencional, para uma barra k qualquer, existem a princípio quatro variáveis: P_k, Q_k, V_k e θ_k. Quando a barra é uma barra de carga as potências P_k e Q_k são conhecidas *a priori* e, portanto, são especificadas e tratadas como variáveis independentes, deixando as outras duas como variáveis dependentes. Como no caso se procura a máxima potência reativa $Q_{máx}$ numa barra em que P_k é mantida constante, ou seja, se deseja obter a margem de potência reativa ainda disponível, P_k deverá ser especificada enquanto Q_k deverá ser tratada como variável dependente. Assim restam ainda as duas outras variáveis, V_k e θ_k, a serem definidas como variável dependente ou independente. Em função do número de equações possíveis para cada barra ser igual a *2*, deve-se especificar ainda mais uma variável. Assim, pode-se definir tanto V_k quanto θ_k como variável dependente.

Uma observação com relação às curvas é quanto à terminologia usada, por exemplo, no caso da curva QV que usa Q como variável dependente (eixo das ordenadas) e V como variável independente (eixo das abscissas), e que portanto deveria ser denominada por curva VQ ao invés de QV. Por outro lado, apesar de haver uma convergência na literatura para o uso da terminologia QV, neste trabalho é adotada uma ou outra terminologia conforme a conveniência. No caso do uso de θ como variável independente a curva deveria ser denominada por θQ, entretanto, como se verá mais a frente, o objetivo da mudança de variável (V para θ) é para possibilitar o traçado da curva QV e não θQ. Sendo assim, embora se use θ como variável independente, o que se obtém é a curva QV.

Curva PV

A curva PV é a curva de máxima transferência de potência como função da tensão para um dado fator de potência. A relação entre as curvas PV e QV indica que a curva PV é a linha sobre a qual não existe, por todo o sistema, desequilíbrios de potência reativa. As curvas QV devem ser obtidas para cada nível de carga de interesse para encontrar a margem de MW ou MVAr, ou seja, as curvas QV são calculadas ao longo da curva PV testando a robustez do sistema para vários níveis de carregamento. Além disso, as curvas PV são úteis para análises conceituais de estabilidade de tensão e para estudo de sistemas radiais, sendo usadas também, para sistemas malhados onde P representa a carga total do sistema ou a potência de intercâmbio. O benefício desta metodologia de análise é que esta provê uma indicação da proximidade do colapso ao longo de toda uma faixa de variação de carga, para a rede em análise.

Uma das formas de se obter a curva PV é através do uso de um FC convencional, o qual será executado para cada P especificado. Entretanto, como foi visto, este procedimento tem por inconveniência o fato de não eliminar a singularidade da matriz J. As curvas PV fornecem a variação (sensibilidade) da tensão da barra (ou de outras variáveis) com relação à carga, a margem de estabilidade de tensão, e a tensão para a qual a instabilidade ocorre. Ao invés de se usar um FC convencional pode-se conseguir uma boa estabilidade numérica com pequenas mudanças, similares às feitas para a obtenção da curva QV. Pode-se especificar tanto o ângulo θ_k quanto a tensão V_k. No primeiro caso elimina-se a linha e a coluna k correspondente à $\partial P_k/\partial\theta_k$ (o que é feito simplesmente colocando-se um número muito grande na diagonal); a barra é redefinida como sendo do tipo $Q\theta$. No segundo caso elimina-se a linha e a coluna k correspondente à $\partial P_k/\partial V_k$; a barra é redefinida como sendo do tipo QV. Para que isso seja possível, o sistema matricial (35) da parte I [1] e que corresponde ao sistema da Figura 1 p. ex., deve ser colocado na seguinte forma:

$$\begin{bmatrix}\Delta Q_2\\ \Delta P_2\end{bmatrix}=\begin{bmatrix}\partial Q_2/\partial\theta_2 & \partial Q_2/\partial V_2\\ \partial P_2/\partial\theta_2 & \partial P_2/\partial V_2\end{bmatrix}\begin{bmatrix}\Delta\theta_2\\ \Delta V_2\end{bmatrix}, \qquad (2)$$

onde, após a eliminação da linha e da coluna correspondente à $\partial P_2/\partial V_2$, para cada valor fixado de V_2 obtém-se o respectivo valor de P_2. Neste caso não mais ocorrerão problemas numéricos posto que a singularidade foi removida, uma vez que no ponto crítico $\partial Q_2/\partial\theta_2 \neq 0$ $\left((\partial Q_2/\partial\theta_2)|_{V_{2cr},\theta_{2cr}} = y_{12}V_1^2 \neq 0\right)$. No que se refere à terminologia adotada para a curva PV, valem os mesmos comentários feitos para as curvas QV.

Exemplos Ilustrativos

Para ilustrar os métodos de traçado das curvas QV e PV apresentados até aqui considere o sistema da Figura 1, apresentada em [1], para o qual foram adotados os seguintes valores $\dot{V}_1 = 1{,}19\underline{/0^o}$ p.u. (barra *slack*), z_{12} = 0,3 + j 1,0 p.u., e $b_{12}^{sh} = b_2^{sh} = 0$. Os objetivos das figuras apresentadas a seguir são o de convalidar os resultados obtidos com o traçado das curvas com as equações desenvolvidas na parte I [1], e o de comparar os desempenhos dos métodos modificados e o convencional.

Fluxo de Carga Convencional

A Figura 1 a seguir apresenta as curvas PV obtidas pelo método convencional considerando apenas variações de potência ativa na barra *2*. A curva foi obtida através de incrementos sucessivos de potência ativa na barra *2*. Os dois casos considerados, aumento de geração e de carga, foram plotados na mesma por conveniência, já que pela convenção utilizada as potências apresentam sinais opostos. Inicialmente os incrementos foram de 5 MW, para cada um dos quais foi resolvido um FC, sendo que o número de iterações gasta em cada um foi de 2 (o limite máximo de iterações adotado foi de 10). Para o primeiro ponto em que o FC divergiu foi feita uma redução de passo de 1/10, retornou-se ao passo anterior e aplicou-se o novo incremento, o qual passou a ser de 0,5 MW. O mesmo procedimento foi usado para o ponto de divergência subseqüente, enquanto que no seguinte o procedimento foi finalizado. Como pode-se ver nos detalhes da Figura 1, o PMC, ponto A ou B, não foi alcançado. Os valores exatos para a máxima potência (95,164 e 5,681 MW) e tensão crítica (0,997 e 0,742 p.u.) podem ser obtidos das respectivas equações da parte I [1], (13) e (14) para Pg_{cr} e Pc_{cr}, e (15) e (16) para Vg_{cr} e Vc_{cr}.

Singularidade da Matriz Jacobiana (*J*)

Conforme já mencionado, o método convencional começa a apresentar problemas numéricos na vizinhança de PMC, pois neste ponto a matriz *J* torna-se singular. As Figuras 2(a) e(b) apresentam os valores do determinante de *J* juntamente com os determinantes de outras matrizes que são apresentadas a seguir. Ambas as figuras foram obtidas especificando-se vários valores para a tensão da barra *2*, ou seja, redefinindo o tipo da barra como *QV* e *PV*, respectivamente. Foram realizadas 2 iterações por ponto da curva, considerando passo de 0,01 p.u. na tensão, observando-se ainda que o FC para a obtenção de um novo ponto da curva é iniciado a partir do FC convergido para o ponto anterior. Os objetivos destas figuras são ilustrar o método de identificação da barra crítica apresentado em [6], e confirmar a singularidade da matriz (*J*) no PMC (ponto A na Figura 2(a), e A' na Figura 2(b)). Nas figuras é mostrado também o determinante da matriz Jacobiana modificada (J_m), utilizando a tensão na barra *2* como parâmetro. Nota-se que J_m não é singular em A e A' quando do uso das modificações anteriormente sugeridas.

A metodologia proposta em [6] é baseada no uso da fórmula de *Schur* para determinantes. Assume-se uma variação incremental de geração ou de carga ΔP_i e ΔQ_i numa barra *i* de um sistema, enquanto que todas as demais injeções nodais de potência permanecem constantes. Nestas condições o sistema linearizado das equações do sistema será:

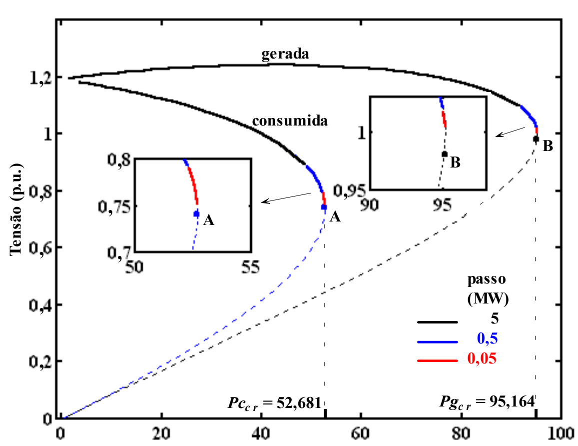

FIGURA 1
CURVAS PV UTILIZANDO FC CONVENCIONAL.

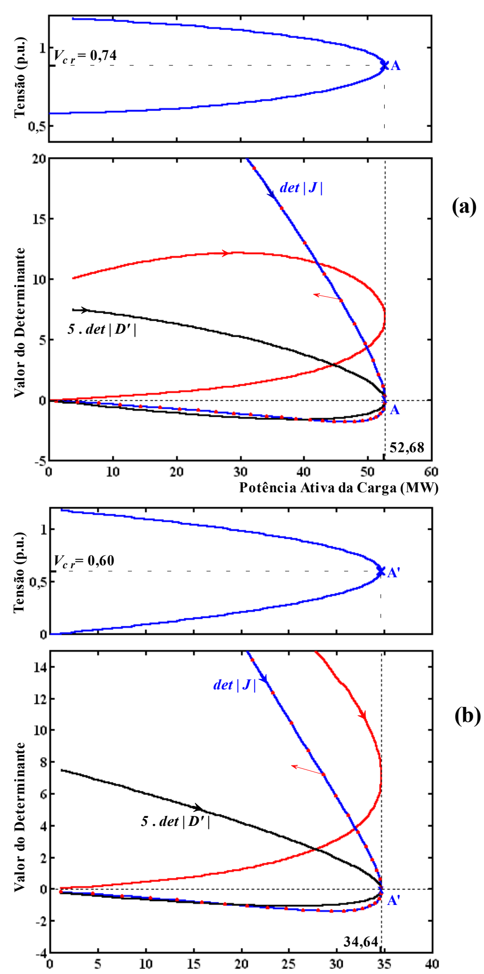

FIGURA 2
SINGULARIDADE DAS MATRIZES.

$$\left[0 \quad 0 \mid \Delta P_i \quad \Delta Q_i\right]^T = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right]\left[\Delta\theta \quad \Delta V \mid \Delta\theta_i \quad \Delta V_i\right]^T , (3)$$

sendo que as submatrizes $A_{(2nb\text{-}2\text{-}npv)\ \times\ (2nb\text{-}2\text{-}npv)}$, $B_{(2nb\text{-}2\text{-}npv)\ \times\ 2}$, $C_{2\ \times\ (2nb\text{-}2\text{-}npv)}$, e $D_{2\ \times\ 2}$ são partições da matriz *J*, e *nb* e *npv* são respectivamente o número de barras do sistema e de barras *PV*. De acordo com a fórmula de *Schur*: $det| J | = det| A | \times det| D - C A^{-1} B | = det| A | \times det| D' |$. Uma vez que a matriz *A* é não singular, a singularidade da matriz *D'* implica na singularidade da matriz *J*. O sinal e a magnitude de *det*| *D'* | traduzem a sensibilidade do módulo e do ângulo da tensão em relação à variação de carga ativa e reativa na barra em análise. Se o *det*| *D'* | > 0, o sistema encontra-se na região normal de operação, região estável. Se o *det*| *D'* | < 0, o sistema encontra-se na região anormal de operação onde as ações de controle podem ter efeito oposto ao esperado, para o caso de cargas de potência constante. A barra associada ao menor *det*| *D'* | é considerada a barra crítica. Observa-se que a determinação da barra crítica por esta metodologia requer o cálculo de *D'* para todas as barras, o que implica num elevado consumo de tempo no caso de grandes sistemas. A vantagem de se usar o *det*| *D'* | ao invés do *det*| *J* | é que este último, em geral, apresenta valores muito elevados (da ordem de 5 vezes maior no caso de um sistema pequeno como este - comparar os valores de ambos nas figuras), enquanto que o primeiro não. Também, a mudança de sinal do *det*| *J* | ocorre de forma muito brusca, o que praticamente inviabiliza o seu uso nas análises de colapso de tensão. As Figuras 5(a) e 5(b) mostram também *det*| *D'* | e *det*| *A* | × *det*| *D'* |. Estes são nulos no PMC (pontos A e A').

Métodos Modificados

A Figura 3 apresenta o uso dos métodos modificados para a obtenção das mesmas curvas apresentadas na Figura 1, onde agora incluiu-se também, as correspondentes curvas de variação do ângulo da barra *2*. Os passos utilizados para a obtenção dos pontos da curva foram de 5,0 MW para o método convencional, 0,01 p.u. para os modificados parametrizados por tensão, e 2 graus para o parametrizado por ângulo. Os valores de potência máxima e tensão crítica podem ser comparados aos fornecidos quando dos comentários feitos para a Figura 1. Já os valores exatos dos respectivos ângulos críticos θg_{cr} = 53,35º e θc_{cr} = –36,65º, podem ser obtidos de (17) e (18) da parte I [1], respectivamente. Nestas curvas pode-se observar algumas características importantes dos diversos métodos. Como já comentado na Figura 1, o método convencional diverge no ponto C, sendo que para aproximar-se mais do ponto crítico A é necessário realizar uma redução de passo. Entretanto, não é possível, devido à singularidade de *J*, ultrapassar este ponto se a condição inicial anterior se encontrar antes do mesmo. Com uma condição inicial adequada, isto é, um ponto convergido ou um estado inicial escolhido que esteja muito próximo de uma solução de baixa tensão, portanto além do ponto A (PMC), pode-se traçar o restante da curva,

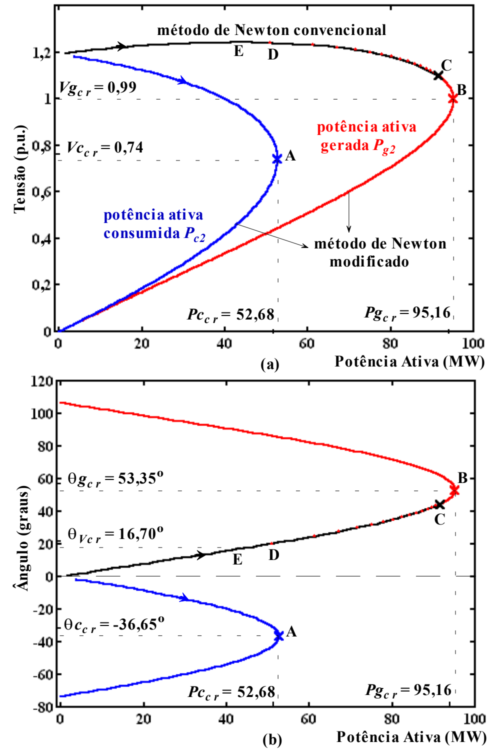

FIGURA 3
MÉTODO DE NEWTON MODIFICADO.

bastando para isso, usar passos negativos, ou seja, diminuir o valor da potência ativa. Caso similar acontece com o método parametrizado por tensão quando do traçado da curva de *Pg*, só que com relação ao seu respectivo ponto de singularidade, ponto E. Neste caso, o valor da tensão crítica, no caso tensão máxima, pode ser obtido de (32) fazendo-se $dP_2/dV_2 = \infty$, o que leva à condição $\sqrt{V_2^2 V_1^2 y_{12}^2 - b_{12}^2 V_2^4} = 0$, de onde se obtém o valor crítico para a tensão $Vg_{2Vcr} = z_{12}V_1/x_{12}$ = 1,243 p.u., o qual após a substituição na equação (26) fornece a respectiva potência crítica $Pg_{2Vcr} = r_{12}V_1 / x_{12}^2 = 42{,}483$ MW. Quanto ao ângulo crítico, pode-se obtê-lo, por exemplo, da condição de que o $det| J_m |$ = 0, ou seja, $\partial Q_2 / \partial\theta_2 = y_{12}V_1V_2 \cos(\theta_2 + \phi) = 0$, de onde se obtém θg_{2Vcr} = 90º – ϕ = 16,70º. Observa-se que partindo do *flat-start* (estimativa inicial onde todos os ângulos são assumidos iguais a zero e as tensões iguais a 1,0 p.u.) e incrementando a tensão de 0,01 em 0,01 p.u., é possível aproximar-se do ponto E, mas não ultrapassá-lo. Se após aproximar-se de E, com sucessivas reduções no valor do incremento do passo, tentar-se diminuir a tensão, retornar-se-á pelo mesmo caminho. A solução seria, por exemplo, ou partir de um ponto convergido que se encontra além deste ponto obtido por um FC convencional, como foi o caso (ponto D), ou ao aproximar-se do ponto, e em função do aumento do número de iterações, mudar de método. Esta última opção é apresentada posteriormente. Observa-se que estas mesmas curvas foram obtidas com (29) da parte I [1].

Quanto ao uso do ângulo como parâmetro, pode-se verificar da condição de que o *det* $|J_m|$ = 0, isto é, $\partial P_2/\partial\theta_2 = -y_{12}V_1V_2\,sen(\theta_2+\phi) = 0$ implica em $\theta g_{2Acr} = -\phi = -73{,}30^o$, e que portanto este não apresenta singularidade na região de interesse. Assim, pode-se traçar inteiramente ambas as curvas sem a necessidade de mudar de método. Isto já era esperado por se tratar de aumento de potência ativa, o qual é conseguido, principalmente, às custas do aumento da abertura angular e, consequentemente, do aumento de θ_2.

Curvas SV

Pode-se também traçar a curva SV, isto é, traçar a curva de crescimento da carga para um dado fator de potência ($fp = \cos\varphi$), o qual é mantido constante. Uma vez conhecido o ângulo do fator de potência, torna-se possível colocar tanto a potência ativa ($P_k = S_k\cos\varphi$) quanto a reativa ($Q_k = S_k\,sen\varphi$) em função da potência aparente S_k e do ângulo φ. Pode-se agora especificar tanto o ângulo θ_k quanto a tensão V_k. No entanto, nestes casos as respectivas linha e coluna *k* não mais seriam eliminadas, mas sim seriam trocadas as suas diferenciais em relação à variável anterior, V_k ou θ_k, e que agora é especificada, pelas diferenciais em relação à nova variável S_k. Outro modo mais interessante no entanto, seria o de considerar um fator de carregamento λ e dois outros fatores pré – especificados, K_p e K_q, os quais possibilitam a generalização do processo para o aumento de carga numa barra *k* especifica. As potências ativas e reativas escritas em função destes novos fatores seriam $P_k = \lambda\times K_p\times S_k\cos\varphi$ e $Q_k = \lambda\times K_q\times S_k\,sen\varphi$, respectivamente. Com isso, qualquer uma das curvas anteriores (PV: com K_q = 0; ou QV: com K_p = 0) inclusive agora a curva SV (incluindo também ângulos de fatores de potência diferentes de φ), pode ser obtida através da especificação ou da tensão (V_k) ou do ângulo (θ_k) da barra *k*. As curvas são obtidas considerando agora a nova variável λ e assim, na nova matriz *J*, denominada por J_m, não são eliminadas as respectivas linha e coluna *k*, mas sim conforme já comentado, substituem-se as respectivas diferenciais com relação a variável escolhida como parâmetro (a tensão V_k ou o ângulo θ_k, variável independente) pelas diferenciais com relação à nova variável λ. Assim sendo, para o sistema de duas barras p. ex., usando a tensão da barra *2* (V_2) ou o ângulo da tensão da barra *2* (θ_2) como parâmetro a equação resulta, respectivamente:

$$\begin{bmatrix}\Delta P_2\\ \Delta Q_2\end{bmatrix} = \begin{bmatrix}\partial P_2/\partial\theta_2 & \partial P_2/\partial\lambda\\ \partial Q_2/\partial\theta_2 & \partial Q_2/\partial\lambda\end{bmatrix}\begin{bmatrix}\Delta\theta_2\\ \Delta\lambda\end{bmatrix} = \begin{bmatrix}\partial P_2/\partial\theta_2 & -K_pS_2\cos\varphi\\ \partial Q_2/\partial\theta_2 & -K_qS_2\,sen\,\varphi\end{bmatrix}\begin{bmatrix}\Delta\theta_2\\ \Delta\lambda\end{bmatrix} \quad (38)$$

e

$$\begin{bmatrix}\Delta P_2\\ \Delta Q_2\end{bmatrix} = \begin{bmatrix}\partial P_2/\partial\lambda & \partial P_2/\partial V_2\\ \partial Q_2/\partial\lambda & \partial Q_2/\partial V_2\end{bmatrix}\begin{bmatrix}\Delta\lambda\\ \Delta V_2\end{bmatrix} = \begin{bmatrix}-K_pS_2\cos\varphi & \partial P_2/\partial V_2\\ -K_qS_2\,sen\,\varphi & \partial Q_2/\partial V_2\end{bmatrix}\begin{bmatrix}\Delta\lambda\\ \Delta V_2\end{bmatrix} \quad (39)$$

Observe que agora as curvas PV (fp=1, isto é, K_p=1 e K_q=0, Figuras 2(a)) e QV (fp=0, isto é, K_p=0 e K_q=1, Figuras 2(b)), as demais curvas passam a ser casos particulares da metodologia empregada para traçar a curva SV. Os valores críticos para potência, tensão e ângulo, podem ser obtidos de (23) a (28), respectivamente, enquanto que o traçado das curvas pode ser obtido de (31), apresentadas na parte I [1].

CONCLUSÕES

Neste trabalho são apresentados e avaliados os métodos de Newton convencional e propostos, considerando as variações de cargas numa única barra. Observa-se que os métodos propostos são casos especiais do método da continuação. A técnica usada para o traçado da curva QV, p. ex., faz uso da técnica de parametrização local com previsão trivial ou polinomial modificada de ordem zero [7]. No caso, $\lambda = Q_k$ (potência reativa da barra *k*), e a tensão do gerador fictício V_k é utilizada como parâmetro. Assim, a solução sucessiva das equações do FC pelo método de Newton com a prefixação de vários valores para o parâmetro em uso (λ, θ_k, ou V_k) são casos particulares dessa técnica de previsão. Dessa forma, todos os casos anteriores podem ser considerados como uma particularidade do método da continuação [4]. Ao incluir-se λ como variável, as equações do FC passam a ter (n+1) variáveis para *n* equações. Assim, pode-se definir qualquer uma das n+1 variáveis como parâmetro. O valor deste parâmetro (θ_k, V_k ou até mesmo λ) pode ser especificado e, portanto, removido do sistema. Assim, passa-se a ter novamente *n* equações a *n* incógnitas. A escolha adequada do parâmetro em função daquele que apresentar a maior taxa de variação durante o traçado da curva costuma ser o suficiente para eliminar a singularidade da matriz Jacobiana. Esta troca de variáveis corresponde à rotação de 90º do diagrama θ_k versus λ, ou V_k versus λ [7].

ANALISANDO UM CIRCUITO ELETRÔNICO LINEAR EM TEMPO CONTÍNUO E EM TEMPO DISCRETO

Renan S. Duque[1], Fábio A. R. Nascimento[2], Wilton N. A. Pereira[3], Maurício Silveira[4], Sandro A. Fasolo[5] e Francisco J. Fraga[6]

Resumo *— Este artigo consiste na análise do comportamento de um filtro digital FIR, implementado em hardware e simulado em software, associando-o aos conceitos de sinais e sistemas. A simulação foi feita utilizando o software Mathcad 2001 Professional e a implementação em hardware foi feita através do kit da família Motorola DSP56000.*

Abstract – *This paper treats the analysis of the behavior of a digital FIR filter, implemented in hardware and simulated in software, associating it to the signals and systems concepts. The simulation was implemented using Mathcad 2001 Professional software and the hardware was implemented using the Motorola DSP56000 family kit.*

Index terms — Kit DSP, Causalidade, Motorola DSP56000, Sinais e Sistemas.

INTRODUÇÃO

O circuito a ser implementado em hardware e simulado em software é um filtro digital passa-faixa tipo FIR (Finite Impulse Response), excitado por um sinal digital obtido através da amostragem, na frequência fs = 9600 (Hz), de um outro sinal composto por três senoides contínuas, cada uma com sua frequência particular, assim estipuladas: f1 = 223 (Hz), f2 = 1031 (Hz) e f3 = 3419 (Hz). As Figuras 1 e 2 a seguir ilustram o diagrama simplificado do projeto e a resposta desejada para o filtro passa-faixa, respectivamente.

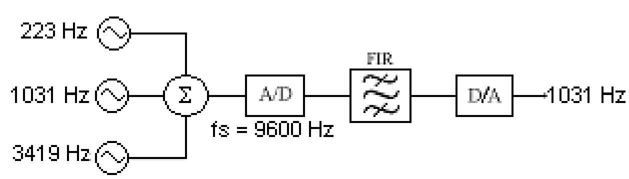

FIGURA. 1
DIAGRAMA EM BLOCOS DO PROJETO

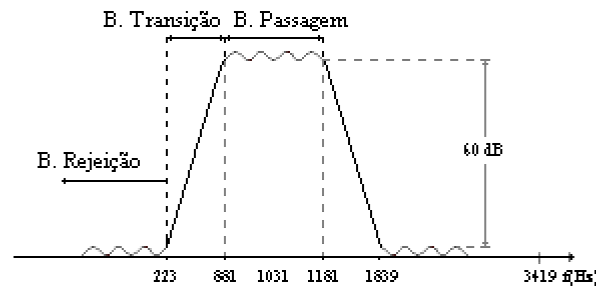

FIGURA. 2
ESPECIFICAÇÕES DO FILTRO PASSA-FAIXA DIGITAL FIR

Utilizando os conceitos de Sinais e Sistemas e contando com um software de apoio em cálculo numérico, podemos facilmente projetar e simular o circuito acima, facilitando a análise de seu comportamento. Para tal, utilizamos o software Mathcad 2001 Professional®. Nele geramos os sinais de entrada do filtro, definimos a sua função de transferência e obtivemos os resultados de saída. Todos os resultados puderam ser numérica e graficamente analisados, como veremos adiante.

No caso da implementação em hardware, geramos e somamos as três senoides através do software VisSim® e exportamos o sinal resultante para um arquivo tipo WAV, que pode ser executado e enviado para a saída da placa de som do computador. A digitalização do sinal, a filtragem e a conversão de digital para analógico novamente pôde ser obtida com um único circuito, conhecido como Kit DSP; no nosso caso, utilizamos um produzido pela Motorola.

CONCEITUAÇÃO BÁSICA

As razões básicas devido às quais não se pode implementar um filtro ideal, por exemplo passa-baixas, são os fatos de a resposta ao impulso desse filtro não atender ao princípio da causalidade e não ter comprimento finito ao longo do eixo do tempo. Para contornar o problema do comprimento infinito da resposta ao impulso somos compelidos a

implementar um truncamento em determinado ponto dessa resposta, a prejuízo de uma oscilação, tanto na banda de rejeição, como na banda de passagem da resposta em frequência do filtro. No caso de contornar o problema com o princípio da causalidade, faz-se necessário implementar um atraso na resposta impulsiva temporal, deslocando-a de modo que a extremidade negativa coincida com o ponto de zero do eixo do tempo. Este atraso, causa, forçosamente, uma defasagem linear ao longo do eixo de frequência da resposta do filtro [1].

A Figura 3 ilustra a resposta impulsiva do filtro, truncada e atrasada, devido a necessidade de aproximação para a resposta ideal de um filtro passa-baixas digital.

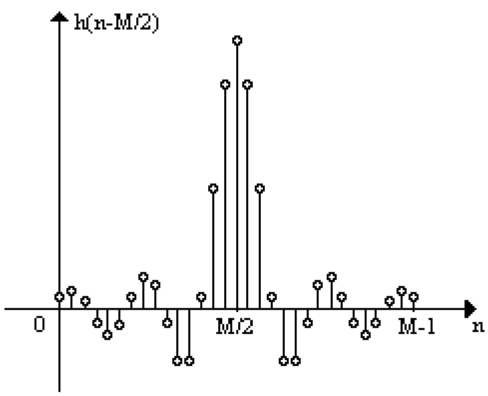

FIGURA. 3
RESPOSTA IMPULSIVA TRUNCADA E ATRASADA DE UM FILTRO DIGITAL PASSA-BAIXAS REAL

A Figura 4 ilustra o que acontece no módulo e na fase da resposta em frequência do filtro passa-baixas digital quando truncamos e deslocamos as amostras da resposta ao impulso no domínio do tempo. Note-se a ondulação nas bandas de passagem e rejeição, bem como a alteração na fase da resposta em frequência.

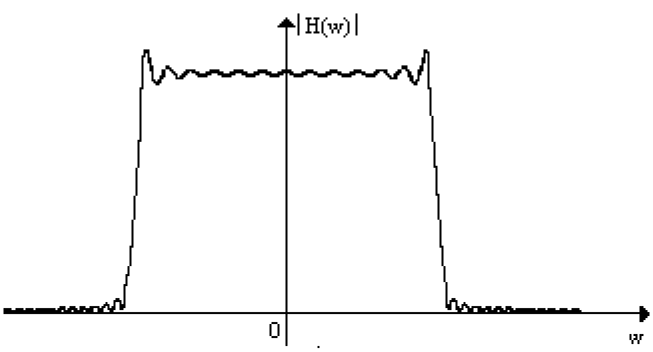

FIGURA. 4
MÓDULO DA RESPOSTA EM FREQUÊNCIA DO FILTRO PASSA-BAIXAS DIGITAL REAL AO TRUNCAR-SE A RESPOSTA TEMPORAL AO IMPULSO

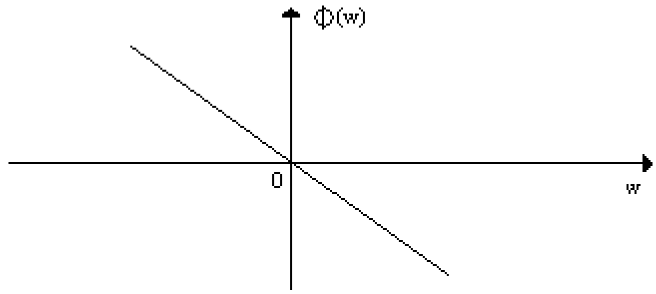

FIGURA. 5
FASE DA RESPOSTA EM FREQUÊNCIA DO FILTRO PASSA-BAIXAS DIGITAL REAL AO DESLOCAR-SE A RESPOSTA TEMPORAL AO IMPULSO

O objeto principal de nosso estudo é o filtro digital FIR e, por isso, não abordaremos as questões complementares desse projeto, como os conversores *A/D e D/A*, o somador, a geração das senoides etc., partindo agora para uma abordagem mais detalhada do filtro em si, começando pelo seu equacionamento, tanto no domínio do tempo quanto no da frequência.

No domínio do tempo, o sinal de saída do filtro linear e invariante no tempo é a convolução da sua resposta ao impulso com o sinal de entrada [2], sendo representada por:

$$y[n] = x[n] * h[n] \tag{1}$$

$$y[n] = \sum_{k=-\infty}^{\infty} h[k]x[n-k] \tag{2}$$

$$y[n] = \sum_{k=-\infty}^{\infty} h_k x[n-k] \tag{3}$$

onde $y[n]$ é o sinal de saída, $x[n]$ é o sinal de entrada e $h[n]$ é a resposta ao impulso do filtro.

No domínio da frequência, o sinal de saída do filtro linear e invariante no tempo é a multiplicação da função de transferência do filtro pelo seu sinal de entrada, na forma:

$$Y(z) = H(z)X(z) \tag{4}$$

$$H(z) = \sum_{k=-\infty}^{\infty} h[k]z^{-k} = \sum_{k=-\infty}^{\infty} h_k z^{-k} \tag{5}$$

$$Y(z) = \sum_{k=-\infty}^{\infty} h_k z^{-k} X(z) = \sum_{k=-\infty}^{\infty} h_k \left[z^{-k} X(z)\right], \tag{6}$$

onde $Y(z)$ é o sinal de saída, $X(z)$ é o sinal de entrada e $H(z)$ é a função de transferência do filtro.

Note-se que voltando (6) para o domínio do tempo, obtemos (3), que, neste caso é a própria equação de diferenças do filtro.

Expandindo tal equação de diferenças, temos:

$$y[n] = h_0 x[n] + h_1 x[n-1] + h_2 x[n-2] + \ldots, \quad (7)$$

Vimos, porém que a resposta impulsiva é truncada, então, a equação (7) pode ser rescrita por:

$$y[n] = h_0 x[n] + h_1 x[n-1] + \ldots + h_{M-1} x[n-M+1] \quad (8)$$

onde $(M-1)$ é a última amostra da resposta impulsiva $h[n]$, ou h_n. Vemos que essa equação sugere uma implementação direta, conforme ilustra o diagrama em blocos da Figura 6 [1]:

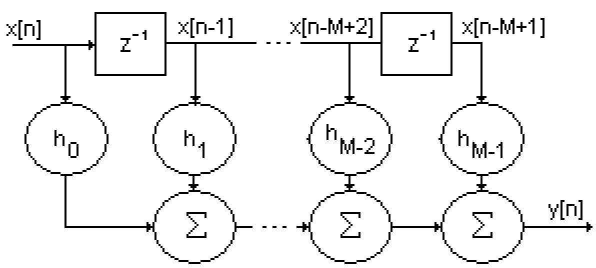

FIGURA. 6
IMPLEMENTAÇÃO DA EQUAÇÃO DE DIFERENÇAS NA FORMA DIRETA

PROJETO

O truncamento da resposta impulsiva temporal do filtro pode ser empregado através de técnicas muito mais elaboradas e vantajosas do que a simples consideração do sinal de resposta dentro de um intervalo de tempo. Tais técnicas são conhecidas como técnicas de janelamento, existindo diversas delas, cada qual, com características próprias, visando uma particularidade no funcionamento e na complexidade do circuito. No nosso caso, aplicaremos a janela de Kaiser, que apresenta a melhor relação entre a atenuação desejada para a banda de rejeição e a ordem do filtro (ou o número de amostras M consideradas na resposta impulsiva do filtro), que determina o tempo de processamento do circuito.

Seja $w[n]$ a função que define a janela de Kaiser [1]:

$$w[n] = \begin{cases} \dfrac{I_0\left[\beta\left(1-[(n-\alpha)/\alpha]^2\right)^{1/2}\right]}{I_0(\beta)} & 0 \le n \le M-1 \\ 0 & n<0,\ n>M-1 \end{cases} ,(9)$$

onde:

$$\beta = \begin{cases} 0{,}1102(A-8{,}7) & A>50 \\ 0{,}5842(A-21)^{0{,}4} + 0{,}07886(A-21) & 21 \le A \le 50 \\ 0 & A<21 \end{cases}, \quad (10)$$

$$\alpha = (M-1)/2, \quad (11)$$

$A =$ Atenuação entre a banda de passagem e a banda de rejeição,

$$M-1 = \frac{A-7{,}95}{2{,}285\Delta w}, \quad (12)$$

$\Delta w =$ largura da banda de transição, ou seja, a banda entre a frequência de rejeição e a frequência de passagem, em radianos.

Neste ponto já obtemos a função de janelamento $w[n]$ que vai ser multiplicada ponto a ponto pela reposta impulsiva de um filtro passa-faixa ideal, atrasada de $(M-1)/2$ amostras, gerando-se assim, a resposta impulsiva janelada e deslocada do filtro real. Com isto obtemos também a resposta em frequência do filtro real, que é uma aproximação da resposta ideal, pagando-se o preço imposto pelo janelamento e pelo truncamento. A seguir, veremos os resultados das simulações em software desse projeto.

SIMULAÇÃO EM SOFTWARE

Os resultados que obtivemos para $w[n]$ estão ilustrados a seguir:

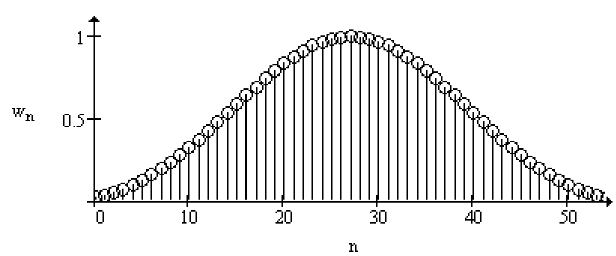

FIGURA. 7
REPRESENTAÇÃO GRÁFICA DA JANELA DE KAISER PARA A=60DB

Entenda-se por h_{d_n} a resposta impulsiva do filtro ideal atrasada, representada na figura 8 por uma linha e h_{pf_n} a resposta impulsiva h_{d_n} multiplicada pela janela de Kaiser $w[n]$, representada também na Figura 8 pelas amostras:

IMPLEMENTAÇÃO EM HARDWARE

O diagrama da Figura 6 foi implementado fazendo-se uso de um microprocessador especial para processamento digital de sinais, em forma, basicamente, de instruções *MAC* [3]. A instrução *MAC* (Signed Multiply-Acumulate) executa uma multiplicação entre seus dois primeiros operandos, que são data sources, no nosso caso de 24 bits e adiciona o resultado ao acumulador de destino, no nosso caso de 56 bits. Sendo assim, o processador armazena as *M* amostras mais recentes do sinal (onde *M* é a ordem do filtro) em algum lugar da memória *Y*, por exemplo; armazena todos os coeficientes h_n, em algum lugar da memória *X*, por exemplo e multiplica cada amostra de entrada pelo seu fator h_n correspondente, acumulando-se o resultado dessas multiplicações no acumulador *A*, por exemplo. Ao final, temos uma saída *y[n],* que é a soma acumulada de todas as multiplicações, termo a termo, de h_n pela sua amostra de entrada correspondente, resultando assim no sinal de saída *y[n]* que é o sinal de entrada *x[n]* filtrado.

Nos servimos de um kit completo de DSP, com o propósito de pudermos aproveitar ainda a facilidade de utilizar o conversor *A/D* e *D/A* do próprio kit, a fim de discretizarmos o sinal de entrada *x(t)* e obtermos *x[n]*.

As rotinas de inicialização do processador, de comunicação entre os conversores e o processador etc. são fornecidas juntamente com a documentação do Kit e carecem de pequenos ajustes, como por exemplo: sinal stereo ou mono, frequência de amostragem, etc. [3][4][5][7].

A Figura 14 ilustra o diagrama simplificado de um Kit DSP[4].

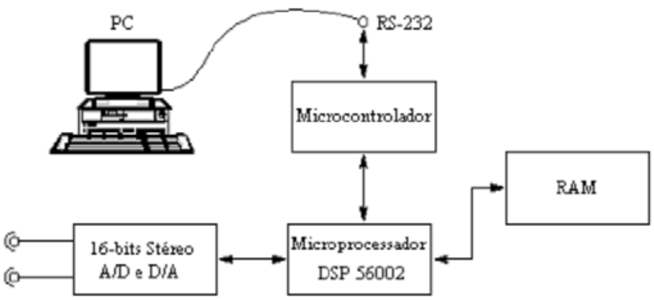

FIGURA. 14
DIAGRAMA SIMPLIFICADO DE UM KIT DSP

As vantagens que encontramos na utilização de um kit DSP, em relação a de um outro hardware convencional são, entre outras, tolerâncias menores (ausência de ajustes) e flexibilidade de implementação de mudanças eventuais no projeto. Uma outra grande vantagem foi a utilização de um conversor *A/D-D/A* já embutido no kit e apropriadamente ajustado ao DSP. Além disso, as rotinas em assembly para comunicação e controle entre o *A/D-D/A* e o DSP são facilmente obtidas na própria documentação do kit. Outra facilidade ainda é o fato de o kit trazer como suporte um programa depurador [5], que facilita o rastreio de problemas nas rotinas e promove a gravação delas do PC para o DSP, via interface RS-232.

Para fins didáticos seria ideal a implementação de uma via paralela analógica, capaz de realizar a mesma função do filtro FIR. Esta parte do projeto foi idealizada mas não pôde ser concluída e será alvo de um estudo futuro.

CONCLUSÕES

O objetivo fundamental deste artigo é apresentar um projeto de um filtro do ponto de vista educacional e poder complementar a necessidade do aluno com alguns fundamentos teóricos ligados à comunicação digital. Entre estes, podemos destacar a Transformada de Fourier de Tempo Discreto, Transformada Z, operações inversas, algumas propriedades tais como convolução, deslocamento no tempo e na frequência, linearidade etc. Houve também a necessidade de um estudo apurado de função de transferência, amostragem e equação de diferenças [6]. Nota-se, então, a grande relação entre estes conceitos abordados em um curso de Sinais e Sistemas e os projetos dos filtros digitais FIR.

A simulação em software facilitou sobremaneira a fixação dos conceitos obtidos pelo aluno em sala de aula, visto que é uma aplicação direta, na forma de cálculo numérico. Além disso, propicia ao aluno uma base sólida para implementação do projeto em hardware e comparação de resultados.

O trabalho com o hardware aproximou de maneira altamente positiva os conceitos da teoria à prática. Avaliamos ser esta uma necessidade preemente em todas as disciplinas de um programa de pós graduação, pois o aluno sempre encontra uma barreira considerável entre a simulação e a implementação.

AGRADECIMENTOS

Nossos agradecimentos sinceros aos professores Fabiano Valias Carvalho e José Panaro e também às instituições FINATEL e ERICSSON pelo apoio.

ANÁLISE DE COMPONENTES NÃO LINEARES OPERANDO COM MÚLTIPLAS PORTADORAS

Moacir Maffioletti Júnior[1], *Carlos Nazareth Motta Marins*[2], *Maurício Silveira*[3], *Wilton Ney do Amaral Pereira*[4], *José Antônio Justino Ribeiro*[5]

I. Introdução

Os sistemas de comunicação estão sendo cada vez mais exigidos no mundo moderno. E as operações com altas taxas de transmissão devem ser aliadas ao máximo desempenho de energia com a menor deterioração do sinal, no intuito de oferecer confiabilidades cada vez mais elevadas.

Por este motivo, as modulações estão se tornando cada dia mais sofisticadas e o processamento de múltiplas portadoras de forma simultânea nos equipamentos de transmissão e recepção, estão se tornando práticas comuns em sistemas via satélite, sistemas de comunicação móvel, sistemas digitais de TV, entre outros.

Por este motivo, este trabalho abordará a não linearidade de elementos utilizados nas diferentes funções dentro da estrutura de rádio.

Com esta ferramenta pode-se simular o comportamento do elemento sob análise, com diferentes níveis de potência e com diferentes componentes de sinais em diferentes freqüências, ou seja, pode-se simular o dispositivo operando com múltiplas portadoras.

Para o ambiente acadêmico e profissional este trabalho resultará em um software que ajudará aos projetistas de amplificadores, misturadores (mixers) e outros circuitos, conhecerem o nível dos produtos de intermodulação com uma ou mais portadoras e consequentemente seus efeitos no domínio do tempo e da freqüência.

II. Sistemas Lineares

Um Sistema Linear é aquele que responde a um sinal de entrada sempre com a mesma proporção em amplitude e fase, independente mente do nível com que o mesmo é aplicado à sua entrada.

Um sinal composto por múltiplas portadoras, ocupa uma banda ao longo do espectro de freqüências, se este sinal for aplicado a um sistemas linear, o mesmo poderá sofrer distorções, pois sua resposta a cada uma das componentes não necessariamente deve ser igual em amplitude e ou fase.

Um filtro é um Sistema Linear que não responde da mesma forma à todas as componentes do espectro de freqüências, mas sempre responderá a um determinado sinal da mesma forma em amplitude e fase, independentemente do nível assumido pelo mesmo em sua entrada.

O Sistema Linear pode ainda ser definido como, sendo aquele que não introduz outras componentes harmônicas a partir dos sinais originais aplicados à sua entrada.

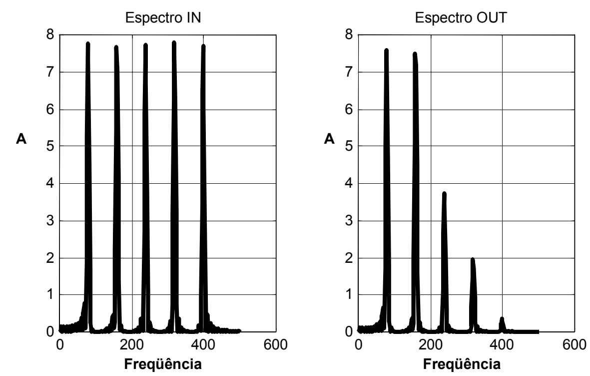

Figura 1 – *Resposta de um Sistema Linear (filtro) no domínio da freqüência.*

Na *Figura 1*, tem-se o comportamento de um filtro que altera as características das componentes de um sinal sem gerar espúrios ou harmônicas.

III. Função de Transferência de um Sistema Linear

Um Sistema Linear, quando excitado por um sinal senoidal de freqüência determinada, oferece na saída um sinal senoidal de mesma freqüência, mas que pode ter amplitude e fase diferentes das do sinal de excitação.

Um Sistema Linear ideal é aquele que permite transmitir qualquer sinal sem imprimir-lhe deformações.

Comparando-se a saída r(t) do sistema com a entrada f(t), podemos admitir uma variação de escala, em amplitude,

$$r(t) = K * f(t) \qquad (01)$$

onde k = constante

[5] José Antônio Justino Ribeiro, justino@inatel.br

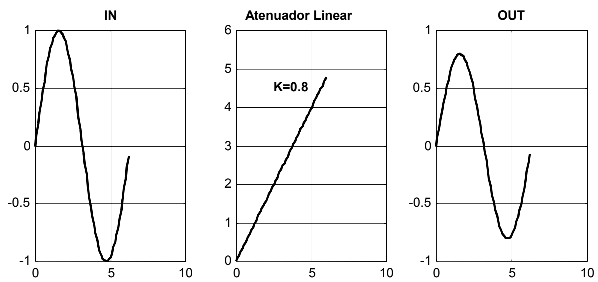

Figura 2 – *Sinais de entrada e saída de um Sistema Linear.*

Define-se a "*função de transferência*" do sistema como a relação entre as transformadas dos sinais de saída e de entrada.

$$G(j\omega) = \frac{R(j\omega)}{F(j\omega)} \qquad (02)$$

Demonstra-se que a função de transferência depende exclusivamente dos componentes de circuito que compõe o sistema, podendo ser calculada diretamente a partir dos mesmo.

A função de transferência fornece as informações de como o sistema atua sobre as componentes de freqüência do sinal de entrada.

A resposta do sistema ao sinal de entrada pode apresentar um retardo t_0, sem que nenhuma alteração ocorra na amplitude ou freqüência da forma de onda, descaracterizando o sinal original.

$$r(t) = K * f(t - t_0) \qquad (03)$$

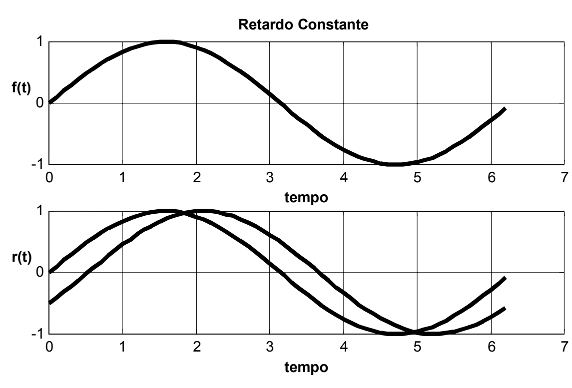

Figura 3 – *Medida do retardo em Sistemas Lineares*

Até este ponto considerou-se a variação da resposta de amplitude ao longo da faixa de resposta do sistema no domínio da freqüência, com retardo constante.

A defasagem introduzida seguia uma lei linear com a freqüência, mas mesmo sendo a resposta em amplitude constante, se a resposta em fase não for linear, isto é, se o retardo para todas as componentes não for constante, haverá igualmente distorção do sinal, caso este seja composto por múltiplas componentes.

A função de transferência G(ω) do sistema, será expressa na forma complexa:

$$G(\omega) = K * \varepsilon^{j\phi(\omega)} \qquad (04)$$

onde a defasagem introduzida pelo sistema sobre as componentes será supostamente linear, isto é:

$$\phi(\omega) = -\omega . t_0 \qquad (05)$$

em que t_0 é o tempo de retardo considerado igual para todas as componentes.

Para o sistema linear, em que $t_0 = 0$, não é introduzido nenhum tipo de retardo no sinal de saída.

A defasagem relativa $\phi(\omega_2)$ - $\phi(\omega_1)$ de uma componente em relação a outra, pode ser medida através da expressão (06). Esta medida é realizada comparando-se as fases na saída para as duas componentes, conhecendo as condições de fase na entrada do sistema.

$$\phi(\omega_2) - \phi(\omega_1) = (-\omega_2 t_0) - (-\omega_1 t_0) = -(\omega_2 - \omega_1) t_0 \qquad (06)$$

$$\frac{\Delta\phi(\omega)}{\Delta\omega} = \frac{\phi(\omega_2) - \phi(\omega_1)}{\omega_2 - \omega_1} = -t_0 \qquad (07)$$

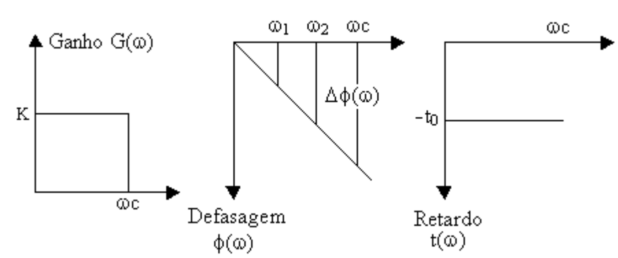

Figura 4 – *Análise de retardo e fase em Sistemas Lineares*

Quando o espectro útil do sinal estiver situado entre os limites da faixa de passagem do sistema, o efeito da atenuação na transmissão é pouco significativo, por isto, na engenharia de sistemas é comum se analisar primeiro a largura de faixa do sinal e então selecionar ou projetar o sistema que contemple no mínimo a faixa desejada.

Usamos a função de transferência *G(s)* do sistema para definir sua resposta ao sinal de entrada, como apresentado na *Figura 5* para os filtros e na *Figura 6* que representa a resposta de um par telefônico.

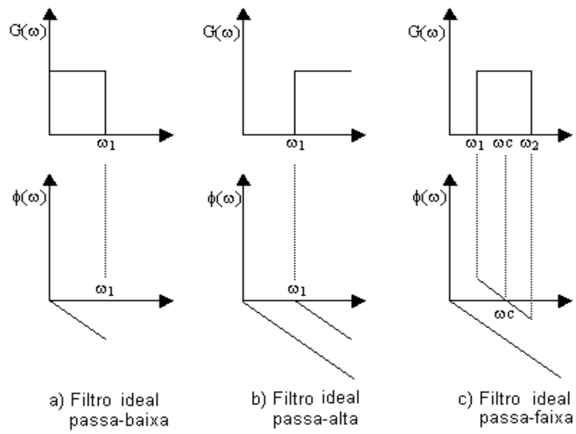

Figura 5 – *Resposta de filtros ideais*

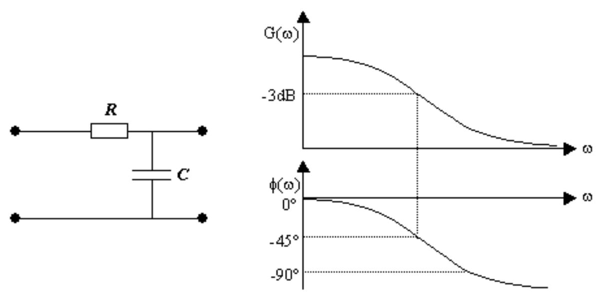

Figura 6 – *Circuito equivalente de um par telefônico*

IV. Sistemas Não Lineares

Existe para os sistemas uma relação entre amplitude do sinal de saída e a amplitude do sinal de entrada, que podemos analisar através do levantamento da chamada *característica de transferência*. É importante ressaltar que não deve-se confundir a expressão "*característica de transferência*" com a expressão *função de transferência*.

Quando o formato do sinal de saída independe da amplitude do sinal de entrada a resposta é dita linear, como pode ser visualizado na primeira parte deste trabalho.

O sistema é não linear quando a resposta é dependente da magnitude do sinal de entrada. Com isto, a *característica de transferência* se afasta do modelo linear.

A não linearidade verificada através da curva da característica de transferência, faz com que o sinal de saída apresente distorções em amplitude e novas componentes de freqüência, chamadas espúrios.

Portanto, uma característica importante do sistema não linear é a alteração do conteúdo harmônico do sinal de saída. Além destas componentes harmônicas, chamadas de espúrios ou produtos de intermodulação causarem distorções no sinal de saída, existe a possibilidade dos mesmos causarem a interferência em outros sistemas.

A *Figura 8* mostra como a distorção no domínio do tempo apresentada na *Figura 7*, pode ser analisada no domínio da freqüência.

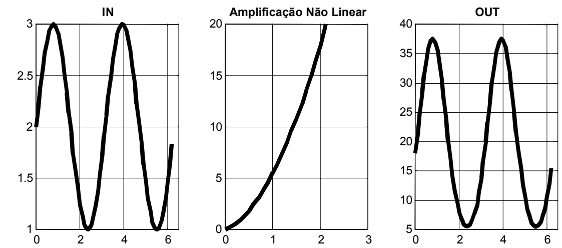

Figura 7 – *Sinais de entrada e saída de um Sistema Não Linear.*

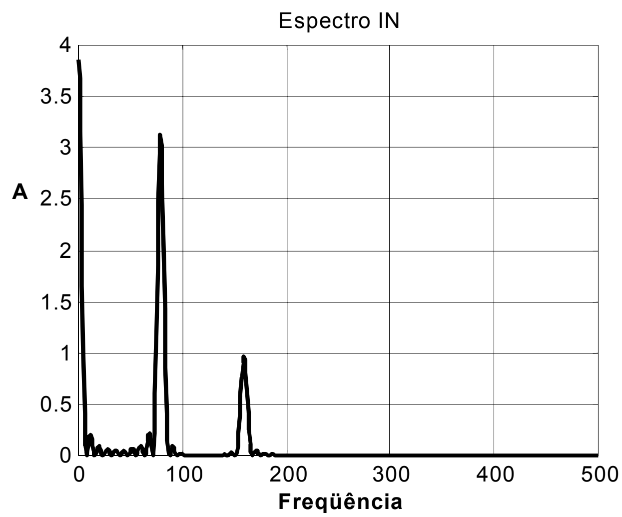

Figura 8 – *Espúrios e harmônicas geradas devido a não linearidade.*

A curva de característica de transferência pode ser desenvolvida a partir da série de Taylor em torno do ponto de operação escolhido.

$$e_0(t) = k_0 + k_1 * e_i(t) + k_2 * e_i^2(t) + k_3 * e_i^3(t) + ... \qquad (08)$$

O termo constante exprime uma componente CC e pouco pesa no resultado final, pois pode ser considerado igual a zero quando conveniente.

V. Efeitos da fase não linear

A distorção de fase ocorre quando $\phi(\omega)$ deixa de seguir uma lei linear com a freqüência. Através da equação (07) pode-se definir um retardo absoluto para cada freqüência individual ω, pela relação:

$$t(\omega) = \frac{\phi(\omega)}{\omega} \qquad (09)$$

E a distorção implica que $t(\omega)$ não seja mais uma constante e sim apenas uma função de ω.
Mesmo que a amplitude das componentes seja rigorosamente respeitada, o fato de haver retardos diferentes para diferentes componentes vai modificar a resposta, porque na soma as componentes não mais guardam a relação de fase original.

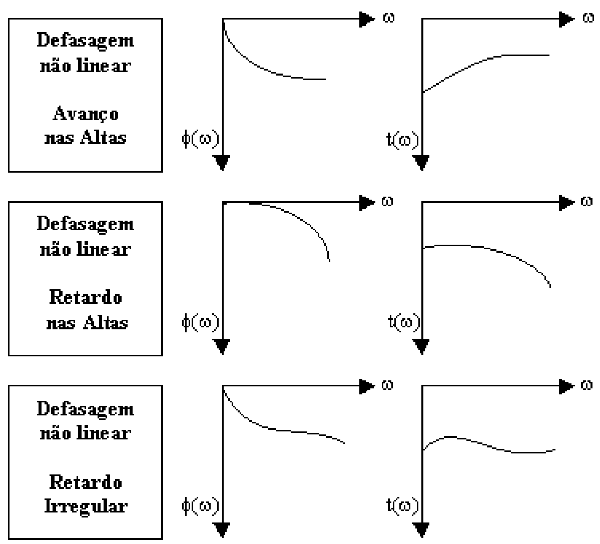

Figura 09 – *Respostas não lineares de fase*

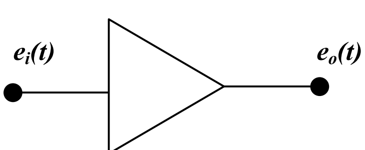
VI. Não linearidade em amplificadores.

Para amplificadores tem-se um comportamento não linear, com o termo cúbico gerando os produtos de intermodulação dentro da banda de trabalho ou nos canais adjacentes em aplicações multi-portadoras.

Analisando um amplificador com duas portadoras, pode-se perceber estes efeitos.

Supondo o amplificador da *Figura 10*, tem-se:



$$e_0(t) = k_1 e_i - k_3 e_i^{\,3}(t) \qquad (10)$$

Figura 10 - *Amplificador com comportamento não linear*

Para o espectro em análise adotou-se para a entrada (IN) as freqüências de ω_1=502 rad/s e ω_2=942 rad/s, o que corresponde respectivamente a f_1=80Hz e f_2=150Hz.

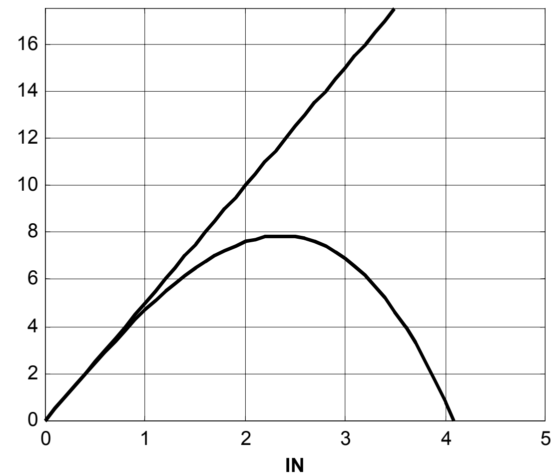


Figura 11 - *Função característica de transferência do amplificador*

$$e_i(t) = A\cos(\omega_1 t) + A\cos(\omega_2 t) \qquad (11)$$

$$e_0(t) = K_1 e_i(t) - K_3 e_i^{\,3}(t) \qquad (12)$$

$$K_1 e_i(t) = K_1(A\cos(\omega_1 t) + A\cos(\omega_2 t)) \qquad (13)$$

$$K_3 e_i^{\,3}(t) = K_3(A\cos(\omega_1 t) + A\cos(\omega_2 t))^3 \qquad (14)$$

$$\begin{aligned}
e_0(t) = &-\frac{3A^3}{4}k_3\cos((2\omega_1 - \omega_2)t) + \\
&(k_1 A - \frac{9A^3}{4}k3)\cos(\omega_1 t) + \\
&(k_1 A - \frac{9A^3}{4}k3)\cos(\omega_2 t) - \\
&(k_1 A - \frac{9A^3}{4}k3)\cos(\omega_2 t) - \\
&\frac{3A^3}{4}k_3\cos((2\omega_2 - \omega_1)t) - \qquad (15)\\
&\frac{A^3}{4}k_3\cos(3\omega_1 t) - \\
&\frac{3A^3}{4}k_3\cos((2\omega_1 + \omega_2)t) - \\
&\frac{3A^3}{4}k_3\cos((2\omega_2 + \omega_1)t) - \\
&\frac{A^3}{4}k_3\cos(3\omega_2 t)
\end{aligned}$$

THEORETICAL BASIS FOR MATHEMATICAL MULTIMEDIA SOFTWARE

Leonardo Galdino de Morais [1] and Alex Sandro Gomes [2]

Abstract — *In this paper, we analyse the state-of-the-art of multimedia applications in the teaching of Mathematics. It will be studied in the light of the Theory of Conceptual Fields [1]Several works demonstrate that the educational softwares developed for the teaching of Mathematics tend to present a limited number of cases (Balacheff e Kaput, 1996; Schwartz, 1999; Hinostroza e Mellar, 2001). We believe that this is due to intrinsic limitations of the interfaces, which employ only graphical resources and direct manipulation. We shall discuss the main improvements in this area and present a model for the production of multimodal interfaces – those with multiple integrated forms of presentation, such as video and animation – oriented by a constructivistic proposal of cognitive development learning in this area.*

INTRODUCTION:

There is a plethora of educational software for the teaching of Mathematics available in the market, the majority strives to teach through successive repetitions of the solving of problems of the same type. At the end of this "marathon of exercices", the pupil feels that he has learned something. Such sensation can't stant modifications in the style of the questioning making it clear that, instead of learning the real contents, the student was simply trained to solve problem of a given pattern. According to Mayes [2], learning is the product of other activities. In this context, it is necessary to define and validate the models and methodologies that identify and evaluate the activities that cal help the student to learn, and translate these activities into educational software. We noticed the need of creating rich contexts, a wide repertory of situations, and the need of providing interfaces flexible enough to allow the emergence of multiple heuristics for the solving of problems in this conceptual field.

One of the characteristics of Mathematics is that its concepts are buildt on other concepts. The structure is not like a tree with many branches, but as a scaffold with many interconexions. Once the base of the scaffold is on a stable place it is not difficult to build it higher, but it is impossible to build one layer before the previous is finished. Due to this structure, it is almost always necessary that the teacher to impose some structure on the learning process. Our focus follows the Constructivistic Cognitive Theory.

THE LEARNING OF MATHEMATICS

The construtivism is rooted on the Piaget's works on the cognitive development of children and teenagers. His cognitive theory employs stages of development: starting with the senso-motor stage (which precedes speech) up to the stage where formal operations are performed. In this stage the child is capable of hypothetical-deductive reasoning [3]. Robert Shwarzenberger [4]observed that it is a reasonable hypothesis to suppose that the various cognitive mechanisms which control the childrens' individual learning are not different, qualitatively speaking, from the students'.

The Constructivistic Theory separaters training from teaching. In the first, the student is trained to produce an appropriate answer. The teacher imposes what is right or wrong, and the students absorb these facts, or not (which usually happens). The Construtivism asserts that teaching aims to produce autonomous understanding, and this shoud be the result of the student's mental process.

An important theoretical reference for the learning of Mathematic is Vergnaud's Theory of Conceptual Fields [1], according to which a concept is defined from three instances: its invariant properties, the systems of representation, and the instructions of use. Therefore, learning a mathematical concept implies to command a set of properties that emerge from different situations, and are mediated by different systems of representation. To command a conceptual field means to be capable of solving problems in different situations in which a concept is inserted.

The concept, the second element analysed in the represention process, and which assumes, in this work, an important position, is defined by Vergnaud [1]as a "tripod of sets"- the first set, named "S", containing the situations that convey meaning to the concept; the second, "I", containing the invariants on which the operationality of the schemes (meaning) is based; and "Y", the set containing the systems of representation, languages, which allow to represent symbolically the concept "Y" (significant). The situations ae aspects related to the deeper structure of the problems, and do not simply correspond to the contexts of the problems but to the relations between the quantities (numbers) which should occur to the subjects at the moment when they are organizing their actions for the tackling of the problems. The second element of the tripod is the set of the invariants

When interacting with real world, the individual will set in motion the knowlegde he has at that moment. The

E-mail asg@cin.ufpe.br

knowledge that emerges simultaneous to the actions are the invariant operatives, defined as the subject's knowledge that is subjacent to his behaviours, and that are, then, an integral part of his schemes of action. The articulated knowledge is, then, fragments of concepts which are employed in situations. The third component of the concept is that of symbolization, or significant. It is the way the individual is capable of expressing his thoughts. According to Vergnaud [1], there are at least six different types of situations involving these concepts; which must be completely mastered in order to be a real understanding of the conceptual field. They are:

TABLE 1
ADDITIVE SITUATIONS

I. Composition of measures - Ex: John has 12 shuttlecocks, and Peter 17. How many shuttlecocks they have together? There are two quantities given simultaneously, which the individual must start with to find a third quantity.	II. Transformation of measure - Ex.: Mary had 23 bombons. At the end of the day, she noticed that she had only 17 left. How many sweets bombons Mary ate on that day? The inicial and final qiuantities are known, but what is asked is the value of the variation between the first and the second moments.
III. Comparison of mesures - Ex.: I have 16 books, you have 43. How many books do you have more than I do? Once more, the quantities are known and simultaneous, aiming to compare the difference between the two (relation).	IV. Composition of transformations - Ex.: In the first match I scored 12 points, in a second match I scored 13 points. How many points did I score in all? The initial, intermediary, and final quantities are unknown. Only the transformations that take place during a span of time are known.
V. Composition of relations - Ex.: Mary is 3 years the senior of Antony. Marc is 4 years the senior of Mary. By how many years is Marc older than Antony? In this composition between two simultaneous relations, the elements are unknown but the relations are given.	VI. Transformation of relations - Ex.: *Mary had 3 toys more than John. She was given 4 more toys. Now, how many toys she has more than John?* None of the quantities are given, however, the existing relations and its alterations are known.

EDUCATIONAL SOFTWARE AND MULTIMEDIA IN THE TEACHING OF MATHEMATICS

The bibliography have been criticizing the quality of the educational software that seem not to correspond to the expectations of the teaching professionals [5]. The epistemological impact of the application of this new technology to the processes of learning and teaching is much smaller than the expected [6]. These results go against the evidence that the use of concrete materials – tangible interfaces – favours the learning of Mathematics [7]. Our hypothesis is that one of the reasons for this inefficiency is the fact that the process of designing considers certain aspects of the learning process in a superficial way, privileging aspects traditionally focused on the design of interfaces.

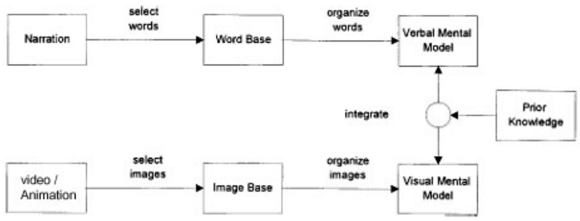
The process of educational software creation and evaluation demands the identification, or deduction of the knowledge that will probably emerge during the users' interactions with the interface, which take place in a non systematic way [8]. Having a systematic vision of the relation between the use of the interface and the actual learning implies in the use of a theoretical model of analysis that can do the modelling of the process of organization of the interaction with the interface in an understandable fashion. This modelling should happen in terms of theoretical elements that reveal the progressive adaptation of the users to the interface, and the knowledge that springs forth during its use.

The evidence gathered in our experience in the teaching of Methodology of the Teaching of Mathematics, point out that it is much simpler to negociate the meaning of mathematical relations through a dialogue than through the creation of an educational software interface. Anyway, educational interfaces are always limited when seen from the point of view of the functionalities related to the negotiation of meaning. The feedback provided are always restrictive, and in a few cases adapted to the situation experienced by the users.

Our aim is to promote a constructivistic learning, where the pupil is actively involved in the cognitive process, building significant representations and mental models.

In a constructivistic paradigm, the learning happens when the students' needs correspond to the visual and verbal representations of the memory of work at the same time. Researchers in the University of California [16] propose a multimedia learning model referenced by five principles, and by the multimedia learning cognitive theory: 1) Principle of multiple representation: it is better to present an explanation in words and graphics than only in words. This theory is corroborated by tests performed by Mayer and Anderson (1991) [17]; 2) Principle of contiguity: it is better to present words and corresponding images simultaneously than separately, offering thus a multimedia explanation; 3) Principle of coherence: multimedia explanations are better comprehended when they include only the needed information; 4) Principle of modality: it is better to present words in the form of a narration than as texts on the screen; 5) Principle of redundancy: it is better to present only animation with narration than animation, narration e and written text. The cognitive construction depends on the student's cognitive processing during the learning. The figure below shows the scheme for the Cognitive Theory of Multimedia Learning

FIGURE 1
SCHEME FOR THE COGNITIVE THEORY OF MULTIMEDIA.LEARNING



Words are represented as narrations, and images as animations or video. A cognitive apprentice will pay attention to relevant portions of the narrative (indicated by the arrow *selected words*) and will keep these words inside the verbal working memory (indicated by the box *word base*) analogously, he will pay attention to the relevant parts of the animation (indicated by the arrow *select images*) and will keep this images in the visual working memory (indicated by the box *image base*). Then , a active student will build conections mentally that organize words and images (indicated by the upper arrow that symbilizes the verbal channel, and the lower one that represents the visual channel) in a cause-effect chain (indicated by the boxes *Verbal Mental Model and Visual Mental Model*). Finally, he will build conections between the verbal and visual models, and his previous knowledge (indicated by the *integrate* structure). It is important to stress that these processes seem to take place interactively, instead of in predefined steps.

In order that a significant learning takes place, the student has to pass by each one of these cognitive processes. Selecting relevant words and images, organizing them in coherent verbal and visual representations, and integrating correspondin verbal and visual representations. All multimedia messages deliver information to the students, but not all are equally successful in promoting the understanding. The method we suggest was tested and approved by Richard E. Mayer *, Roxana Moreno [18]

ANIMATION

The theoretical foundation for the use of animation is the same for the use of static images [9]. Animations, just like static images, are considered as a subdivision of graphics in general. Pavio [10], in his dual theory of codification says that text and graphics are codified in two independent cognitive subsystems. Although keeping many similarities, animations have a series of properties, for instance, showing movement, which static images and graphics don't.

Animations have many functions. Among them we could cite: Attracting attention (when used to catch the attention); Motivating (when used as a feedback); Presenting contents (when originating from a concrete reference, and a visual context for ideas); Clarifying concepts (when propiciates a conceptual understanding even when not presenting new information). It is particularly important to catch the students' attention at the beginning of the lesson [19]. Animations can be used to attract the students' attention to key points. The clarifying function of the animation can offer an conceptual understanding even when it does not provide new information. Animations can help to exemplify abstract situations that, otherwise, would be hard to explain.

The concern in respecting preexistent patterns, in terms of the way the objetcs look in the animations, produces a positive effect in the understanding of the information presented. The coherence with other materials at the students' disposal is crucial since if the representation used in a textbook differs from the one used in the animation, this difference demands a greater cognitive effort from the student. Researches with concrete static images showed that abstract representations (schemes) are more easily remembered than concrete images [11]. On the other hand, if the goal of the instruction is a conceptual global recognition, the students will benefit from more realistic representations, such as videos.

According to Park [12], the greater the complexity of a concept, the greater the potential of understanding through the use of animation. He bases this argument on the fact that if the contents is very difficult of describing verbally, then animation can be employed effectively. [20] assert that animations help to create a mental picture of the system. When the differences between two very close concepts are not easily noticeable, then an animation can clarify the point.

VIDEO

The use of vídeo aiming at educational ends is not new. Beichner [13] reports some works on Physics performed in the 80s. Zollman [14] suggest the use of interactive vídeos as the base for laboratory tools for the modelling of complex events and qualitative analysis, among others. Other references are the work done by Marcuso and Webber [15], VideoPort (Pasço Scientific, 1999), and VideoGraph. The reasons for employing video in multimedia softwares, by its nature and the type of information it can convey, are the same for the use of animation. We can single out some advantages of the video. It allows the student to watch the real phenomenon instead of a simulation.

Research performed in laboratories for the teaching of Physics based in video show that both the students that worked with video, and the ones that worked with real experiments were able to obtain similar experimental data in the majority of experiments; in other situations, the students working with video could take advantage of the possibility of observing the phenomenon in slow motion or frame to frame. It is advisable that the pupil analyses and do the mathematical modelling starting with videos that show real situations (Rodrigues, 2001).

CONCLUSIONS

In this paper, we analysed the state-of-the-art of multimedia applications in the teaching of Mathematic. We noticed that the available bibliography in the field has a gap in dealing with the creation of interfaces that convey different contexts and situations. At the same time, it is important to offer interfaces flexible enough to allow the emergence of multiple heuristics in this conceptual field in order to produce an autonomous understanding stemming from the student's mental processes. The use of animation and videos associated to narrations propitiates greater assimilation of the contents presented, making them more efficient for the task of negociating themeaning of mathematical concepts. The animations can be used to build representations in order to facilitate the emergence of mental models. Presenting the problems with videos that picture the real world behind the mathematical concepts brings it closer to the students, and eliminates the possibility of double meanings in the interpretation of the real problem to be solved.

EDUCAÇÃO À DISTÂNCIA POR TELECONFERÊNCIA INTERATIVA

Pedro Luiz de Oliveira Costa Neto[1]

Resumo — *A partir de meados da década de 90, o ensino à distância teve considerável impulso no Brasil, mediante o uso de novas tecnologias de comunicação. Desde então, grande parte das iniciativas surgidas, mormente no campo acadêmico, têm-se utilizado principalmente da videoconferência e da Internet. Essas mídias, como as demais, têm suas vantagens e dificuldades, deixando uma lacuna que estamos pretendendo eliminar com o uso de uma terceira, a teleconferência interativa, por processo ainda inédito em nosso país, usando a via satelital. O objetivo do presente trabalho é apresentar e discutir uma experiência pedagógica coordenada pelo autor, realizada de outubro a dezembro de 2002, usando a teleconferência interativa. Nossa intenção é trazer ao debate público os resultados alcançados, visando colaborar para a solução de problemas de ensino e treinamento à distância em situações economicamente justificadas pela economia de escala.*

Palavras-chave — *Economia de escala, interatividade, mudança de paradigma, transmissão satelital.*

A EDUCAÇÃO À DISTÂNCIA NO BRASIL

A educação à distância (EAD) no Brasil tem um razoável histórico desde os primórdios do século XX, com base em ensino por correspondência e transmissões radiofônicas, conforme pode ser visto em [1], mas somente passou a se valer das modernas tecnologias da informação e telecomunicação a partir de meados dos anos noventa. A partir de então, registram-se diversas atividades baseadas no uso da Internet, da videoconferência, da teleconferência e de vídeos. Não nos deteremos aqui em tecnicalidades envolvendo esses veículos de comunicação, que os menos afeitos à questão poderão observar em [2].

Com respeito aos veículos citados, devemos considerar que a educação à distância, entendida como um processo de ensino ou treinamento voltado para a formação, tem sido praticada priorizando a Internet, como nos casos da Unirede (rede virtual de univesidades públicas), da UVB – Universidade Virtual Brasileira (rede virtual de universidades privadas), dentre diversas outras, enquanto que o exemplo pioneiro e mais notável de uso da videoconferência em cursos de pós-graduação é o da Univesidade Federal de Santa Catarina, através do seu LED-Laboratório de Ensino à Distância. Mais informações sobre iniciativas em educação à distância no Brasil podem ser encontradas em [3].
